

Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

- + *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.
- + *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.
- + *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.
- + *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. ABSTRACT OF
LECTURES ON MYOLOGY,
AT THE
ROYAL COLLEGE OF SURGEONS OF ENGLAND,
BY PROFESSOR HUMPHRY, F.R.S.
LECTURE II.

THE Professor began by observing that the upper and lower limbs are the produce of similar morphological impulses acting upon serially homological elements; yet that the one limb is not a modification of the other, nor are we certain that both are modifications of a simple common form, though there may be much probability in such a view. After reminding his audience of the statement made in the first lecture that the several muscles of the trunk are derivatives from the same elements as the lateral muscle of the fish, he proceeded to show that the muscles of the limbs are also to a considerable extent derivatives from the lateral muscle. The limb-girdles are ossifications in the transverse septa of the ventral part of that muscle; and as the limbs grow out from the girdles they carry before them ventro-appendicular expansions which become developed into skin, cellular tissue, muscle, &c. The muscular stratum envelopes both limbs to a variable extent, and at the base of each limb spreads out in a funnel-like manner upon the trunk. It is divisible into a superficial and a deep layer. The superficial layer in the upper limb is in three sectors: the *pectoralis*, the *latissimus dorsi*, and the *trapezius* and *deltoid*. These converge upon the humerus, and each, in its course, is connected with the girdle. The connection of the *trapezius* and *deltoid* is effected by the spine of the scapula and the clavicle growing into the septum between these two muscles. This septum is the serial continuation of the

septa of the lateral muscle; and the clavicle corresponds serially with the costal and epicostal bones which form in the abdominal parts of those septa in some animals. The connection of the pectoral sector with the girdle is formed by the *pectoralis minor*, and that of the *latissimus dorsi* by the scapular attachment of that muscle. Parts segmented from the *trapezius* form the *rhomboids*. The superficial ventro-appendicular sheet in the lower limb is still more intimately connected with the pelvis than that in the upper limb is with the shoulder-girdle; and it extends farther upon the limb. It is divided into three sectors: the *gracilis*, corresponding with the *pectoralis*, the *gluteus*, corresponding with the *latissimus dorsi*, and the *tensor vaginae femoris* and *sartorius*, corresponding with the scapular part of the *deltoid*. The external oblique fibres passing to the ilium correspond with the *trapezius*. The crural arch corresponds with the brachial arch; and an ossification in Poupart's ligament would correspond with the clavicle. The aponeurosis of the external oblique, above Poupart's ligament, corresponds with the *trapezius* and the *cleido-mastoid* above the clavicle; and the femoral fascia, below Poupart's ligament, corresponds with the parts of the *deltoid* and of the *pectoralis* below the clavicle.

With regard to the deep ventro-appendicular stratum, it forms a sheath covering the shoulder and hip-joints respectively, and is in each instance divided into four sectors. The dorsal sector forms the *infra-spinatus* and the *teres minor* in the upper limb; and the *gluteus medius* and *minimus* in the lower. The palmar sector is the *coraco-brachialis* and the *subscapularis*, answering to the *adductors* and the *obturators* in the lower limb. The anterior sector is the *iliacus* in the upper limb, and the *supra-spinatus* in the lower; and the posterior sector is the *teres major* in the upper limb, and the *pyriformis* in the lower. In making comparison of the muscles in the upper and lower limbs, and in the limbs of different animals, a very close correspondence must not be sought for the developmental processes in each are freely modified to suit the respective requirements. Thus, the attachments of corresponding muscles are often found to vary, the points of insertion varying as much as those of origin

so that the former are no surer guides to homological comparison than the latter.

Lastly, the Professor spoke of the deep muscles passing from the trunk to the girdles. These are the costo-clavicular, or *subclavius*, the costo-scapular or *serratus*, which is continued forward as the *levator scapulae*, and the *omohyoid*, which is a representative of a much more extensive connection of the hyoidean muscles with the scapula in fish and urodelaans. In the hind limb the *levator scapulae* is represented by the *quadratus lumborum*, the *omohyoid* by some fibres of the *internal oblique*, and the *subclavius* and *serratus* by the *ischio-coccygeus*, and the *ilio-caudalis*. The chief nerves and vessels to the limb pass between the two muscles last mentioned in tailed animals, as those of the upper limb pass between the costo-clavicular, and the costo-coracoid on the one side, and the costo-scapular on the other.

CLINICAL NOTES AND OBSERVATIONS.

BY HENRY LEE,

Surgeon to St. George's Hospital.

XI.—Decomposition of Blood in Living Vessels.

DECOMPOSITION may take place while the blood is yet in the living body. Decomposition once commenced may rapidly be communicated, either by contact, or by the removal of the decomposing blood to a distant part of the circulation.

If a very small piece of cotton wadding be soaked in a putrid fluid and introduced into a vein, in twenty-four hours the blood for many inches up the vein will have formed a dark gelatinous clot, and if left, will soon pass through the various stages of decomposition. The following experiments performed by M. Gaspard, illustrate the mode in which decomposition may go on in the yet circulating blood:—

Experiment.—"Two ounces and a-half of thick fetid fluid, derived from the maceration of cabbage leaves in an equal quantity of water, for two days, at a temperature of 77 Fahr., were injected into the right jugular vein of a moderate sized dog. During the operation, the animal made several efforts to swallow, and soon became faint, and vomited several times. Some hours afterwards there was great uneasiness and oppression, with recurrence of the vomiting, and continued faintness during the day. After nine hours, a most copious very fetid evacuation took place. The discharge was as black as soot, and composed of mucous with a little fæcal matter, and a large quantity of what appeared to be corrupted blood.

Sometime afterwards there was a second evacuation of bloody mucous, exactly resembling the first. On the following day, there was much loss of strength, the animal lay upon its side or staggered as it walked. There was great and insatiable thirst, with a small feverish pulse. But the most remarkable symptom, was the occurrence at intervals of palpitation of the heart, accompanied by extraordinary force and sound, resembling that produced by long continued hypertrophy of that organ in consequence of aneurism of one of the large arteries. On the third and fourth days the animal was better, but there were still great thirst, fever, and occasional rejection of fluids from the stomach. On the fifth day the symptoms became aggravated; there was extreme weakness, a tottering gait, excessive thirst, the eyes red and filled with gum; the nostrils were stuffed, swollen, and obstructed with mucous, and the lining membrane of the mouth was tumid and of a red violet colour. In the middle of the day, there was a liquid greyish white evacuation, resembling pus in its odour, consistence, and appearance, mixed with some clots of putrid blood. Death occurred during the following night.

Post-mortem Appearances.—The mucous membrane of the eyes, nose, and mouth, was red or violet, and covered by a very abundant thick mucous. The lungs were of a dark colour, with some black patches, but still crepitant.

The left ventricle of the heart presented several brown stains, resembling ecchymoses, which penetrated into its tissue. Its internal surface was of the colour of lees of wine, offering a singular contrast to that of the right side, which, however, contained a hard fibrinous concretion, two drachms and a-half in weight, of a light yellow colour, and resembling grease in appearance. This was of the same consistence throughout, every where free, with the exception of a portion of the size of a finger nail, which adhered to an irregular and apparently inflamed spot on the inner surface of the ventricle; no appearance of the injected fluid could be recognised in this clot. It was continued of the same colour and consistence into the pulmonary artery, and into the vena cava, the vena azagos, the axillary, and even the right jugular vein.

The intestinal mucous membrane, especially in the rectum, the duodenum, and a small portion of the small intestines, was of a violet red colour. It was inflamed in longitudinal strips and in patches, which gave a mottled appearance, even to the outer surface of the intestines, before they were opened. This discolouration was not accompanied by any thickening of the tissues, nor by ulceration, and appeared rather the result of ecchymosis or hæmorrhage. The lining membrane of the rectum was principally affected, and its mucous glands were swollen and very prominent. This intestine contained puriform fluid, resembling the matter evacuated before death. The other intestines contained a very thick greyish white mucous. The mesenteric glands were inflamed, and appeared as if infiltrated with blood. The gall bladder was mottled on its surface by brown and violet patches, and contained black, thick, ropy bile, resembling melted tar.

Experiment.—An ounce of putrid water, in which some beef had been macerated, was injected into the crucial artery of a middling-sized dog. The artery having been tied, the pulse ceased below the tendo-achilles; the limb, however, preserved its usual degree of heat.

A considerable degree of fever and restlessness followed the operation; this continued the whole day and the following night, without any vomiting or evacuations, which so constantly followed similar operations upon the veins. The next day the limb was very painful, but not swollen, there was great thirst, with the ordinary secretion of fæces and urine. On the third day the animal was evidently better; the appetite had become almost natural, and he could walk more easily, although the limb was still very painful. In the night there were some soft almost liquid evacuations.

The fourth day the animal was evidently recovering, when an ounce and a half of very fetid and very concentrated fluid (derived from the maceration of beef), was injected into the crucial artery of the opposite limb. The animal immediately evinced pain, accompanied by very violent and remarkable palpitation of the heart. It walked lame, keeping the leg raised, and soon became feverish and uneasy. The symptoms were exactly the same as after the first experiment. The leg became gradually more and more painful, extremely sensitive, but not infiltrated with serum. During the night, there was much expression of pain, and the animal was in continual motion. Death occurred nineteen hours after the second injection. The limb became swollen only within five or six hours before death.

Post-mortem Appearances.—The limb presented a very large quantity of bloody fluid infiltrated in all the tissues; the superficial muscles were black, and presented more or less the appearances of gangrene. The deep muscles existed as such no longer, but were entirely disorganised, and converted into a putrid pulp, resembling masses of the red lees of wine, extremely fetid, and disengaging a quantity of gas. The limb first injected was still swollen, and presented, in the interior of the adductor muscles, two or three cavities filled with a putrid bloody serum. In the chest the lungs were healthy, as were also the right cavities of the heart, but the left cavities presented several reddish black spots, scattered over their external surface. In the left auricle was a firm yellowish white coagulum, adhering

to an inflamed spot on its inner surface. The intestinal canal was filled with a brownish red fluid, resembling altered blood, which in the stomach and duodenum, was of the colour of soot. The mucous membrane of these organs, as well as of the jejunum and rectum were gorged with blood, of the colour of the lees of red wine, but without any inflammatory thickening of their coats.

Case.—A man, named Pettendrigh, 32 years of age, was run over on the 4th of September, 1853, and sustained a severe compound fracture of the leg, for which amputation was thought necessary, two hours after the operation a smart oozing of blood occurred.

September 5th.—Had been in much pain all night; slept a little in the morning; during the day he became somewhat delirious, and tried to get out of bed; the pulse rose to 156, and became intermittent.

September 6th.—Pulse 152; features pinched; skin cold and clammy, but little pain in stump; a dark livid blush ran up the inside of the thigh; on removing the dressing some hæmorrhage occurred, and a vessel was secured. 9 p.m.—Pulse steady and intermittent; profuse perspiration.

September 7th.—Pulse 136, very small; oozing of blood continued; the dark blush extended to the groin, it presented a dark livid, not very defined margin; the discoloration did not disappear upon pressure. 6 p.m.—great pain over the buttock and hip where air could be felt in the cellular tissue. 8 p.m.—Considerable swelling about the hip, which became very tense during the night.

September 8th.—Jaundiced; died at half-past nine a.m. 11 a.m.—Surface of body universally emphysematous, and skin yellow.

Post-mortem examination.—Stump gangrenous; cellular tissue between hamstring muscles and beneath the sartorius sloughing; the lining membrane of the femoral and external iliac vein decomposed and of a brown colour; liver of a dull brownish slate colour, mottled on its surface by air between its lobules; a section of the liver presented a honey combed appearance, as though its structure were expanded and torn apart by the development of gas; vesicles of gas beneath the pericardium on the heart; the areola and adipose tissue of the thigh had a pink appearance, which did not appear to depend upon effusion of blood, the glutei muscles of the left side, and other muscles round the left hip and upper part of the thigh were softened, and in parts presented a dark greenish brown colour, other portions were reduced to a reddish pulp.

On the 10th July, 1826, M. Cruveilhier injected ink into the crural artery of a dog. Great pain immediately followed; the limb hung motionless and insensible; in the evening the skin had become livid, as in ordinary mortification; on the morrow the mortification was confirmed; forty-eight hours afterwards the limb afforded a strong gangrenous odour; amputation was performed above the line of separation between the living and the dead parts; the muscles of the thigh were reduced to a red pulp; the periosteum of the bones, and the articular ligaments between the tibia, femur, and fibula, were detached from the bone, and the articular cartilages were loosened; the putrid alteration was much less at the tibio-tarsal articulation, and below that point, dry gangrene alone existed, and the ligaments were in a state of perfect preservation and the periosteum remained adherent to the bone.

Michael Hern, æt. 40, was operated upon for popliteal aneurism, in the year 1850. The wound healed and the aneurism was cured, the foot, however, became dusky, and five months afterwards, the toes of the affected limb mortified and were removed. This patient was seen on the 20th of October, 1856. The nutrition of the affected limb was then carried on satisfactorily.

In the first of the above cases, we find the body universally emphysematous; the stump gangrenous; the muscles in part reduced to a putrid pulp; the blood in the iliac veins decomposed; the liver of dull brownish slate colour and mottled on its surface by air between its lobules. The effects of decomposition manifested by the development of gas was visible even on the surface of the heart.

In cases where the blood is more or less decomposed in the living vessels, it is often not coagulated. This may depend upon the amount of ammonia generated in the process of decomposition.

Dr. Richardson has attempted to show us that when blood coagulates it parts with its ammonia, and by a well conceived experiment, he has supplied the blood again with ammonia which was deficient, and the blood has again become fluid.

This circumstance appears to afford an explanation of a fact observed some years ago by the author, but which he did not at that time understand.

Some blood, the circulation of which had been retarded in an inflamed vein, was received upon a sponge and placed in hot water. Almost immediately the fibrine of the blood floated in firm shreds in the water. Some of these were collected and placed in a bottle and corked up for further examination. On the following day, the whole of this fibrine had been again converted into a fluid condition. The explanation of this now appears to be, that the ammonia was suddenly driven off by the heat of the water, and that then the fibrine became firm; but when decomposition had sufficiently advanced to generate more ammonia, that then it again became fluid. This explanation, may possibly, in like manner, account for the blood undergoing decomposition in the living vessels without becoming coagulated, or if coagulated again in the process of decomposition, assuming its original fluid condition. If the quantity of ammonia generated in the blood during decomposition be as much as is given off, then it would appear that the blood will not coagulate, or if it has coagulated, it may again become more or less fluid.

Under these circumstances, the colouring matter of the blood will, however, be readily separated, and will stain any part with which it may be in contact, and leave an appearance on the lining membrane of the blood vessels, which has often been mistaken for inflammation.

From the cases and experiments above given, it appears that the action of decomposition commenced in one portion of the blood, may be propagated to any part of, or to the whole system, and unless the action were checked, this would be the usual result. It is remarkable that this does not occur oftener. The current of the circulation is in a peculiar manner open to the influence of portions of liquified fibrine or decomposing blood, after every injury that any vessels sustain, either from accident or disease. The mode in which the propagation of this fatal influence is stopped, is a beautiful instance of the inherent preservative power of the animal system.

One of the first steps towards decomposition is the evolution of ammonia, this also is one of the essential conditions of coagulation of the blood.

The same influence therefore that tends to set up a diseased action in the blood, tends at the same time to limit the disease by producing coagulation of that fluid. It is true that the coagula thus formed may in their turn undergo decomposition, and the products of that decomposition may be the means of infecting other parts.

But in other instances, the coagula remains firm, and prevent the extension of the disease along the blood vessels. The union of separated parts by a thin layer of blood, indicates what Hunter called the "intention," as much, when such a union is temporary only, as when it is permanent, and so the object of the coagulation of the blood in the veins, in cases where the process of decomposition has commenced, appears evident, although the remedial action is not always attained.

Some of the most striking cases of mortification from decomposition of the blood, are to be seen in the severer forms of puerperal fever. In this disease any organ may be attacked, and will run rapidly into decomposition. The tissues will appear to melt away before there is time for any regular inflammatory process to be set up. In reviewing the description of the *post-mortem* appearances in patients who have died under such circumstances, we find such expressions as the following:—"The ligamenta lata and ovaries appeared quite black." "The legs and thighs covered

by an eruption resembling purpura when it first appears," "ovaria disorganised, and in a semi-fluid state." "The uterus of a dark purple colour, its internal membrane soft, nearly black, easily peeling off." "The ovaries soft and pulpy," "a large gangrenous opening in the œsophagus," "all the external parts of generation of a dark livid colour, with numerous ulcerations from vesicles bursting, blood generally fluid, &c." Nor are cases wanting after surgical operations, in which a general contamination of the blood has occurred. In the first of these cases above mentioned, the blood was evidently decomposing in every part of the body, although its effects were naturally more evident in the veins and internal structure of parts, than in the arteries, for the obvious reason that in the first the blood moves more slowly, and is placed under more favourable circumstances for the development of morbid actions. It is remarkable in this case, that while the blood in the iliac veins was "decomposed and of a brown colour," that the glutei and other muscles were "reduced to a reddish pulp." Now this action appears at first sight to have been propagated from the iliac vein to its terminal branches contrary to the course of the circulation. The explanation of this circumstance appears to be, that there are two ways in which a septic agent may contaminate the blood. 1. In the ordinary course of circulation. 2. By the diseased action being propagated by contact to the adjacent parts.

The parts most affected in this case were probably subjected to contamination in both the above mentioned ways, when through the introduction of a septic agent, the stagnant blood begins to decompose, the whole of the constituents of the blood are then together involved in the changes which take place.

An interval, even in the most strongly marked cases, usually elapses between the development of the infecting cause, and the manifestation of constitutional symptoms. This is especially the case where diseased secretions enter the circulation through the nutritious vessels of bone. The morbid matter is detained for a certain time, during which the process of decomposition is established. The first infected portions of blood, together with the morbid matters which they contain, then pass on to infect the blood in adjacent vessels. The dissolved and putrifying fibrine from these, proceeds further towards the centre of the circulation, in its course, it will loosely coagulate fresh portions of blood, and then determine their decomposition. Every additional quantity of blood that is infected, will add to the amount of putrid dissolved fluid in the vessels, and thus the disease will propagate itself, quite independent of the original source, wherever the septic agent is derived.

STUDENTS' COLUMN.

SYNOPTICAL REVIEW OF THE OFFICIAL PREPARATIONS OF THE BRITISH PHARMACOPEIA.

By W. HANDSEL GRIFFITHS, Ph.D., L.R.C.P., L.R.C.S.E.,
Assistant-Librarian Royal College of Surgeons in Ireland.

ENEMATA (INJECTIONS, CLYSTERS).

THESE are substances in a liquid form intended for injection up the rectum either for the purpose of evacuating the bowel (when the quantity of liquid should be large), or for acting medicinally on the neighbouring parts or on the system (when the bulk of the vehicle should be small). There are six of them in the Pharmacopœia, viz.—

1. Enema Aloes.
2. " Assafoetida.
3. " Magnesia Sulphatis.
4. " Opil.
5. " Tabaci.
6. " Terebinthina.

Mucilage of starch forms the basis of all the enemata except *Enema Assafoetida* and *Enema Tabaci* in the former of which cold water is the basis, and in the latter boiling water.

The following are the formulæ:—

	Active Ingredient.	Basis.	Other Ingredients.
<i>E. Tabaci</i>	Tobacco leaf .. 20 grs.	8 ounces	
<i>E. Assafoetida</i>	Assafoetida .. 20 grs.	4 ounces	
<i>E. Aloes</i>	Aloes 40 grs.	10 ounces	Carbonate of Potash (15 grains.)
<i>E. Opil</i>	Tincture of opium ½ drms.	2 ounces	
<i>E. Magnesia Sulphatis</i>	Sulph. of magnesia 1 oz.	15 ounces	Olive oil 1 oz.
<i>E. Terebinthina</i>	Oil of turpentine .. 1 oz.	15 ounces	

ESSENTIÆ (ESSENCES).

Of these there are only two in the Pharmacopœia, viz:—

1. *Essentia Anisi.*
2. " *Menthae Pipentis.*

They are solutions of 1 part of the volatile oil in 4 parts of rectified spirit.

EXTRACTA (EXTRACTS).

These are preparations obtained by evaporating solutions of vegetable principles. They may be conveniently divided into classes according to their method of preparation.

CLASS I.—FRESH OR GREEN EXTRACTS.

Preparation.—The juice pressed out from 112 pounds of the bruised plant is heated to 130° F. to coagulate the green colouring matter; this is then filtered off, and the fluid is heated to 200° F. to coagulate the albumen, which is separated by filtration. The fluid is now evaporated at not above 140° to a thin syrupy consistence, the green colouring matter, which was separated in an early stage of the process, is added, and the whole evaporated down to the required consistence.

The following are the Extracts thus prepared, with the parts of the plant used:—

- E. Aconiti* (Fresh leaves and flowering tops).
- E. Belladonna* (Fresh leaves and young branches).
- E. Conii* (Fresh leaves and young branches).
- E. Hyosclami* (Fresh leaves and young branches).
- E. Lactucæ* (Flowering herb).

Another group of Extracts belonging to this Class are prepared by heating the juice at once to 212° F. to coagulate the albumen, filtering, and evaporating to a proper consistence at 160°.

The Extracts thus prepared are:—

- E. Colchici* (Fresh corns without coats).
- E. Colchici Aceticum.*
- E. Taraxici* (Fresh root).

In the preparation of *Extractum Colchici Aceticum* 7 pounds of the corns are heated with 6 ounces of acetic acid before the juice is pressed out. The quantity of taraxacum root used in *Extractum Taraxici* is 4 pounds.

CLASS II.—AQUEOUS EXTRACTS.

Prepared from drugs (1 pound is the quantity directed in each case) by the action of cold or boiling distilled water, and subsequent evaporation to a proper consistence (a).

1.—Prepared by digestion in boiling water.

- E. Aloes Barbadosensis.*
- E. Alges Socotrina.*
- E. Farcisæ.*

2.—Prepared by infusion in boiling water and subsequent boiling.

- E. Gentiana.*
- E. Haematoyli.*

3.—Prepared by decoction.

E. Anthemidis.

4.—Prepared by maceration in cold water.

- E. Calumbae.**
- E. Glycyrrhizae.**
- E. Krameriae.**
- E. Quassiae.**
- E. Opii.**

In all the foregoing Extracts, except those prepared by maceration in cold water, the quantity of water used is 1 gallon. In *Extractum Opii* the opium is macerated with 6 pints of water; in *Extractum Calumbae* and *Extractum Glycyrrhizae* the drug is macerated with 4 pints of water; while in *Extractum Krameriae* and *Extractum Quassiae* a sufficiency of water is directed. In *Extractum Anthemidis* 15 minims of oil of chamomile are directed to be added after the evaporation.

CLASS III.—ALCOHOLIC EXTRACTS.

Prepared from drugs (1 pound is the quantity ordered in each case, except in *Extractum Colocynthis Compositum*) by the action of rectified spirit, rectified spirit and water, or proof spirit, and subsequent evaporation to a proper consistence (a).

1.—Prepared with rectified spirit.

- E. Cannabis Indicae.**
- E. Physostigmatis.**
- E. Nucis Vomicae.**

In *Extractum Cannabis Indicae* and *Extractum Physostigmatis* the drug is treated with 4 pints of cold spirit; in the former Extract the process is one of maceration, and in the latter percolation is employed as well. In *Extractum Nucis Vomicae* the drug is steamed, rapidly dried, and pulverised, and then boiled with successive portions of spirit until the latter comes off free from bitterness.

2.—Prepared with rectified spirit and water.

- E. Jalapae.**
- E. Rhei.**
- E. Lupuli.**
- E. Papaveris.**

In the preparation of *Extractum Jalapae* the drug is macerated in 4 pints of spirit and 1 gallon of water successively, as the action of the water is facilitated when the resin is abstracted by the spirit. In *Extractum Rhei* the drug is macerated in a mixture of 10 ounces of spirit with 5 pints of water. In *Extractum Lupuli*, after maceration in 1½ pints of spirit, the residual hop is directed to be boiled with 1 gallon of water; and it must be remembered that in the preparation of *Extractum Papaveris* also boiling water is ordered.

3.—Prepared with proof spirit.

- E. Colocynthis Compositum.**
- E. Stramonii.**

The student should very carefully distinguish between the *Extractum Colocynthis Compositum* and the *Pilula Colocynthis Compositum*. The composition of the latter will hereafter be considered; the following are the ingredients of the former:—Colocynth pulp (6 ounces macerated in 1 gallon of proof spirit), Extract of Socotrine Aloes (12 ounces), Resin of Scammony (4 ounces), Hard Soap (3 ounces), and Cardamon Seeds (1 ounce). In the preparation of *Extractum Stramonii* the oil of the seeds is removed by the action of washed ether before percolation with the spirit.

CLASS IV.—ETHERIAL EXTRACTS.

E. Mezerii Etherium.

Prepared by maceration of 1 pound of the drug in 8 pints of rectified spirit and evaporating to form a spirit extract; the latter is then macerated in one pint of ether and again evaporated.

Ether is also employed in the preparation of *Extractum Stramonii*, *Extractum Ergotae Liquidum*, and *Extractum Filicis Liquidum*,—in the two former to free the preparation from oil, and in the latter as a solvent of the active matter.

CLASS V.—LIQUID EXTRACTS.

These are fluid preparations in which the solvent is water with rectified spirit added as a preservative (a).

They are:—

	STRENGTH.
E. Ergotae Liquidum	} 1 in 1.
E. Belse Liquidum	
E. Pareirae Liquidum	
E. Sarsae Liquidum 2 in 1.
E. Cinchonae Flavae Liquidum 4 in 1.
Opii Liquidum 1 in 20 (of [extract]), or 1 grain in 22 minims.

These liquid Extracts may, in general terms, be said to be prepared by maceration of the drug in water, evaporating the aqueous infusion, and adding spirit to prevent decomposition. The *Extractum Opii Liquidum* is prepared by digestion of the extract of opium in water, adding the spirit and filtering. Cold water is used in all cases except *Extractum Pareirae Liquidum* (boiling water) and *Extractum Sarsae Liquidum* (water at 160° F.). In the preparation of *Extractum Ergotae Liquidum*, as has been mentioned, the ergot before maceration is directed to be percolated with washed ether, the object of which is to remove all the poisonous oil. The ether is washed to ensure its freedom from alcohol, which is a solvent of the active principle.

The so called *Extractum Filicis Liquidum* is rather an Etherial Extract, and is simply made by percolating 8 pounds of the drug with 4 pints of ether.

REGISTERED FOR TRANSMISSION ABROAD.

THE

MEDICAL PRESS AND CIRCULAR

is published simultaneously in London, Dublin, and Edinburgh, every Wednesday morning. Price 5d. Post free, 5jd.

POST FREE TO ANNUAL SUBSCRIBERS £1 2 6
" IF PAID IN ADVANCE 1 0 0

* Post-office Orders and Cheques to be drawn in favour of—
A. A. TINDALL, 20, King William Street, Strand, London, W.C.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, JULY 3, 1872.

CHOLERA.

WE received too late for notice in our last issue a paper by Mr. J. N. Radcliffe, which Mr. Simon thinks important enough to be brought under the notice of foreign Govern-

(a) For details of the preparation of these reference must be made to the “Pharmacopoeia.”

ments, as well as that of Great Britain, and which, therefore, demands a few words at our hands. It has been commonly supposed that the recent outbreaks of cholera in Russia were signs of a recrudescence of the epidemic of 1865. Even Dr. Pelikau, the eminent Director of the Imperial Medical Department of Russia, looked upon the recent diffusion of the disease in Europe in this light. On the other hand, able observers have thought that cholera is becoming naturalised in Persia, and will thus prove a new danger to Europe.

In the report before us Mr. Radcliffe remarks that the prevalence of cholera in Persia cannot be rightly studied without studying also the prevalence of the disease in India. In 1867 cholera had broken out with much fierceness among the multitude of pilgrims assembled at Hurdwar for the great annual religious Hindu fair; the disease followed in the track of the pilgrims returning northwards into Afghanistan, and towards the close of the year it was prevalent in Cabul. In 1869 it became epidemic over the whole of the Bombay Presidency and Northern India, and had a new spread into Afghanistan. The great trade route through Persia and India, through Afghanistan, by way of Herat to Meshed, has been the track chiefly followed in previous invasions of Persia by cholera migrating from Northern India; and Meshed, from its large commerce as the principal centre of trade between the two countries and Afghanistan, and also from its being the focus of a great pilgrimage from all parts of Persia, has always played a very influential part in the diffusion of cholera when the disease has been introduced there. Persia was probably infected from India in 1868-70 by re-importation from India along the lines of traffic just referred to, and not by a re-kindling of the embers of the old epidemic of 1865-67. The parallelism between the recurring activity and continuance of the disease in Persia and Russia is referred to in connexion with this, and a common mode of origin and spread for the two countries is suggested as probable. The disease reappeared in Russia in 1869 at the very time that it was epidemic in Northern Persia, but it could not be traced as an extension across the Russo-Persian frontier. Further, this outbreak occurred coincidentally with the development of a comparatively direct and more quickly traversed route of traffic between Persia and South Russia, viz., that which, traversing Trans-Caucasia from east to west, and having Tiflis at about its mid-point, brings the Black Sea into free relations with the Caspian and with Northern Persia; a route which within the last few weeks has had a railway opened for its western half, and of which the eastern half is in course of having the same accommodation provided for it. By the completion of the line of railway between Odessa and Kiev in 1869, continuous railway communication was established through Russia, between Northern Germany and the principal Russian port on the Black Sea; and, by the recent completion of a railway between Odessa and Jassy, the former place has been brought into connection, by way of Cernowitz, with the railway system of North Germany and Western Europe, and a direct railway route established between the coasts of the North Sea and of the Black Sea. In proportion as the projected line of railway between Poti, Tiflis, Elizabethpol, and Baku is carried out and brought into operation the present augmented speed of traffic between Persia and Russia will be further accelerated, and Persia be brought into closer connexion with Europe. With the completion of

the Trans-Caucasian Railway it may be anticipated that this will follow (to use a modification of Mr. Simon's own phrases applied to the relation of the Continent to this country in respect to infectious diseases), namely, contagions current in Persia will become current in Europe. From this point of view the internal state of Persia, and the recurring famines which afflict its population, will become a subject of nearer interest and greater moment to European nations than was apprehended even by the International Sanitary Conference of 1866.

The reader will at once perceive the great importance of the subject to which we have thus drawn attention. The fact that Mr. Simon thinks there is a real danger is sufficient to justify his suggestion that the report should be furnished to other Governments, and we presume the Foreign Office will lose no time in forwarding a copy.

SURGERY OF THE FRANCO-GERMAN WAR.

(Continued from page 563.)

VI.

A naval lieutenant was wounded by a fragment of a shell on 15th January, 1871, the tibia and fibula of the right leg fracture without a wound of the soft tissues. Both bones were reduced to fragments at the seat of injury, and one fragment having projected through the skin, was replaced. The limb was greatly swollen, there being also a violent contusion above the right knee. Extension and counter-extension were used, and the parts being got in position, the limb was immobilised in a *gouttiere*, and submitted to cold irrigation during three days. Beyond slight febrile disturbance for a few days the patient suffered from no complication, and the progress of the case was satisfactory in all respects.

A naval lieutenant was wounded on 19th January, a splinter of a shell fracturing both bones of the right leg at their lower third, inflicting at the same an extensive wound upon the soft tissues on the inner aspect of the limb. There was, however, an extensive contusion of the outer aspect of the right thigh. Extension and counter-extension were used to bring the fractured parts into position, the limb placed in a *gouttiere*, and irrigation with cold water applied during four days. There was no reaction till the 25th. On that day heat of skin occurred, the pulse was 90, an erysipelatous blush appeared around the wound, with swelling of the parts; the eschars were being detached from the surface. At this time aconite was administered internally, the wound dressed with a powder consisting of quinine, camphor, and charcoal. The erysipelatous blush soon disappeared, but on the 27th attention was drawn to the occurrence of suppuration in the left thigh; the pulse was still further increased in frequency, and the expression of the face altered. During the night the patient muttered in his sleep; he was seized with vomiting. Quinine and aconite were now administered to him. On the 30th suppuration had extended along the whole thigh as far as the hip; the patient had become very weak, and suffered much from vomiting. On the 31st two free incisions were made along the outer aspect of the left thigh, and a large quantity of sanguineous pus evacuated. The state of the bowels was that of obstinate constipation. On 1st February shiverings, followed by fever and bilious vomiting; pulse 110; frequent vomiting, tongue foul,

an additional incision was made into the left thigh, the tissues of which were much undermined by the suppuration. Meantime the progress of the wound itself is described as satisfactory. From this date, however, the patient rapidly became worse and worse, repeated shiverings occurred, succeeded by febrile attacks; weakness increased, and on the 7th of February he sank and died.

A sailor was wounded on 26th January by an exploded bomb, the right tibia being fractured comminutely by the fragment which traversed the soft parts *en seton*. Extension and counter-extension being used to bring the parts into position, the limb was placed in a *gouttiere* and immobilised, irrigation with cold water being used during the first nine days. The progress of the case was normal, except that obstinate constipation was present, requiring the use of lavements, and of sulphate of magnesia; it was observed, however, that the patient was restless, rendering it a matter of difficulty to maintain the limb in position. Suppuration was abundant. On the 6th of February the dressing of the wound gave rise to great pain, and in the course of that day the patient became attacked with tetanic stiffness in the muscles of the neck, and some difficulty in swallowing; at this time, however, the pulse was full, and there was nothing unusual in the aspect of the wound. The treatment employed consisted in the administration of chloral 4 grammes, and extract of opium 10 centigrammes alternately every three hours, portions of chloroform being applied to the temporal regions. On the 7th there was opisthotonos, severe pain in the gluteal regions and excessive perspiration; the pulse 110 and compressible. Infusion of Linden tree, chloral, 3 grammes every six hours; extract of opium 0.20 centigrammes in twenty-four hours alternated with the chloral were now administered. The condition of the patient, however, continued unrelieved, and on the 9th he died asphyxiated. The state of the wound all the while continued clean.

Foot.—A gunner sustained an extensive contusion of the right foot on 29th October, the member getting jammed between the breech and traverse of a gun, and two lacerations of great extent being produced, the one on the dorsum and outer aspect, the other on the inner, and deep. The foot was at once placed in a *gouttiere*, immobilised, and cold irrigation applied. These caused no constitutional disturbance, and by the 8th of December the eschars had begun to separate, and the surface of the wound to become clean. On the 12th swelling re-appeared, the wound on the sole of the foot became sphacelus, being treated then and for several days with coal-tar soap, powder of camphor, quinine and charcoal, tonics being administered to the patient. Under these measures the wound cleaned, normal suppuration took place, recovery rapidly progressed, and on 10th February the patient was sent out convalescent.

A sailor was wounded on 30th November, by a bullet, which entered the sole of the left foot in front of the heel and escaped between the great and second toe, destroying a portion of the second phalanx of the second toe. For eleven days the progress of the case was satisfactory. On the 19th December the patient complained of difficulty in swallowing, but there was no material increase of this for four days, the patient meantime complaining of feeling cold and being sleepless. On the 17th he was seized with severe headache with painful cramps in his

lower extremities and abdomen; afterwards with episthous. Chloral was administered freely, as also opium; frictions with chloroform liniment applied to the articulation of the lower jaw and to the neck, and hypodermic injections of morphia, sulphate of soda being given in the form of lavement. On the 22nd he died.

A gunner was wounded by a shell on 3rd December, a fragment destroying the three first toes, and injuring the first two metatarsal bones. A flap from the plantar region was as far as possible obtained, but there occurred a good deal of swelling of the injured part, although without fever. The subsequent applications consisted of simple dressings, lotions of carbolic acid, ointment of styrax; afterwards dressings with aromatic wine and powder of quinine and camphor. By the 10th of February recovery had far advanced, and the patient was discharged convalescent to a *succursalle* of the ambulance.

A fusilier of marines received a rifle bullet on 21st December, the first phalanx of the left great toe being fractured. The state of the patient was perfectly good till the 9th of January, when he had an attack of shivering followed by erysipelas of that foot, swelling of glands as far as the groin, with dry tongue and constipation. By the 20th an improvement in his state had taken place; the erysipelas had decreased, although followed by a certain degree of turgescence, and the limb free from pain. On the 31st he was seized again with shivering, succeeded by intense fever, with pain in the region of the liver, and bilious vomiting; on each of the two succeeding days he was similarly attacked with shivering. On 2nd February the skin had assumed a jaundiced tinge; it was evident that the patient was pyemic, and on the 3rd he died.

A quartermaster was wounded by a shell on 23rd January, the two first metatarsal lines of the left foot being fractured, and the great toe carried away, the neighbouring soft parts much lacerated. The report of the case states that its progress was favourable till the 12th of February, but the treatment followed is not recorded. On that date severe fever came on, without shivering; on the following day it returned, being preceded by shivering, and then the first indications of *pyæmia* became apparent. Quinine and aconite were given, but symptoms increased in severity, and on the 14th severe pain in the region of the liver declared itself. On the 15th the hepatic pain became still more severe; there was profuse perspiration, with frequent returns of bilious vomiting. On the 19th the surface was jaundiced, the hepatic pain still intense; the state of the bowels was normal, but weakness was extreme; the tongue clean and moist. In the course of the day the patient sank and died.

Multiple Injuries.—We learn that seventeen cases of wounds in more parts of the body than one were admitted; but the following will be sufficient as illustrations of the progress of the more important:—A gunner was wounded on 6th January by an exploded shell, one fragment of which inflicted a small wound on the left knee in advance of the patella, other two injuring both eyes—the right severely—with escape of the humors into the anterior chamber. Severe febrile reaction occurred in this case, and continued during twenty days, for which venesection to the extent of 250 grammes was practised, and the nape of the neck cupped; emollient lotions applied to the eyes, and cataplasms to the knees. The state of the bowels was regulated by calomel and castor oil. The left eye recovered

in about fifteen days, but at the end of the month of January the contents of the right were still being evacuated in the discharges from the conjunctiva, and the ball decreased in size. A free discharge set in from the wound of the knee; the pus serous, and the joint itself became the seat of great pain. An attempt was made to immobilise the limb, but the restlessness of the patient rendered this impracticable. On the 1st of February a severe accession of fever again came on, but without shivering; the discharge from the knee diminished, but continued abundant from the right eye; the patient became delirious, and this state of matters continued throughout a week, the discharge from the knee becoming sanious, the patient so low as to void his stools involuntarily. During this time he was treated with tonics and support; quinquina, iron and tincture of aconite. These symptoms improved after the 10th of the month. The pulse rose; diarrhoea, from which the patient had suffered, diminished; suppuration returned in the knee, modified in its quality. On the 12th fever had ceased; the powers of body and mind were being restored; the patient called for food. Suppuration of the knee now became phlegmonous and abundant; the expression of face improved, and from this time the patient progressed favourably in convalescence.

Notes on Current Topics.

Epithelioma Uteri removed by Galvano-Cautery.

The progress of electro-therapeutics is manifest in all directions. One of the more recent communications that has arrested our attention was made to the New York Obstetrical Society, and is reported in the *American Journal of Obstetrics*. We are told that—

“Dr. Jas. L. Brown presented a specimen, and related the following case:—The specimen presented is a cervix uteri, which was removed eight days ago. Dr. Brown first saw the patient from whom this was removed one year ago, when she consulted him on account of sterility. She was then twenty-two years of age, was in good health, and had been married fifteen months, and was anxious for children. Examination at that time showed that the uterus was retroverted, and that the os was in a condition of granular erosion. The position was rectified by the use of a pessary, and the erosion cured by the use of nitrate of silver. Four months after the menses became suppressed, and she believed herself to be pregnant. After four months of suppression she consulted Dr. Brown, who found the uterus of normal size, and no evident cause for the suppression. Two weeks ago she again consulted the doctor, and stated that she had not menstruated for nearly ten months, and had had no leucorrhœa. She visited the doctor to ask if he did not think a sea voyage would be beneficial to her. Dr. Brown re-examined the patient at this time, hardly expecting to get any additional clue to her state; but he now found a ring of roughened tissue around the os uteri, which was a commencing epithelioma. Dr. Thomas saw the case in consultation, and confirmed the diagnosis, and a few days after Dr. Brown removed the diseased portion of the cervix by the galvano-cautery. There was no hæmorrhage during the operation, and the patient did well until the fifth day, when a slight attack of pelvic peritonitis occurred, from which she soon recovered. Dr. Brown further remarked that in this case there had been no uterine symptoms to give suspicion of the developing disease, and had he not by accident examined the patient, but have allowed her to proceed on her voy-

age, she might not have returned alive, or, at least, the disease would have been developed beyond the reach of surgical aid.

“Dr. Noeggerath said he had examined Dr. Brown's specimen microscopically, and found it to be a most characteristic case of epithelioma developed in the epithelial cells of the papillæ.

“Dr. Byrne said the presence or absence of uterine symptoms give no good guide to the condition. Last Christmas he removed a part of the cervix under circumstances similar to the case of Dr. Brown, and the patient made a good recovery. A few days ago, however, the same patient came to him on account of pain in the bladder and neighbourhood, while she suffered deplorably from an intermittent pain, coming on at four in the morning and lasting until morning. She has severe backache and frequent desire to urinate. On examination, the remaining portion of the cervix was found indurated and very sensitive to touch, and pressure upon the indurated portion gave the pain of which the patient complained. The uterus was normal in size and position. Dr. Brown proposes to remove the remaining portion of the cervix. Within the last three weeks he has removed the cervix in two cases by the galvano-cautery; in one case on account of hypertrophic elongation inducing sterility, and in the other on account of epithelioma. No unpleasant symptoms followed either case.

“Dr. Noeggerath remarked that there are two classes of cases as regards the reaction following the use of the galvano-cautery: in one class there is much reaction, while in the other but little. In most cases of malignant disease there is no reaction. If the cervix is removed for induration or chronic congestion, inflammation sometimes results; in some cases the reaction is very severe. He once had a patient who was obliged to remain in bed for two months after its use. The inflammation usually begins at the supra-vaginal portion as a circumscribed cellulitis, and sometimes extends to the peritoneum. In regard to the pain, there is usually less suffering in the early stages of cancer than in other diseases, and there is no pain which can be said to be specific or characteristic of cancer.

“Dr. Budd remarked that the fœtid discharges which are so often spoken of as characteristic of cancer are not peculiar to that disease, for there are many cases in which there is neither pain nor fœtor. He has usually found absence of sensibility in malignant induration, whilst in inflammatory induration he usually finds much sensitiveness.

“Dr. Peaslee agreed with Dr. Budd in reference to fœtid discharges, which are no proof in themselves of cancer. We may have the peculiar discharge alluded to, occurring whenever we have blood or tissue undergoing decomposition. During the ulcerative stage we have odour, so also in cases of retained dead fœtus; and a similar odour is usual after removal of fibroids. Though the discharge is no proof of cancer, it should always arouse suspicion. With reference to pain,—usually there is no pain in epithelioma, and in many cases of scirrhus there is no pain, while in chronic metritis there is often a great amount of pain. The cachexia in these cases may also not exist.”

Mammary Tumours.

We learn from the *Transactions* of the New York Obstetrical Society that, at a meeting held in May last,—

“Dr. Noeggerath exhibited two mammary tumours from different patients. The smaller tumour was about the size of an English walnut, and was removed last November from a patient upon whom he had operated for a similar tumour eight years ago, which was about the size of a hen's egg, freely moveable, and occasioning but little pain, but as it began to enlarge it was thought best to remove it. The tumour exhibited was in the same breast as its predecessor.

“Last Saturday he removed the other tumour exhibited,

which was somewhat larger than a man's fist. The patient was thirty-three years of age. She first noticed a small tumour at the age of sixteen situated on the upper and left section of the right mamma, which gave her no pain, and developed slowly during a period of eight years. At the age of twenty-four she married, the tumour at that time being about the size of a walnut. During her first pregnancy the tumour grew more rapidly, so that at the end of gestation it was the size of a hen's egg. After delivery the whole breast developed to the size of a foetal head, and was in a state of sub-acute inflammation. During the subsequent gestations the tumour increased, but it was not until the fourth that she suffered any pain. Two and a half years ago, after the birth of her fifth child, the breast again swelled and became very painful. From that time until now there has been but little increase in size, though the pain increased to such an extent as to render her unable to attend to her household. At the time of removal of the tumour the patient looked well, but was suffering from lancinating pains in the breast. Palpitation showed the entire gland tissue to be the seat of a nodular tumour confined to the gland tissue itself; the sub-cellular, fatty, and muscular tissues were apparently not involved. The tumour presented two peculiarities in its history: first, its slow growth; second, the large amount of pain, which could not be explained by tension of the tissues, as that did not exist. On incising the tumour after its removal, it was found to consist of a number of separate tumours of a greyish white colour; these were confined to the gland itself. The two tumours exhibited were capsulated and microscopically found to be true adenoid sarcomata, a class of tumours on the edge between benign and malignant growths. It is impossible to tell whether such tumours will recur. Virchow and others have reported cases where such tumours reappeared after removal; usually, however, they do not recur. It has been observed that such tumours take origin in the epithelial cells of the gland. These tumours are usually isolated, but are locally infectious, invading the skin and giving symptoms of true cancer. Where the nature of the tumour is doubtful it should be removed."

Cimicifuga as a Preventive of Small-pox.

In an interesting report on the topography and diseases of Madison county (*Atlanta Med. Jour.*), Dr. G. D. Norris stated that "during the prevalence of small-pox in Huntsville, certain families, at the instance of some one unknown, had resorted to the free use of the tea of the *cimicifuga racemosa*, or black snake root of the Pharmacopœia (*cohoosh*), as a preventive of small-pox. In the families using the cimicifuga, there occurred no case of small-pox, though some were exposed to the disease. In the same families, Dr. Norris vaccinated the members, but without effect so long as they continued the use of the cohoosh; after ceasing to use the tea as a prophylactic, he again vaccinated them, when the specific effects of the vaccine virus were produced. He submitted the results in these cases as new.

Effects of Menstrual Disorders on the Eye.

Dr. REUBEN VANCE, *Boston Med. and Surg. Journal*, May 9th, says that the phenomena of menstruation may be associated with disordered vision, and it is possible that such visual disorders are due to the general commotion to which the female organisation is subjected at this time. He has seen a number of cases when photophobia and dimness of vision were complained of at the monthly period, in which the ophthalmoscope did not reveal any disorder of the intra-ocular structure, and others again

when hyperæmia of the disc and retina to a very marked degree, occurring at the same time was unattended by any defect of vision. A young woman who became the victim of morbid desires and vicious impulses at each menstrual period, but she was in perfect mental and physical health at all other times, gave no other evidence of cerebral disorder than such as was revealed by the ophthalmoscope. The vessels of the disc he says are enlarged, and their numbers increased in such cases and the disc may even assume a crimson hue.

Tracheotomy.

At a meeting of the St. Louis Medical Society on May 4th, Dr. Hodgen remarked on tracheotomy for croup and diphtheria, that he had operated on nineteen cases, three of which had proved successful. He described his mode of operating as follows: Pinch up the skin in a transverse line, passing half an inch below the cricoid cartilage, and transfix in a line with the middle of the neck, making a cut two inches long, through skin and areola tissue; now make the cricoid cartilage the objective point, and with two forceps tear the tissues covering the anterior part: this reached, extend the dissection with forceps as deep as the isthmus of the thyroid body, and an inch below the cricoid. Pass a grooved director or other blunt instrument between the isthmus of the thyroid body and the trachea, separating the connective tissue between them. With an artery forceps seize the isthmus of the thyroid body, by placing one blade under and the other in front of it, with the handle of the forceps towards the chin. Now turn the handle of the forceps towards the chest, thus inverting the isthmus of the thyroid body, and leaving the four or five upper rings of the trachea exposed. Fix a tenaculum in the cricoid cartilage, and give it into the hands of an assistant.

The step to which I wish to call attention particularly, is the manner of *introducing the tube*. Here I use an instrument made by bending a hair-pin at an obtuse angle about three-quarters of an inch, from the looped end, on a plane passing through the two limbs. This instrument is held in the left hand by the side of the blade of the knife, with the point of the knife projecting one-fourth of an inch beyond the loop of the hair-pin. The point of the knife is thrust through the trachea at the lowest end of the proposed incision, the hair-pin pressing on the flat surface of the knife, and as the cut is extended upward, the hair-pin is slipped into the trachea by the side of the blade, and when the knife is withdrawn, the hair-pin is turned with its point into the trachea and the limbs at right angles to the passage. With the little finger of the surgeon's left hand on the lowest part of the neck, the hooked hair-pin easily follows the movement of the wind-pipe. The trachea-tube is now passed along the upper surface of the two limbs of the hair-pin, which serves not only to hold the cut open, but is an admirable guide for the tube.

After Management.—Temperature of air in room should be about 70°, with the dew point at 68°. A sponge or piece of folded flannel should be wet in warm water and placed over the free end of the tube and changed every ten minutes. The inner tube should be removed and cleaned when mucus collects in it. If it be found that a crust has formed at the inner end of the outer tube, it should be replaced by another.

I am sure I have known several children die from neglecting the temperature and moisture of the air of the room, allowing dry crusts to form at the inner end of the outer tube. A dry feather may be used to remove soft secretions from the tube, being always cautious not to allow the feather to pass beyond the end of the tube into the trachea. A patient after the operation should never be left without some one competent to remove and replace the tube.

The Postman.

PROFESSIONAL and other friends have expressed "doubts" as to the very peculiar position in which our letter carriers are placed—with regard to work, pay, and pensions—as submitted to the public by means of our columns. To remove all further "doubts" on the subject, we append, *verb. et lit.*, the six "points" of the petition forwarded in March last by our adhesive friends to the Postmaster-General; and as, since that time, no reply has been received to the document, we feel confident, from facts that have come to our knowledge, that the appeal has not been wholly disregarded. Time brings changes, and surely changes with advancement must be the result in our friends' case.

1st.—That our annual holidays be assimilated to those of the inland and newspaper branches, viz., the first and last two months of the year be left optional.

2nd.—That the barrier by which a letter carrier has to be in the Post-office service twelve years before he can obtain 26s. per week be abolished, and that the annual increase be continuous until the maximum amount of pay be arrived at, and that the maximum be increased to 35s., rising by an annual increase of 1s. 6d. per week.

3rd.—That an immediate increase of 10 per cent. be granted.

4th.—That promotion to other branches of the minor establishment be open to letter carriers (by seniority), provided the candidate is competent to undergo the required examination, all such promotion to be made without any loss of pay.

5th.—That vacancies in other departments or branches of the minor establishment for which letter carriers are eligible be published in the *Official Circular*, as also a list of subjects in which the candidate will be examined.

6th.—That the present rates paid for extra duty when summoned officially be revised.

We certainly consider that the pay of our letter carriers should not commence at a less sum than 25s. per week, and receive an annual increase until a maximum of 40s. per week be reached. At present it commences at the munificent weekly stipend of 18s.; increases 1s. per annum until 25s. be reached, and then stops short for some years.

Blue Light as an Organic Stimulant.

THE May number of the *Medical Cosmos* which has just reached us, opens with an abstract of a paper on this subject. We are told that, at a recent meeting of the Philadelphia Agricultural Society, according to the *Philadelphia Inquirer*, "General Pleasanton read an interesting paper on the effects of sunlight on plants and animals when transmitted through blue glass. About one year since, Mr. Pleasanton read before the Society a similar paper, which has since given rise to so much discussion, that he proceeded now to communicate some facts in connection with the subject, very curious, instructive and interesting. After alluding to the hail storm which visited this city in the month of May, of last year, during which so much injury to hot houses had been inflicted, Mr. Pleasanton stated,

among the sufferers was Mr. Robert Buist, in his grape house near Darby, who at that time had a very large and valuable collection of geraniums which had become disordered; many had died, others were feeble and withering. It occurred to him that if he should paint, with a light blue colour, the inside surface of each pane of glass in one of his houses, leaving a margin of an inch and a quarter in width of the glass in its uncoloured condition all around the painted surface, and then place his sickly geraniums under it in the house, the vigour of his plants might be restored. The experiment was tried, and at the end of ten days their vigour was not only restored but their colour was greatly intensified. The experiment was also tried in various other portions of the country with equal success. A remarkable circumstance in these experiments was that the combination of the sunlight with blue light destroyed those noxious insects so destructive to vegetation.

"Mr. Pleasanton continued:—'For purposes of ventilation in the grapery I had caused to be removed from below the eaves, on the south eastern side of the house for the whole length, two panes of glass, and in their place introduced galvanized wire cloth, with meshes of about one-quarter of an inch square. The vines planted on the outside border had, when they reached this wire cloth on the inside, sent latent branches through its meshes, which had grown to varying lengths of ten to fourteen feet on the outside of the grapery. These latent branches were covered with foliage. The inside branches, from the same stems, extending to the ridge were likewise covered with the densest foliage, but the difference between the inside and the outside foliage was most distinctly marked. The inside leaves were fully six or eight inches in diameter, of the deepest green colour and perfectly healthy. Those on the outside were only two inches in diameter, and of a pale sickly yellowish colour, indicating a feeble vitality.' The opinion deduced was that this example furnished the most conclusive illustration of the influence of blue light on vegetation. By Professor Brainerd and others, it was thought to be one of the greatest discoveries of the present century."

The paper then alluded to the vitalizing influence of this discovery in the cure of human and other animal diseases. The case was cited of the wife of a physician of this city, who was suffering from a complication of disorders which had baffled the skill of some of the most eminent physicians. Mr. Pleasanton recommended the trial of blue light. The patient was found in a very miserable condition, unable to eat or sleep, and rapidly wasting away. The plan was tried. Every other pane of glass in one of the windows of the sitting room was removed, and blue glass substituted. The patient was then required to expose her back and spine to the action of the combined blue and white lights for thirty minutes, each day, at the same hour. At the end of ten days, the pains in her back were less, the hair had commenced growing thickly upon her head, and there was a general improvement in her condition. In three weeks she was almost entirely well. The physician remarked that from his observations of blue light he regarded it as one of the most powerful tonics, and as the greatest stimulant he knew of in medicine, and as valuable in cases of typhoid fever and debility.

ON Wednesday, the 26th ult., Dr. Arthur Farre, F.R.S., delivered the Harveian Oration, at the Royal College of Physicians of London.

The Supply of Food by the Importation of Preserved Meat.

THE Food Committee of the Society of Arts - a tribunal which has already done the best service in pursuing an intelligent and disinterested inquiry from year to year into one of the most important social subjects—has just issued to the parent society its annual report. The Committee have not yet examined any meat which, having been once thoroughly dried, can be recommended for general use in this country as an article of food. The meat becomes hard, and its juices either destroyed or permanently coagulated, so that no means hitherto adopted have been successful in restoring it to a palatable condition, or acquiring for it a nutritive value.

Various specimens of tinned meats from Australia and elsewhere have been tested by the Committee. There are still several points calling for improvement in the preparation of these meats, and the Committee is of opinion that much still remains to be done in the application of heat to prevent overcooking, and consequent insipidity and general deterioration as an article of food.

The Committee issued questions to various institutes, in order to obtain the result of the experience gained in such establishments. In fifty cases the meat, beef or mutton, has been more or less used, in one case to the extent of twenty tons; in only three cases had its use been discontinued. All agree in reporting that the meat was in good condition as to preservation, an exceedingly small percentage of the tins being defective. With only three exceptions, it is uniformly considered to be economical as compared with the use of fresh meat; in one case the saving is estimated at £30 weekly, it being used alternately with English meat. The general average of economy in its use is variously estimated, ranging between 45 and 12 per cent., with an average of 25 per cent. As to the great importance of this source of supply, it may be sufficient to note that, while in 1866 the total quantity imported into the country amounted only to 16,050 lbs., valued at £321, in 1871 this had so enormously increased as to amount to 22,000,000 lbs., at a value of £550,000.

The Central Criminal Asylum at Dundrum.

WE understand that, as might be anticipated, very many candidates are in the field for the office of resident Medical superintendent of the Dundrum Criminal Lunatic Asylum. If our information be correct, Dr. Joseph Hatchell, resident superintendent of the Maryboro' Asylum, Sir William Carroll, and Dr. McCabe, of Waterford, are active candidates. The appointment is an exceptionally desirable one, for a large proportion of the patients are only insane in the eye of the law, and are not to be classed with dangerous or troublesome lunatics. Moreover, the resident Medical superintendent is to a certain extent his own master, there being no board of control special to the institution. The salary commences, as the Irish Medical Directory informs us, at £240, increasing from year to year to £400. The collateral advantages, exclusive of residence, coals, light, and washing, are valued at £24 16s. 7d. a year, and as the asylum is nicely situated within easy reach of Dublin the office now vacant is regarded as a particularly good appointment. Out of 187 patients on the 30th December, 1870, 31 were sane and 25 more considered to be curable.

Meeting of Medical Editors in America.

THE Third Anniversary of the Medical Editors of the United States was held in Philadelphia on the 6th of May. The President, Dr. B. F. Dawson, occupied the chair. A resolution was passed offering a prize of \$100 for the best essay on some subject to be selected at each annual meeting, and competed for by all Medical editors. The President's Address was on the "Origin of Medical Science." The officers selected for the year: President, Dr. Theoph. Parvin, of the *American Practitioner*; Vice-President, Dr. Alexander J. Stone, *N. W. Medical and Surgical Reporter*; Secretary, Dr. F. H. Davis, *Medical Examiner*.

Conversazione of the Royal College of Physicians, London.

ON Saturday evening last a conversazione of a more than usually interesting character was held at the Royal College of Physicians. Dr. Burrows, the President, had the satisfaction of receiving a crowded gathering of the notabilities of the day. Amongst the distinguished visitors we noticed the Earl of Rosse, Lord Talbot de Malahide, the Lord Mayor, Sir E. Ryan, Archbishop Manning, Lord Borthwick, Sir C. Locock, Sir W. Gull, Sir W. Fergusson, &c. The handsome and spacious rooms of the College were covered with objects of interest and beauty, and the proceedings altogether were most satisfactory.

Penrith Guardians.

THE local Government Board has issued an order closing the west ward workhouse. This will, perhaps, bring the Board to their senses. It became impossible to tolerate any longer their feeble resistance and unjustifiable procrastination.

THE American Medical Association held its annual meeting in Philadelphia, commencing on May 7th, 1872. It was perhaps the largest, and certainly one of the most cordial and harmonious meetings that have been held since the first preliminary meeting in 1846. It is stated that over 700 delegates and members were present, representing very generally all parts of the Union, from the Atlantic to the Pacific, and from the great Lakes to the Gulf of Mexico. The grand Hall of the Horticultural Building on Broad Street was occupied, but proved a very bad one to hear or transact business in, and on the morning of the second day the general meeting of the Association was moved, as the *Chicago Medical Examiner* naively informs us, into a church near at hand, which proved so much more comfortable that it continued to be occupied until the close of the session. During the first morning session a large number of reports and papers were announced and referred to the appropriate sections, and the President, Dr. D. W. Yandell, of Kentucky, delivered his annual address.

THE Select Committee on Habitual Drunkards recommends—That sanatoria, or reformatories should be provided for those who, "notwithstanding the plainest considerations of health, interest, and duty, are given over to intemperance, so as to render them unable to control themselves, and incapable of managing their own affairs, or such as to render them in any way dangerous to themselves or others."

DR. JOSEPH R. BECK, in the *St. Louis Medical Journal*, gives a summary of all the cases he has read of in which hydrate of chloral was used in traumatic tetanus. The following table shows the results :—

No.	REPORTED BY	MODE OF TREATMENT.	Whole No.	Died.	Recovered.
1	W. B. Cluness ...	Chloral alone ...	1		1
2	M. Verneuil ...	Chloral alone ...	1		1
3	{ MM. Dubrenil, La- vaux, and Onimus.	Chloral and con- tinuous current }	2		2
4					
5	Dr. Dufour ...	Chloral alone ...	1		1
6	M. Guyon ...	Chloral alone ...	1	1	
7	M. Le Fort ...	Chloral alone ...	1	1	
8	Mr. Tay ...	Chloral alone ...	1	1	
9	E. R. Denton ...	Chloral, belladonna, and potas. bromid.	1		1
10	Thomas G. Duncan,	Chloral and Calabar bean ...	1		1
11	Preston, Peter ...	Chloral and Calabar bean ...	1	1	
12	John W. Ogle ...	Chloral, belladonna and ice to spine ...	1		1
13	Mr. Croft ...	Chloral alone ...	1		1
14	Mr. Paget ...	Chloral alone ...	1	1	
15	J. Suydam Knox ...	Chloral alone ...	1		1
16 to 22	C. Macnamara ...	Chloral alone ...	7	6	1

	My own case. ...	Chloral alone ...	1		1
Totals ...			36	15	21

7th. That chloroform, up to this time has yielded the largest percentage of cures in acute tetanus.

8th. The true test of a remedy for tetanus is its influence on the history of the disease. (a) Does it cure cases in which the disease has set in previous to the ninth day? (b) Does it fail in cases whose duration exceeds fourteen days?

9th. That no agent tried by these tests has yet established its claims as a true remedy for tetanus.

AN offer of £50 has been made by a gentleman through the medium of a contemporary, to any one who can find out a cure for "hydrophobia."

THE annual meeting of the Medico-Psychological Association will be held on Wednesday, July 31st, at Edinburgh, Sir James Coxe, M.D., presiding on the occasion.

AN examination of assistant-surgeons in the Royal Navy who are eligible and who may be desirous of qualifying themselves for the rank of surgeon, will be held at the Royal Naval Hospitals at Haslar and Plymouth on Tuesday, the 16th July.

At the Stafford police-court, last week, Joseph Chattoe, shoe manufacturer, was, in default of paying a fine of £6 11s., committed to gaol for five months, for refusing to have his children vaccinated. Small-pox is very prevalent at Stafford.

THE mortality in London and twenty other large towns during the week ending June 22nd was at the rate of 22 deaths annually to every 1,000 of the estimated population. The births and deaths were below the average for the corresponding period of the last ten years.

THE New Sydenham Society has purchased the copyright of Dr. Mayne's dictionary. A small staff of editors will be appointed to undertake the task of revision and supplement, and the Profession is invited to co-operate in furnishing suggestions, emendations, or additions.

THE Anniversary Session of the St. Andrew's Medical Graduates' Association will be held at Willis's Rooms on July 6th, at 4 p.m. The President, Insp.-Gen. Gordon, C.B., will deliver the Anniversary Address, "The Army Surgeon: his Work and Works," at 5 p.m. The dinner will be at 6.15 p.m.

WE are glad to understand that the progress of Dr. Rawdon MacNamara, of Dublin, towards health is decided, though slow. Dr. MacNamara has had several temporary checks in his recovery, and his progress has not been as rapid as was hoped for, but we have reason to feel a happy confidence that we shall shortly be able to record his complete convalescence.

In the *Berliner Wochenschrift* in 1870 Dr. O. Liebreich stated that while different surgeons had made trial of the curative value of the hydrate of chloral in cases of trismus, without any favourable result he had in some cases, by the use of 3.5 grammes of the article, succeeded in causing an entire relaxation of the affected muscles. Dr. Liebreich considered that chloral does not act by removing the cause of tetanus, but simply by counteracting its effects, and that its use must therefore be persisted in so long as the muscular spasm continues to recur.

Dr. D. W. Yandell, the president of the American Medical Association arrives at the following conclusions :—

1st. That traumatic tetanus occurs in males in the proportion of four to one, and tends to recovery oftener in females.

2nd. That tetanus is most fatal in persons under ten years of age; that it is least fatal between ten and twenty.

3rd. That traumatic tetanus usually supervenes between four and nine days after the injury, and these cases represent the largest mortality.

4th. Recoveries from traumatic tetanus have been usually in cases in which the disease occurs subsequent to nine days after the injury.

5th. When the symptoms last fourteen days recovery is the rule and death the exception, *apparently independent of the treatment.*

6th. Of all the forms of tetanus, that appearing in the puerperal state is the most fatal.

THE University of Durham, at the meeting of Convocation on June 25th, elected Dr. Philipson, of Newcastle-upon-Tyne, as the representative of medicine, and Dr. Heath, of Newcastle-upon-Tyne, as the representative of surgery, on the Committee of Reference under the proposed scheme for a Conjoint Examination for England.

SCOTLAND.

EDINBURGH.

MRS. BELL.—An appeal is being made on behalf of Mrs. Henrietta Mary Bell, widow of the late James Bell, Surgeon, formerly of Amoy, China, and latterly Physician and Justice of the Peace in Port Albert, New Zealand. Mrs. Bell has been left a widow with eight children, the eldest of whom is eleven years old, and their only means of support is £16 per annum, derived from property in New Zealand, left by her late husband. Mr. Bell was educated in Edinburgh, and during his College career associated much with the students of the Edinburgh Medical Missionary Society, was favourably known to many of its Directors, and was instrumental in promoting the interests of the dispensary connected with that Society. In 1857, after having taken his diploma, he assisted Dr. Hirschberg, Medical Missionary at Amoy. He was afterwards in practice in Devonshire, whence he emigrated to New Zealand, where he continued to reside till his death, in August, 1870, after two days' illness; and by the discharge of his duties as a Medical man, a magistrate, and coroner, he won the entire respect and affection of all those with whom he came in contact. Mrs. Bell, in consequence of depreciation in the value of lands and stock, was obliged to abandon her intention of remaining in New Zealand; and, after realizing her husband's estate, it was found that there would not be a larger sum at present than £16 a year for her own and her family's maintenance. It is hoped that at least £1,000 may be raised for Mrs. Bell and her children.

DR. ARTHUR GAMGEE, Examiner in Medical Jurisprudence, London University, Dr. P. A. Simpson, Lecturer on Medical Jurisprudence, Anderson's University, and Dr. St. Clair Gray, are candidates for the chair of Medical Jurisprudence in the University of Glasgow. The appointment is in the gift of the Crown.

Literature.

ON FOOD. (a)

THE first edition of Dr. Letheby's lectures has been out of print for a long time, and was moreover disfigured, and its value to a great extent destroyed, by a number of errata in the tables. In the meanwhile, if a student or a medical man in practice enquired for a trusty hand book on the subject of food, we could only refer our querist to "a deal of confused good feeding" on the subject of food and its preparations and adulterations, scattered about in physiological works, in reviews, and blue-books, and isolated papers and lectures in various Medical Journals, there being no compendious treatise in our own language to which we could refer him. The result has not unnaturally been, that a host of men, deterred from the investigation by the enormous loss of time involved in the search for knowledge, have gone into practice with the most meagre notions on the subject of diet. Indeed, the famous Mr.

Banting, whose case is given at some length in page 123 of the work before us), said that he had consulted a great number of Medical men without even getting a rational prescription, or the least benefit, before he was fortunate enough to get better advice.

There can be no excuse for this want of knowledge now. The present edition of Dr. Letheby's lectures is practically a new book, the tables have been all revised, and some of them re-calculated, and the whole book may be regarded as a very fair *résumé* of all that is known upon the subject.

Besides all the matter in the text, there are some thirty tables, of the nutritive value and constituents of various kinds of food, which contain many hundreds of figures, and our marvel is how the publishers can produce the book at the price, for it is very nicely printed, and neatly bound in cloth. Dr. Letheby in this matter, has inherited the mantle of his predecessor Pereira, but a very slight comparison of the two treatises will show how much real progress has been made since the days when the latter published his treatise on food. The London Hospital Medical College may indeed be congratulated, that it has thus twice taken a foremost place in practical physiology. Those who know Dr. Letheby as a lecturer, will not be surprised to find that the book, though treating much of *dry* nitrogenized and other diets, is far from being a dry book, in fact it is eminently readable.

We cannot resist making two or three extracts. Speaking of the supply of food in the metropolis, Dr. Letheby says (p. 45):—"At the present time over three millions of people have to be fed daily, and yet so regular is the supply, that no one considers even the possibility of its failing. On the other hand, there is no redundancy; and not only does this supply regularly reach the metropolis, but it is distributed to our very doors. About 300 tons of fish; over 4,000 sheep; nearly 700 oxen; about 90 calves; 400 pigs (including bacon and hams); not less than 5,000 fowls, and other kinds of poultry; besides a million or so of oysters; and eggs innumerable; with flour enough to make nearly a million quarter loaves; and vegetables, butter, and beer in proportion, are daily brought to this city."—P. 45. Again, in speaking of special dietaries, he says:—"As in training the object is to form muscular tissue, with great endurance of action, and at the same time to reduce the weight of the body, it is accomplished by the use of nitrogenous food, with but little fat or farinaceous matter, and as little fluid as possible, so that muscular tissue may take the place of fat and water, and by constant exercise the endurance and strength of the muscular tissue is increased, and the proportion of water in the tissues is diminished. King, in training, is said to have taken for his breakfast two lean mutton chops, and a single cup of tea, without sugar; for dinner, 1 lb. of beef or mutton, with toast or stale bread, and very little potato or other vegetable, and half a pint of old ale, or a glass or two of sherry; for tea, a single cup of unsweetened tea, with an egg and some dry toast; and for supper, half a pint of oatmeal porridge, or half a pint of old ale." After commenting on the ill effects of a prolonged use of such a system, he continues:—"Foremost among the foods for developing fatty tissue are fats, as fat of meat, butter, milk, cream, &c., next to these are sugar and all sweet substances, as honey, saccharine fruits, parsnips, &c., and after these are farinaceous matters, as arrowroot, bread, potato, pastry, farinaceous puddings, &c."—Pp. 120, 121.

Dr. Letheby attributes more tissue forming and invigorating effects to fermented liquors than total abstainers are willing to allow, whilst at the same time he is almost eloquent in the praise of tea and coffee, and their congeners.

The following, from pages 105-6, will give a fair idea of the scientific part of the book:—

"In a general way it may be said that a healthy vigorous man consumes from 700 to 750 pounds of solid food (dry) in a year. This amounts to about 2 lbs. of dry solid matter daily, and the quantity of water (free and combined) is about 5½ lbs. daily.

Pursuing the inquiry a little farther, we find that a man

(a) "On Food: its Varieties, Chemical Constitution, Nutritive Value, &c., &c. being the substance of Four Cator Lectures." By H. Letheby, M.B., M.A., Ph.D., &c., Professor of Chemistry in the College of the London Hospital, and Medical Officer of Health and Food Analyst for the City of London. Second edition, enlarged and improved. London: Baillière, Tindall, and Cox. 1872. Pp. 335.

cannot live on a punishment-prison diet of 1 lb. of bread a day with water, for in three days he will lose about 3 lbs. in weight, and will show signs of commencing starvation. This diet contains 1·3 ozs. of nitrogenous matter and 8·8 of carbonaceous (= 1·975 grains of carbon, and 88 of nitrogen). Even the poor needlewomen of London can only just exist in a state of feeble vitality, with an average diet of 1½ lbs. of bread a day, with about 1 oz. of dripping. This contains nearly 2 ozs. of nitrogenous matter, and 14·7 carbonaceous, calculated as starch (= 3·366 grains of carbon, and 132 of nitrogen). And in military prisons where as much as 3·8 ozs. of nitrogenous food, and 22·2 ozs. of carbonaceous (= 5,090 grains of carbon, and 256 of nitrogen) are supplied daily to prisoners for short terms of confinement, they frequently lose weight, and give evidence of decay; so that for longer periods of imprisonment it is found necessary to increase the diet to 4·7 ozs. of plastic matter, and 27·8 of respiratory (= 6,362 grains of carbon, and 317 of nitrogen); in fact, according to Dr. Christison, the men confined in the prison at Perth cannot even do the work of pumping the water for the prison on a daily diet of 6 ozs. of plastic matter, and 25 of respiratory (= 6,082 grains of carbon, and 404 of nitrogen).

During the siege of Paris, when provisions were almost exhausted, it is said that the daily rations were reduced to 300 grammes (4,629 grains of bread, and 30 grammes (436 grains) of meat per head daily—the bread being composed of 30 parts wheat, 30 rice, 20 rye, and 20 oats. This is in the proportion of only 1·44 ozs. of nitrogenous matter (= 94 grains of nitrogen), and 10·01 ozs. of dry carbonaceous matter, calculated as starch (= 2,234 grains of carbon) daily. It is not possible, however, to maintain life on such a diet. Earlier in the siege when the French Government became anxious about the food supply, they consulted the leading physicians of Paris on the subject, and Dr. Sée was instructed to lecture on it at the School of Medicine. He said that the daily diet of an adult might be made up as follows:—100 grammes (= 1,543·2 grains) of beef; 20 grammes (= 308·6 grains) of salt fish; 750 grammes (= 11,574·3 grains) of bread; 50 grammes (= 771·6 grains) of bacon, and 50 grammes of vegetables. These contain 3·14 ozs. of dry nitrogenous matter (= 235 grains of nitrogen), and 18·53 ozs. of carbonaceous, calculated as starch (= 4,241 grains of carbon); but these proportions are hardly sufficient to maintain life, even when the body is performing no work beyond its own physiological movements.

Dr. Edward Smith found in his inquiries into the dietaries of adult male operatives of Lancashire and Cheshire during the cotton-famine, and also into those of the low-fed operatives of England, that the daily amount of food only barely sufficient for existence, must contain 2·84 ozs. of nitrogenous matter, and 19·25 of carbonaceous (= 4,321 grains of carbon, and 191 of nitrogen). These are contained in 2 lbs. 4 ozs. of bread, which is regarded as a famine diet. The farm labourers of England consume daily an average of 3·18 ozs. of plastic matter, and 26·01 of respiratory. In Scotland, Wales, and Ireland, the amounts are somewhat larger."

At a time when butcher's meat is so dear, the following description of good meat is at least seasonable:—

"1st. It is neither of a pale pink, nor of a deep purple tint, for the former is a sign of disease, and the latter indicates that the animal has not been slaughtered, but has died with the blood in it, or has suffered from acute fever.

"2nd. It has a marbled appearance, from the ramification of little veins of fat among the muscles.

"3rd. It should be firm and elastic to the touch, and should scarcely moisten the fingers—bad meat being wet, and sodden and flabby, with the fat looking like jelly or fat parchment.

"4th. It should have little or no odour, and the odour should not be disagreeable, for diseased meat has a sickly cadaverous smell, and sometimes a smell of phos. This is very discoverable when the meat is chopped up and drenched with warm water.

"5th. It should not run to water, or become very wet on standing for a day or so, but should, on the contrary, dry on the surface.

"6th. When dried at a temperature of 212° or thereabout, it should not lose more than from 70 to 74 per cent. of its weight; whereas, bad meat will often lose as much as 80 per cent.

"7th. It should not shrink or waste much in cooking.

"Other properties of a more refined character will also serve for the recognition of bad meat, as that the juice of the flesh is alkaline or neutral to test paper, instead of being distinctly acid, and the muscular fibre, when examined under the microscope, is found to be sodden, or ill-defined." Pp. 210-11.

The author also points out that the microscope is necessary to the diagnosis of some parasitic forms of disease met with in meat—there is a good description of the trichina disease—and of the chief methods of cooking and preserving various articles of food. And there is also a capital statement of the physiological requirements of the body, and the mode of calculating the true nutrient value of foods.

The subject of prison diets is also carefully considered, and Dr. Letheby appears to attribute some of the violent outbreaks amongst our convicts to *over-feeding*, whilst (as may be expected) he deems our workhouse poor decidedly *under-fed*. We confidently predict for this book an enormous sale, and the only suggestion we would make to the learned author for its improvement, is to place the tables (except the very short ones) in an appendix at the end, for those who really care for them would then and them more easily, and this would improve the appearance of the book.

INTRODUCTION TO THE STUDY OF BIOLOGY (a).

PROFESSOR NICHOLSON and his works have both attained that happy eminence which renders them independent of the praise or blame of contemporary criticism. But in spite of such success, or, perhaps, we should say for that very reason, the reviewer has a twofold duty to perform—first, to his readers, to keep them well apprised of the state of the literary market—what there is of new—how much of that is good—and what to "eat, drink, and avoid" in the bibliophagist's sense; for even the best and most scholarly of authors are a little apt to serve us up dishes of hashed meats, *à la Cumming*, and some publishers are fond of "new editions," when the only alterations are a new preface and title page, or the correction of an erratum or two in the index: and, secondly, to the authors themselves, for there is an intoxication in success, especially in literature, which often makes a man oblivious of those *petits soins* which not seldom make or mar a book. Happily, in the case before us our duties are light and pleasant. We have scarcely a word, save of praise, for the little volume before us. The publishers (as we might expect from their firm) have produced a tasteful, remarkably well-printed, and well-illustrated volume. Although it is admitted to be founded upon a chapter in one of the author's former works, there is so much new matter in it, and the old has been so thoroughly revised and re-written, that it really is, to all intents and purposes, a new book. Dr. Nicholson calls it an "Introduction," although, for our part, we think that the earnest student would do best to read it *after* he has mastered, or at all events, thoroughly read the author's text-book of Zoology. Nowhere else, we believe, can the student, whether he be the theologian anxious to learn the set of the tide and the direction of the under-current of thought of modern science and philosophy—the man of letters—or the medical student—or, lastly, the practitioner who is not quite ignorant of the elements of comparative anatomy, but is slightly puzzled with such new terms as Homogeny and Homoplasia, Abiogenesis and Bioplasm; nowhere else, we believe, can these meet with such clear definitions, and with such fair expositions of rival theories as in the pages before us. The note on page 123, and

(a) "Introduction to the Study of Biology." By H. Allyn Nicholson, M.D., D.Sc., M.A., Ph.D., F.R.S.E., F.G.S., &c., Professor of Natural History and Botany in University College, Toronto; formerly Lecturer on Natural History in the Medical School of Edinburgh, &c., &c. Wm. Blackwood and Sons, Edinburgh and London. 1872. Pp. 168.

the frequent references to modern experiments on the (alleged) spontaneous generation in infusions, show how thoroughly the author is up to time in his subjects. Nor is botany ignored, as too often happens (even on the Isis), although we think still more use might be made of it; and we utterly fail to see the use of the very meagre classification of plants on page 42. To the botanist it is superfluous, to the tyro it is unintelligible, unless it had been illustrated as the animal classification is. The chemical portion of the work is, however, the weakest portion of it, and we should strongly advise this to be entirely rewritten. It is sketchy, abounds in repetitions, is not always accurate, adopts the almost obsolete old notation in the only two instances of formulæ given, and, strangely enough, these (of starch and albumen) are, although *not* the most usual formulæ, given without a hint that they are not universally accepted. One more little carp, and we have done with a fault-finding which really springs from our love of the book. Why should the author use the word *inconceivable* on page 10, line 19? Has he ever read Frankenstein? Surely he means *improbable* in the highest degree. But these are all such minor blemishes that they do not really detract from the merits of this eminently readable, scholarly, and philosophic book.

NEW EDITION OF MALTHUS ON POPULATION (a).

(Notice by C. R. DRYSDALE, M.D., M.R.C.P. Lond., F.R.C.S. Eng.)

(Continued.)

HE continues: "From the accounts we have of China and Japan, it may be fairly doubted, whether the best directed efforts of human industry could double the produce of these countries even once in any number of years. There are many parts of the globe indeed, hitherto uncultivated, and almost unoccupied, but the right of exterminating, or driving into a corner where they must starve, even the inhabitants of these thinly peopled regions, will be questioned in a moral point of view. The process of improving their minds, and directing their industry would necessarily be slow; and during this time, as population would regularly keep pace with the increasing produce, it would rarely happen that a great degree of knowledge and industry would have to operate at once upon rich unappropriated soil. Even where this might take place, as it does sometimes in new colonies, a geometrical ratio increases with such extraordinary rapidity, that the advantage could not last long. If America continue increasing, which she certainly will do, though not with the same rapidity as formerly, the Indians will be driven further and further back into the country, till the whole race is ultimately exterminated."

How true a prophecy this has been of a writer writing in 1806, we of 1872 know well. America has now forty millions in the United States alone, and the poor Indians are gradually disappearing in the struggle for existence.

Mr. Malthus goes on to say, "Europe is by no means so fully peopled as it might be. In Europe, there is the fairest chance that human industry may receive its best direction. The science of agriculture has been much studied in England and Scotland, and there is still a great portion of uncultivated land in these countries. Let us consider, at what rate the produce of this island might be supposed to increase under circumstances the most favourable to improvement. If it be allowed that by the best possible policy, and great encouragement to agriculture, the average produce of this island could be doubled in the first twenty-five years, it will be allowing probably a

greater increase than could with reason be expected. In the next twenty-five years, it is impossible to suppose that the produce could be quadrupled. It would be contrary to all our knowledge of the properties of land. The improvement of the barren parts would be a work of time and labour, and it must be evident to those who have the slightest acquaintance with agricultural subjects, that in proportion as cultivation extended, the addition that could yearly be made to the former average produce must be gradually and regularly diminishing. That we may be the better able to compare the increase of population and food, let us make a supposition, which, without pretending to accuracy, is clearly more favourable to the power of production of the earth, than any experience we have had of its qualities will warrant. Let us suppose that the yearly additions which might be made to the former average produce, instead of decreasing, which they certainly would do, were to remain the same, and that the produce of this island might be increased every twenty-five years by a quantity equal to what it at present produces. The most enthusiastic speculator cannot suppose a greater increase than this. In a few centuries it would make every acre of land in the island like a garden."

He then illustrates the contrast between the "Law of Population" and the "Law of Agricultural increase," as follows: "Let us call the population of this island eleven millions (1806), and suppose the present produce equal to the easy support of such a number. In the first twenty-five years, the population would be twenty-two millions, and the food also being doubled, the means of subsistence would be equal to this increase. In the next twenty-five years the population would (tend to), be forty-four millions, and the mean of subsistence only equal to the support of thirty-three millions."

Mr. Malthus gives the checks to population existing among the American Indians, South Sea Islanders, in Africa, Siberia, Turkey and Persia, Hindostan, and Thibet. He also speaks of the checks to population in China and Japan, and gives a learned account of the checks which existed in Greece and Rome. Norway, Sweden, Russia, Germany, Switzerland, France, England and Scotland, are then spoken of, and then come general reasonings on the fruitfulness of marriages and the effects of epidemics. The rest of the work is taken up with essays on Godwin's views, on Emigration, Poor-laws, and other topics of social economy. Book IV. the last, speaks of moral restraint or late marriage, Mr. Malthus's hope for the future of the race, and of the abolition of those dangerous poor-laws, which existed in his day.

We have not space to touch on any of these most interesting chapters. Suffice for us if we have made our readers determined to consult this fountain-head of the literature of this branch of sociology. We cannot, indeed, agree with Mr. Malthus's ideal of late marriage as a cure for the evils of over-population. The sufferings caused by late marriages are terrible to both sexes, but especially to the better educated of the female sex, and moreover, late marriages are one cause of prostitution and of the great prevalence of syphilis in our midst. Emigration, too, was held by the great Chalmers, as a delusion and a snare to any nation that relies on it to lessen the poverty of those of its people who remain at home.

Correspondence.

THE GRIEVANCES OF POOR-LAW MEDICAL OFFICERS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I thought from the tone of the writing in the MEDICAL PRESS AND CIRCULAR of last year, respecting the Poor-law Medical officers forming a Club in cases of disability through age or otherwise, as the case may be, that some definite step would have been taken ere this; and further, it

(a) "An Essay on the Principle of Population; or a View of its Past and Present Effects on Human Happiness, with an Inquiry into our Prospects respecting the Future Removal, or Mitigation of the Evils which it Occasions." By the Rev. T. R. Malthus, A.M., F.R.S., late Fellow of Jesus College, Cambridge, and Professor of History and Political Economy in the East India College, Hertfordshire. Seventh Edition. London: Reeves and Turner. One vol octavo, 1872.

was finally reported that the Superannuation Act would assist those gentlemen who had served for twenty years and upwards in two district unions. Now, the Poor-law Board have been applied to in this matter, and they rather inclined to recognise only such service as shall have been given solely in one union. This seems hard indeed if such should in reality be acted upon; and, besides, it appears to me that the Poor-law Superannuation Act is a complete *failure*. And how is it? Simply that the guardians have the power of doing as they please at their own *discretion*. Look, for instance, at the recent case of Dr. Grubb, Poor-law Medical Officer of a district in the Warminster Union for at least upwards of twenty-five years; he made application to the guardians for superannuation, and they declined it *in toto*. It so startled some of his friends in the neighbourhood that they immediately set to work, and made a collection for him in the locality, and in two or three days sent him a cheque for £200. This looked like putting the shoulder to the wheel in earnest; but it should be understood that the guardians in some unions have acted liberally in the extreme, by granting superannuation to those whom age or disability has rendered it necessary for them to make such a claim. And, again, I must not omit to state that, although talked about, there has been a re-adjustment of salaries in but few of the unions, which ought to have been general, without favour or otherwise. Look at the price of necessaries of food and fodder of every kind, and contrast it now and twenty years ago—even drugs are nearly doubled. All this ought to be taken into due consideration, and no reasonable or well-informed man will say but what has been herein stated is perfectly correct, and need be remedied. As the Poor-law Board have power to remedy these evils, they should put it in force, and not degrade the Profession, but elevate it to a proper standard, in accordance with the times in which we live. I trust you will continue, with the aid of your powerful Journal, to assist in carrying out those suggestions in a way suitable to the general feeling of that hard-worked and badly-remunerated body—

THE POOR-LAW MEDICAL OFFICERS.

Barnstaple.

P.S.—It ought not to be omitted that the population is more than doubled since the Poor-law Board was formed; and disease, it may be said, is more virulent in its *form*! I should state about forty unions joined in petitioning a favour of the superannuation fund.

CORONERS' MEDICAL WITNESSES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In a recent number of your paper a correspondent gives his experience of a coroner and his treatment of Medical witnesses. With your permission I will relate a similar case; but of the two I think mine is the worst. The coroner in my case was a solicitor.

Very late one stormy evening I was asked to see an old man who had been found lying on the railway, and was supposed to be dead or dying. I attended at once. Upon my arrival, I found he was dead; and from external appearances he seemed to have been struck by a locomotive, and from the injuries I have no doubt was killed instantaneously. I explained to the friends of the deceased the injuries he had sustained, and also my opinion that death was immediate. I was requested by the police to attend the inquest, which I did. One of the men who had found the deceased was a witness also; and in reply to a question of the coroner as to where he was injured, detailed to him every word I had said at the time I saw the body,—viz., there was fracture of the skull, dislocation of the cervical vertebra, &c. The man gave a description of the injuries almost as well as I could have done myself, and used nearly the same words that I did when I described the injuries to the friends of the deceased. After this witness was done, the coroner asked if there was any more evidence; and when he was told there was the doctor, he said, "No; after the last evidence I don't require that of a surgeon."

Parley was useless, so I at once left the room. My reward for travelling two miles on a stormy night and afterwards attending the inquest was *nil*.

I am, yours faithfully,

WILLIAM EASBY,

Northgate, Darlington,

F.R.C.P. Edin.

THE TITLE OF DOCTOR.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The question which your correspondent raises as to the right of all qualified Medical practitioners to the courtesy prefix of Dr. has been so ably discussed in the leading articles of the *Doctor*, Vol. I., Nos. 3 and 10, that I must refer your readers to that publication, to the arguments of which I have nothing to add. With regard to my philanthropy, I do not claim any. I have the misfortune to reside in a neighbourhood infested with venereal quacks, and I have taken upon myself the trouble and expense of prosecuting one of the most conspicuous, with the object of testing the legality of one of the sham diplomas which the Medical Council has thought fit to place on the *Medical Register*. The Magistrate has decided that these purchasable diplomas are of no more value than waste paper, but Hamilton, who possesses one, has availed himself of his right to appeal against the magistrate's conviction.

Now, Sir, I have resolved that unless the Profession, the Medical Council, or some one else will provide funds and assist me to retain counsel to support the magistrate's conviction, this case must drop, as I think I have done as much as can be expected of a private individual. So the quacks will henceforth know that they can purchase a diploma, carry on the practice of a Medical man, rob the public, and defy the law; it will be much cheaper for them, and far less trouble, than studying and passing examinations. I am afraid I have done a fine stroke of business for the diploma vendors, who will now advertise largely, and quote Hamilton's prosecution to prove that their customers have nothing to fear.

I remain, Sir, your obedient servant,

HENRY P. CHANDLER, M.R.C.S.

66 Berners Street, London, W., July 1st.

Obituary.

WILLIAM TEMPLE, OF MONAGHAN.

THIS week is marked by the death of one of the best and most revered of the old school of provincial practitioners in Ireland, who, in his green old age of eighty-two, has passed from the ranks of the Profession, to which during nearly sixty years of practice he did nothing but honour. The rôle of a Workhouse Medical Officer is not one in which honour and notoriety can be rapidly accumulated; yet there are few men in the locality in which Dr. Temple had carried on his practice who could be less easily spared, or whose death would be more universally regretted. The *Monaghan Standard* says:—

"Dr. Temple's private practice was extensive. His uniform geniality of disposition won the friendship of those with whom his professional avocations brought him in contact. In 1817 he first commenced practice in this town, having been appointed in that year Medical attendant to the Fever Hospital; and we believe we are correct in stating that since that period until within a few weeks of his death he diligently performed the duties of his several appointments almost without intermission. Naturally possessed of a vigorous constitution, conserved by regular habits, he was capable of, and did endure, without exhaustion, an amount of labour that to others would be oppressive. Thus it need not be a matter of surprise that at the age of eighty-two years he was still found in possession of those fine faculties by which all through life he had been distinguished. To this community it is superfluous to recapitulate his many fine qualities, or dwell on the deep sorrow with which the announcement of his death has been received. We all recognised in him a skilful physician, an honourable gentleman, a good citizen, a true friend, and a most charitable and benevolent Christian."

Medical News.

Royal College of Surgeons of England.—The following candidates having passed the required examinations, received their diplomas in dental surgery, at a meeting of the Board of Examiners, on the 25th ult.: viz., Messrs. Leighton Baylis, of Cheltenham; James Oakley Coles, of Wimpole Street, Cavendish Square; William Edward Harding, of Stafford; Samuel John Hutchinson, of Manchester; and William Lloyd Poundall, of Derby.

Conversazione at the Royal College of Physicians.—Last Saturday evening the College of Physicians gave its usual annual soirée, which was numerously attended by a learned and chosen body of scientific men. Among the curious objects exhibited, we noticed an admirable preparation of the cornea of a frog by Mr. Jabez Hogg, wherein the nerves of the cornea were clearly demonstrated. The cornea had been steeped in chloride of gold, and was viewed by an object glass magnifying about 180 diameters. Messrs. Powell and Lealand exhibited two object glasses of 1-50th and 1-80th in focus. Dr. John Ogle showed some curiosities from the Swiss lakes. Wine and ices were served as refreshments, and this year the hats and coats were put away in a sensible manner; but, on the whole, the soirée of the Pharmaceutical Society, which took place in the South Kensington Museum, was more agreeable, and we should counsel the Physicians to hold their conversaciones also there, and to invite ladies occasionally. Tea, ices, and coffee are much more wholesome than bad wine, and cheaper; and music is an agreeable feature of a conversazione which might occasionally be introduced. Ought there not to be a short lecture on some scientific subject at such conversaciones?

The Public Health Bill.—In the House of Commons on Friday, in reply to Mr. Rylands, Mr. Stansfeld said it was unquestionably the intention of the Government to proceed with the Public Health Bill. The Bill was committed *pro forma* last evening for the insertion of certain amendments. He had unwillingly come to the conclusion that, considering the advanced period of the session and the pressure of public business, it was necessary, in the interest of the Bill itself, to do what was sometimes called throwing part of the cargo overboard. He had examined the Bill in order to see what sacrifices it was necessary to make in order to ensure the passing of the Bill. The House would remember that last year they consolidated certain departments of the measure with the Central Government Bill. The Bill as it stood might be divided into three parts, one consisting of provisions organising the local sanitary authorities, followed by the body of the Bill giving new powers to and imposing new duties upon those authorities; and then came a number of miscellaneous clauses, giving facilities for the proceedings of the local authorities. It appeared to him that the best course would be to stop this year with the creation and consolidation of the local authorities, and to withdraw from the Bill all the clauses relating to nuisances, hospital, river pollution, and other matters.

Extraordinary Excitement in the Wards at Guy's Hospital.—On Sunday morning a man named Taylor was taken to Guy's Hospital, with a frightful self-inflicted gash in the throat. Having just previously murdered his wife and one child, and almost taken the life of another, it was readily seen that he was suffering under dangerous cerebral excitement, and after his own wound had been dressed, he was placed in the accident ward, under the charge of a nurse and a constable. He appears to have remained calm until about half-past seven o'clock in the morning, when he suddenly jumped out of bed in his shirt, seized the weights of the clock, and leaped from the folding windows of the ward which open to the ground on to the parapet beneath. He then rushed through the laundry yard and entered the door which led to other wards and locked the door. He then ascended to a man's ward, but did not enter there, and went on until he came to Petersham Ward, which is devoted to women in an advanced state of disease. Here he seized the tongs, and advancing to the nurse, told her that he did not wish to harm the patients, but intended to kill the nurses. The woman was so affrighted that she sprang out of the second floor window to the ground, but was, fortunately, not much hurt. Several of the patients fainted, and others who had not been out of bed for months managed to crawl out. Taylor for some

time after this paraded the different corridors until, by the united efforts of the bath men, he was, at considerable personal risk, secured and taken to the strong room, where the strait waistcoat was put on, and he now remains there in a precarious state.

Cleanings

Gangrene Produced by Dressings of Carbolic Acid.

DR. TILLAUX reports two cases in which gangrene resulted from the application of carbolic acid to wounds.

Opium as an Antidote to Belladonna.

DR. PETERFIELD TRENT reports a case of poisoning by ten grains of belladonna, in which laudanum was used with success as an antidote.—*Jour. of Materia Medica*

Perchloride of Iron in Post-Partum Hæmorrhage.

DR. J. T. JOHNSON (*National Med. Journal*) says:—“In the Dublin Practice of Midwifery, the bold advice of Dr. Robert Barnes, of London, is followed in cases of *post-partum* hæmorrhage, in the injection into the uterus of a solution of the perchloride of iron—strength, one part to four parts of water. They inject very cold water into the uterus, taking the usual precaution not to inject air, and if not successful in controlling the hæmorrhage, they then use the perchloride of iron. They are much pleased with its effect, and recommend it very strongly.”

Recurrent Vision.

PROF. A. C. YOUNG, of Dartmouth College, mentions a fact which, so far as we know, has not been noticed before. He states that on illuminating a room with an electric spark, any object that was looked at re-appeared at short intervals for two or three times. He experimented with a black screen, on which was fastened a white cross, made of strips three or four feet long by a foot in width. He is sure that the re-appearance of the object is not due to a repetition of the spark, for upon moving the screen backwards and forwards, the cross always appeared in the same place. He measured the intervals between the appearance of the object by an ingenious contrivance, and finds it to be from 0.17 to 0.30. The explanation that he gives of this phenomenon is that it is due to “a reflection of the nervous impulse at the nerve extremities—as if the intense impression upon the retina, after being the first time propagated to the brain, were then reflected, returned to the retina, and from the retina travelling again to the brain, renewed the sensation.” He calls this phenomenon “Recurrent Vision.”—*Am. Jour. Science and Arts*, April.

Pathology of Consumption.

DR. BATTSON says:—“I cannot agree with Niemeyer that the vegetarians in diet are more subject to consumption than the well-to-do, or better fed class. Something else than an excess of lime in the blood is necessary for the production of tubercle.

“Louis's fatty liver of consumptives will help us to the explanation. I regard ‘phthisis’ as much more frequently affecting the intellectual—the large-brained, the nerve temperament. I am guessing, as you may think; but it seems to me as *cholesterins* is the normal waste of brain and nerve tissue (*Reporter*), so is tubercle the morbid waste, or detritus of brain and nerve tissue. Tubercle is essentially granular, composed of aplastic or retrograde cells with nuclei enclosed. An excess of phosphorised fat, as well as an excess of lime in the blood, is absolutely essential to the production of tubercle.

“I have the very best authority for saying that the rural population of France are vegetarian in diet; and yet that population are freer from consumption than any other, except, perhaps, Italy and Spain (vegetarian) in Europe, certainly than that of Great Britain, or any part of central Europe. Our New England population are largely more subject to tuberculosis of the lungs than the population of any other part of the United States, and, although largely vegetarian, still consume more fatty diet than can be appropriated to its physiological uses. Besides, so I am told, the water used in New England for drinking purposes and cooking is soft and not limestone, as it ought to be.”—*Philadelphia Medical and Surgical Reporter*.

Dimness of Vision Following the Use of Hydrate of Chloral.

E. BURKE HAYWOOD, M.D., Raleigh, N.C. (*Rich. and Louis. Med. Jour.*), writes that he gave hydrate of chloral in twenty-grain doses for two weeks, to an old gentleman complaining of buzzing in the head, pulsation of the epigastrium, and soreness around the waist. At the expiration of two weeks the patient complained of dimness of vision, which, rapidly increasing, he suspected that this remedy caused it, and discontinued its use, when his vision improved, and gradually became as good as it was before using the hydrate of chloral.

Progressive Pernicious Anæmia

In the *Medizinische Central Zeitung*, Prof. Biemer calls attention to this invariably fatal disease. He has seen fifteen cases in five years. The patients have a hydra-anæmic appearance, loss of appetite, but not of fat, anæmic sounds in the arteries, capillary hæmorrhages, especially of the retina, often with disturbances of the sight, some fever, and progressive debility. The *post-mortems* showed fatty degeneration of the heart and muscles.

NOTICES TO CORRESPONDENTS.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this request.

All communications intended for insertion, must bear the name and address of the writer; not necessarily for publication, but as a voucher of good faith.

Rejected MS. will always be returned, if a request be received from the author, within one week after the article or letter has been declined.

SUBSCRIPTIONS.—Gentlemen who have not paid their subscriptions for 1871 and—in a few cases—previous years are respectfully reminded of the omission.

POST-MORTEM DELIVERY.—In an article upon this subject, the *Indian Medical Gazette*, received by last mail, says:—"The *MEDICAL PRESS AND CIRCULAR* of 3rd April contains two letters by D. S. Swayne, of Carrick-on-Shannon, and Lunigan, of Ballymahon, describing two instances of *post-mortem* expulsion of the foetus through the agency of gaseous distension of the abdomen. Dr. Swayne states that he 'never heard (or read of a similar instance).' We suspect that the incident is not an uncommon one in India; medico-legal practice. We can recall at least one instance of such an occurrence. The body of a pregnant female is despatched from a distant part of a district, and wrapped up rather loosely in a coarse cloth and bamboo matting. On arrival at the sudder station, the civil surgeon finds it semi-putrid, eyes bursting, limbs widely apart, and abdomen swollen and hard as a drum. On removing the coverings, a foetus is found between the thighs, and the uterus not unfrequently prolapsed, while the bystanders declare that when the body was started, nothing of the kind was observed." Those of our readers who have seen or may see similar cases, would confer a benefit by forwarding a short account of them.

MR. R. DAWSON.—"The Tancred Trust Fund" is, we believe, a charity exclusively for the clergy of the Church of England. There is a little work entitled "Clergy Charities" which will probably give you all the information you require.

MR. H. E. R.—The work is of American origin, and was published in 1863. It is looked upon as an authority across the Channel, but we have not often met it in this country. You could doubtless obtain a copy through Baillière, Trübner, or other of the foreign houses in London.

DR. WILLIAMS.—Yes; Dr. Anstie.

VACANCIES.

St. Mary's Hospital, Paddington. The office of Assistant Physician, and that of Assistant Physician Accoucheur. Both Honorary.

St. Pancras Dispensary, London. Physicians. Honorary.

Brompton Consumption Hospital. Dental Surgeon.

Western Dispensary, Marylebone. Resident Surgeon. Salary £100.

Leads Dispensary. Junior Resident Medical Officer. Salary £60, with board.

Newbury Union. Medical Officer. Salary £140, fees extra.

Salford Hospital. District Surgeon. Salary £30, with board.

Donset Lunatic Asylum. Assistant Medical Officer at Forston, and at the Charmwater branch. Salary £100 each, with board.

Ramsgate Dispensary. Resident Medical Officer. Salary £100.

Consumption Hospital, Ventnor. Resident Medical Officer.

Liverpool Royal Infirmary. Demonstration of Anatomy.

Liverpool Royal Infirmary. Lectureship on Physiology.

Athlone Union, Irwate District. Medical Officer. Salary £100.

Oughterard Union, Clontarf District. Medical Officer. Salary £100.

Hospital for Sick Children, Great Ormond Street. House-Surgeon. Salary £30 per annum, with board and residence.

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

The following Medical and Scientific journals have been received:—*Indian Medical Gazette*; *Nature*; *The Monthly Microscopical Journal*; *New York Medical Journal*; *Wiener Medizinische Zeitung*; *Canada Medical Journal*; *Boston Medical Journal*; *Canada Lancet*; *Australian Medical Journal*; *The Practitioner*; *Le Mouvement Médical*; *La France Médicale*.

APPOINTMENTS.

ALLFREY, C. H., M.D., F.R.C.S.E., Surgeon to the Asylum of the Government Institution at Chislehurst.
BAKER, E. C., L.R.C.P.L., House-Surgeon to St. George's Hospital.
BEACH, F., M.R.C.S.E., Medical Registrar to the Hospital for Sick Children, Great Ormond street.
FLOYER, Mr. B. B., Assistant House-Surgeon to the Sheffield Infirmary.
GARTON, W., M.R.C.S.E., late Resident Accoucheur, House-Surgeon at St. Thomas's Hospital.
HAMILTON, D. J., L.R.C.P.Ed., L.R.C.S.Ed., Junior House-Surgeon to the Northern Hospital, Liverpool.
LAYER, A. H., M.R.C.S., House-Physician to St. Thomas's Hospital.
HAYNES, H., M.D., Medical Superintendent of the Male side of the Middlesex Lunatic Asylum, Hanwell, has been appointed Lecturer on Psychological Medicine at the Middlesex Hospital Medical College.
RICHARDS, J. P., M.R.C.S.E., Medical Superintendent of the Female Department of the Hanwell Lunatic Asylum.
SARGANT, E., L.R.C.P.L., House-Surgeon to St. Thomas's Hospital.
SHORE, R. L., M.R.C.S.E., second Assistant Medical Officer to the Essex Lunatic Asylum, Brentwood.
SLATER, J. S., M.R.C.S.E., late House-Physician, has been appointed Resident Accoucheur at St. Thomas's Hospital.
STEWART, W., L.R.C.P.Ed., L.R.O.S.Ed., has been elected one of the Honorary Surgeons to the Beckett Dispensary and Hospital, Barnsley.
VASEY, C. L., L.R.C.P.L., M.R.C.S., House-Surgeon to the Northern Hospital, Liverpool.
VERNON, B. J., F.R.C.S., Ophthalmic Surgeon to the Great Northern Hospital.
WATERS, A. T. H., M.D., F.R.C.P.L., Lecturer on the Principles and Practice of Medicine at the Liverpool School of Medicine.

Marriages.

GRANT—KEILLER.—On the 18th June, at 21 Queen Street, Edinburgh, G. H. Grant, Esq., of Bhangulpor, Bengal, to J. M. Elizabeth, second daughter of Alex. Keiller, M.D., F.R.C.S.
HIBBERD—ADAM.—On the 27th June, at St. Paul's Presbyterian Church, Westbourne Grove, Edw. Hibberd, M.D., of Westbourne Place, Harrow Road, to Anna Bella, eldest daughter of J. Adam, Esq., of Westbourne Villas, Harrow Road.

Deaths.

CARLESS.—On the 17th June, at Long Melford, Suffolk, William Carless, M.B., C.M., eldest son of Dr. Carless, of Stratford Lodge, Stroud, aged 29.
COOPER.—On the 23rd June, at Leek, Staffordshire, Richard Cooper, L.R.Q.C.P.I., L.M., M.R.C.S.E., aged 68.
ELLIOTT.—On the 20th June, at North Street, Chichester, Robert Elliott, F.R.C.S.V., L.S.A., F.S.A., for more than thirty years surgeon to the Chichester Infirmary, aged 69.
KEMP.—On the 19th June, at Secunderabad, R. D. Kemp, M.B., C.M., Assist. Surgeon 16th Lancers.
McDONNELL.—On the 27th June, at Great Malvern, Robert McDonald, M.D., of Cheltenham, aged 55.
TRUSTRAM.—On the 25th June, at Tunbridge Wells, suddenly, Chas. Trustram, M.F.C.S.E., in his 61th year.

CLINICAL LECTURE ON A CASE OF CEREBRAL HÆMORRHAGE.

By C. HANDFIELD JONES, M.B. Cantab, F.R.S.,
Physician to St. Mary's Hospital.

D. D., æt. 65, admitted May 23, 1872. He fell down this afternoon in a fit; was insensible for a short time, but soon recovered. When brought to the hospital he was tolerably conscious, and could answer questions, though his speech was a good deal impaired. His eyes were turned strongly to the right, as if he were gazing on some object in that direction. Left arm and leg were paralysed, and there was more reflex action in left leg than in right. His face was a little drawn to right. Pupils small, equal. Some frontal headache and drowsiness. Enema, ζ . Ol. ricini; Liq. ergotæ, ζj , and Aq. ζvij ; quater die. Simple diet, milk. 24th.—Lies on his back insensible, cannot be moved, breathes rather stertorously, 26 per minute. Pulse, 74; temp, 100°. Motions and urine passed in bed. Is uneasy and restless, moving his right arm a good deal. Pupils small, heart sounds normal. Urine contains albumen. Head hot, vessels full, carotids pulsate moderately. 25th.—Remains insensible, breathing at noon 50 per minute. Pulse so quick and small as not to be counted. Countenance not livid one hour before death, which occurred at 1 p.m.

Autopsy.—Convulsions flattened, most on right side; sulci narrowed, especially at posterior part of both hemispheres. A large cavity containing about two ounces of clot and blood, of hen's-egg size, at postero-lateral side of right hemisphere, extending to near the surface; below it reached to the anterior extremity of corp. striat. and to about the lower level of this body and the Thalamus Opticus. It did not involve these ganglia at all, but they were pushed to the left, and the right ventricle greatly narrowed; the left contained some bloody serum. In the left corp. striat. there were some yellow streaks. The

third pair of nerves, and the optic, and all the structures at the base of the brain appeared normal; the rest of the encephalon also was healthy. The right mid-cerebral artery and the basilar presented some large masses of atheroma, one of these, particularly was of considerable size, and encroached on the canal of the vessel. The cerebral veins contained much blood posteriorly, anteriorly they were rather anæmic. Both lungs, especially the lower lobes, were highly engorged and inflamed. Heart, mitral valves efficient, aortic flaps thickened and calcareous, two of them fused together. Kidneys contracted and granular, right 3 oz., left 3½ oz., spleen normal.

I shall not, on the present occasion, take up your time in remarks on the pathology of cerebral hæmorrhage, with which most of you are probably pretty well acquainted; but I shall ask you to accompany me in a discussion relative to the causation and import of some of the principal symptoms. Though the topic is chiefly theoretical, it has, you will see a material relation to practice. I propose for solution the following queries:—1. Why is the patient in such a case as I have detailed to you unconscious? 2. Why does he die? Let it be remarked, *in limine*, that, as the patient was only paralysed on one side, he might be expected only to be unconscious, if I may so say, also on one side. As the basal ganglia on the right side were capable, of functioning, why should not the hemisphere on that side be capable also? But even from the first he was stuporous and soon became quite insensible. Again, I ask you to observe that at the time he was utterly comatose and near death, he was breathing fifty times per minute, so that his respiratory centres were certainly not unexcitable.

Now, the reply usually given to the above queries makes excessive pressure the sole cause; the effused blood by compressing the hemispheres is believed to render them anæmic, and so incapable of functioning, while the medulla oblongata being in a like state the nervous actions which minister to respiration and circulation are similarly arrested. That this cause is without effect I by no means assert, but that it is the sufficient and principal cause I greatly doubt. For think of choleraic cases, where, though the pulse has ceased and a mere dribble of blood is found in an opened artery, the patients have yet full possession

of their mental faculties. It can hardly be contended that the subject of cerebral hemorrhage has less circulating blood in his hemispheres than the man in choleraic collapse. In our patient, although the other viscera were examined before the brain, there was certainly no notable anæmia of the hemispheres. This consideration makes it very doubtful to my mind whether cerebral anæmia is a *vera causa*. Again, think of cases of simple apoplexy, such as Abercrombie described, and whose occurrence is attested by such accurate observers as Wilks and Hughlings Jackson. The latter says—"a patient, sometimes even a young man, quickly becomes insensible and dies in a few hours, and in the whole body we find nothing abnormal which can reasonably be supposed to have been the cause of the symptoms." Here there is no pressure and no poisoning (apparent), yet we witness profound insensibility and death by coma. Think also of cases, such as one recorded in the "Pathological Society's Transactions," Vol. XI, p. 11, where a female, æt. 66, died with a clot of blood of half walnut size almost in the middle of the pons varolii, and lay almost utterly insensible with powerless limbs and contracted insensible pupils for sixty-six hours, the time intervening between the seizure and death. It is not said, but it may be presumed the kidneys were healthy. Here there was profound unconsciousness, but surely no material increase of pressure; some other cause must, therefore, have been in operation. Again, think of cases of hæmorrhage into the pons varolii where there is no unconsciousness, or only some degree of stupor for a longer or shorter time after the seizure. Why, if pressure be the cause of the paralysis of the cerebral hemispheres, should cases having very similar lesions differ so much in respect of this symptom? Further, there are a good many cases on record where large cysts or abscesses have existed within the skull without giving rise to any symptoms until near the close of life. These must in most instances have caused a good deal of undue pressure, though it may have been lessened to a varying extent by wasting of the brain tissue. The convolutions in a case recorded by Dr. J. W. Ogle were greatly flattened by the pressure of a large quantity of fluid in the ventricles, but, though the patient had previously been comatose, he became quite sensible and conscious a few hours before death.—*Vide* "Path. Tr.," IX, 27. Dr. Reynolds found several large hydatid growths in the brain of a young girl who had never suffered in any such way as to lead to the suspicion of cerebral mischief. These cysts would almost certainly expand faster than the cerebral tissue would waste. Dr. Barker relates the case of a lad, æt. 14, who was supposed to be in perfectly good health until he had an attack of sunstroke about four weeks before death; this gave rise to special symptoms, viz., sudden temporary unconsciousness, blindness, absolute in the right eye, and, finally, delirium, in which he died. At the *post-mortem* there was found in the posterior lobe of the left cerebral hemisphere an hydatid cyst, occupying nearly the whole lobe, which was rendered irregular and lobulated, and was enlarged in its dimensions. There was no subarachnoid fluid, the convolutions being compressed against each other, and against the parietes, so as to obliterate the sulci. The inner surface of the skull presented a series of shallow depressions separated by angular ridges, evidently produced by the long continued pressure of the subjacent convolutions of which they presented an accurate mould. There can be no doubt that in this instance very undue pressure had for a long time been exerted by the cyst, but it does not seem to have caused any symptoms.—*Vide* "Path. Tr.," X, 6. Again, there are cases such as one recorded by Dr. R. Bennett, "Path. Tr.," XIII, 5, where two largish cysts, the larger holding 6 oz., produced very notable symptoms—severe pain in head, widely dilated, and fixed pupils, occasional epileptic attacks, loss of control over the legs, and palsy of sphincters, but no impairment of intelligence. As the cysts were situated in the right cerebral hemisphere there can be no doubt that the pressure must have told on these parts. Yet it did not affect their function. Lastly,

I adduce Pagenstecher's experiments, of which an account is given in the *Brit. Med. Journ.*, 1872, I., p. 372. They consisted in injecting between the dura mater and skull of dogs a melted mass of wax and lard under a pressure of 80 to 120 millimetres of mercury. Death did not ensue unless the pressure was increased to 180 millimetres—*i.e.*, equalled the blood pressure. Taking the capacity of the skull in man as 1300-1400 cub. in., he calculates that it is necessary to have a mean amount of 37.7-40.6 cub. in. of blood, or a maximum of 84.5-90 cub. in. in order to produce symptoms of compression. This would give 23 oz. of blood as about the mean quantity requisite to produce compression-symptoms,—an estimate which certainly seems excessive according to our clinical experience, but which, even if considerably reduced, may lead us to question whether small quantities of fluid as 4 or 6 oz. are capable of causing injurious pressure.

If now, all the above considerations lead us to assign to anæmiating pressure a very inferior efficacy to that with which it is usually credited in the production of paralysis, coma, &c., I see no other cause which can be invoked than *irritation*. Some are disposed to quarrel with this term as conveying (they say) no definite idea, but I think there is no doubt it expresses a reality, though we may not be able to determine precisely the morbid condition. At any rate, we are sure that the ends of the torn fibres at the edge of an hæmorrhagic cavity are in a very unnatural condition, and it cannot be considered improbable that the nerve cells, with which their other extremities are connected, should be injuriously affected thereby. If an effusion of blood into the peritoneal cavity is apt to cause severe peritonitis, is it likely to be without effect in a far more delicate and highly-organised tissue? There are quite sufficient instances of the effect of irritation of peripheral nerves to establish the point that various nerve centres may have their action seriously impaired, or even arrested thereby. A tapeworm in the bowels may cause severe headache or vertigo, lead colic may cause failure and cessation of the heart's action, neuralgia of the first division of the fifth may paralyse some of the muscles of the globes. If I were pressed for a definition of irritation I should say it was the result of a *morbid stimulus*, which impairs functional energy, while *healthy stimulation* promotes it. The great efficacy of the morbid impression produced by the lesion—apart from mere loss of substance, or mechanical pressure—seems to be clearly displayed by the vastly greater constancy with which a suddenly-produced damage operates than one which ensues slowly. A very large abscess, or cyst, may cause no symptoms, but a small hæmorrhage is almost certain to occasion very decided ones. The chief difference in these instances relates to the rapidity with which the morbid change is produced. The effects of shock—*i.e.*, of a sudden severe irritation—are well illustrated by the following cases recorded by Mr. Callender, "St. Barth. H. R.," Vol. III.:

No. 39.—G. H., watchmaker, complained of weak vision, and as he worked had headache. He seemed to be in his ordinary health, when, early one morning, he suddenly rose up in his bed, and fell back dead. The whole of the left posterior and half of the middle regions of the brain, from vertex to base, were occupied by one large abscess, containing ordinary yellow pus, a mere shell of soft-brain tissue surrounding it. In front, it had extended through the back of the optic thalamus and had burst into the middle horn of the lateral ventricle, flooding both it and the adjacent cavities with pus.

No. 41.—L. J., æt. 30, admitted for phthisis. Two days before death he suddenly became insensible, no brain symptom having previously existed. In the right posterior and half of the middle region of the brain were several large abscesses full of fetid pus, and one of these had extended forward, and completely hollowed out and destroyed the optic thalamus. The symptoms had resulted from the bursting of this abscess into the right ventricle.

No. 42.—C. S., æt. 31, died suddenly without having been previously ill. Abscesses were found in the right

half of the cerebellum, two at its middle part, three in the right middle region, one in the upper middle region close to the margin of the longitudinal fissure, and one larger than all in the middle region just above the corpus callosum. This last had burst into the subjacent right ventricle.

In none of these cases could there have been any increase of intra-cranial pressure, but merely transfer of morbid fluid from one cavity which tolerated its presence to another which was extremely intolerant of it. In two of the cases the result was immediate death, owing probably to the inhibitory action of the morbid stimulus on the cardiac filaments of the vagi nerves. In the third it was sudden insensibility, implying, I conceive, a similar operation on the hemispheres. When an hæmorrhagic cavity bursts into the ventricles the result is sometimes profound coma only, sometimes, as in a case under my care, frequently recurring convulsions and coma. Now, convulsions are admittedly a result of irritation, and as they occur under the same circumstances, may not coma be too? There is an interesting instance of paralysis produced by cerebral lesion, which is well worth our remarking on here—that, namely, of the sphincter ani. This certainly most coincides with coma, but may be present, together with the paralysis of the sphincter vesicæ, where the intelligence is perfect, as in Dr. R. Bennett's case above referred to. The paralysis, Dr. Todd states, is so complete, that not the slightest resistance is offered to the introduction of the finger into the anus. Now, it seems to me unquestionable that the sphincter ani is largely under the sway of the lower portion of the cord, that it constitutes, together with the cord, an excito-motor apparatus. Its spasmodic contraction in states of irritation of the covering integument illustrates this very well. But it is also under the influence of fibres descending from the centres of volition, and when these are subjected to morbid impressions the sphincter comes to be paralysed inhibitorily. The catastrophe alluded to by Juvenal as produced occasionally by the war-trumpet—"et trepidum solvunt tibi cornua Ventrem," and the analogous effect of an impending examination not unknown to candidates for M.R.C.S. are similar instances in which a depressing emotion takes the place of the morbid impressions of coarse disease. The notorious variability of the symptoms in cases of intra-cranial lesion seems to be better accounted for on the view I maintain than on that which attributes everything to anæmiating pressure. For if this were all, the effects of a certain amount of pressure within the skull ought to be nearly uniform, allowance, of course, being made for the situation of the foreign body and for the local damage it may have produced; but if it is not only the pressure that has to be considered, but the irritation existing, then the result may vary greatly in different individuals according to the greater or lesser susceptibility of different centres to undergo derangement.

The lateral deviation of the eyes observed in this instance is not an unusual, though by no means a constant, occurrence. It is met with in cases of unilateral epilepsy, and appears to me much more like a spasmodic than a paralytic symptom. It might certainly be produced by paralysis of one internal and one external rectus, but as it is evidently a secondary result and can be produced by irritation, I hold the latter to be its most probable cause. The nerves which are accustomed to act together in health are also associated in morbid action.

The rapid respiration coinciding with profound coma increasing in frequency up to the time of death was so unlike what is usually held to exist in coma that it may well seem strange to you, as I remember it did to me when I first observed it. It is not, I suspect, a very rare phenomenon, as I have seen three cases without looking out specially for them. It is difficult to account for the phenomenon satisfactorily, but it may be in this as in other instances that a cause which usually generates paroxysms often generates in place of it hyper-excitability.

The rapid and feeble action of the heart may with much

reason be ascribed to paralysis of the cardiac branches of the vagi.

Now, returning to my questions, the answers which seem to me most accordant with all the facts are (1) that the paralysis of the hemispheres conditioning unconsciousness depends mainly on deranged action of the nerve-cells of the convolutions by the morbid impressions conveyed to them from the seat of lesion; (2) that death ensues either from similar irritation affecting the respiratory centre, and rendering it unexcitable by the "besoia de respirer" sensations conveyed by the vagi, or from inhibitory arrest of the action of the heart by the vagal filaments joining the cardiac ganglia.

As the idea of inhibitory irritation may not have been readily assimilated by all my hearers, some of whom may think that irritation must always conditionate an active state of nerve and muscle, I am glad to cite the following authorities in support of my views:—Dr. J. W. Ogle ("Med. Chir. Trans., 1859") applies the term induced to cases of paralysis, where he believes "an irritative action is carried by the intervention of commissural fibres from a given point to another part (and that, too, of the opposite side of the brain), and there induces a repressive or inhibitory action of some kind or other of motor nerve fibres." Messrs. Mitchell, Morehouse, and Keen ("Report on Reflex Paralysis") consider "it possible that a very severe injury of a part may be competent so to exhaust the irritability of the nerve centres as to give rise to loss of function, which might prove more or less permanent." Dr. Todd ("Physiolog. Anat.," I., p. 349) recognised the great difference between simple excision of a centre, say the corp. striat., and a diseased state of it from inflammation or clot; "the one simply cuts off the influence of the will, the other affects the vital action, and consequently the vital power of the centre and of the commissural fibres connected with it." Brown-Séquard states (*Lancet*, 1861, I., p. 2) that symptoms of cerebral disease may be the effects of three different causes: (1) Direct injury or disease of the brain; (2) alterations in the quantity or quality of the blood; (3) a reflex influence starting from an altered part of the brain, or some centripetal nerve extremity. Dr. Todd, commenting on a case of arachnitis, attended with hemiplegia and rigidity of the paralysed muscles, says that it is due to a cause "which exercises at once a paralyzing and irritating influence on the brain," and that this influence is propagated to the spinal cord, and so through the nerves to the muscles" ("Clin. Lect.," 1854, p. 224). He states at p. 231 that it is "not an inflammatory state of brain only which may excite this rigid palsy, but one of irritation, whether inflammatory or non-inflammatory." The cause of the disorder may be located either in the substance of the brain, or, as in a case he refers to, between the bone of the dura mater, so that it is not necessary there should be actual damage of the palsied centre.

Now, if I have carried you thus far with me, you will probably be inclined to admit that cerebral symptoms, in cases of hæmorrhage, and in other kinds of lesions, may be separated into two groups,—one comprising those which we believe to depend on direct injury and damage to the machinery; the other, those which are generated by the irritation set up by the original lesion, and conveyed by commissural fibres to adjacent centres. The former we may distinguish as *primary* or *necessary*, the latter as *secondary* and *varying*. Thus, in a case of moderate-sized clot in the corp. striat. we have hemiplegia on the opposite side as the primary result, while unconsciousness, lingual and facial paralysis, disorder of the respiration and circulation may be enumerated as probable secondary results. Dr. Hughlings Jackson writes,—"A patient may have a large clot in his brain, and yet his respiration and circulation may be quite normal, 72 and 14 per minute." But after an interval, which may vary greatly, the respiration may become quick, and the pulse rapid, or also irregular or slow. The appearance of these secondary symptoms announces great danger. Now, the practical value of the

view I am advocating is, that these symptoms not being necessary results—at least, very often not—of the actual lesion, we may rationally hope to mitigate or remove them by treatment; and, on the other hand, we shall be cautious not to do anything which might promote their occurrence. Irritation will, in all probability, tell more severely on an exhausted than on a stronger system, and instances are not wanting where depletion seems to have actually promoted the invasion of paralysis. In a case of ordinary cerebral hæmorrhage we should figure to ourselves the brain as having suffered a serious injury, probably in or near the large basal ganglia. Nothing we can do can have any speedy effect on the actual lesion; the most that we can hope is to prevent its extension, and promote cicatrization. In most cases, it seems to me that ergot and astringents would be far more likely to accomplish this than any kind of depletion, which would probably still further depress the already enfeebled *vis nervosa*. Then as to the unconsciousness, and other secondary or induced symptoms, it surely seems rational to deal with them as conditions of prostration and paresis, brought on by the shock or irritation to which the associated centres have been subjected. Trousseau attributes the unconsciousness to *étonnement cérébral*, to a sort of concussion, and lays down, as a rule, to maintain and support the patient's strength. From this he does not deviate, even when a notable febrile movement with hyperæmia of the face supervenes. This is probably due to a vaso-motor paralysis, the result of the injury, and may be considered identical with the paralytic pyrexia so well described by Mr. Hutchinson as occurring after injuries to the spinal cord. One can quite understand, on this view, how useless, or even injurious, bleeding would be to remove such a state. The matured experience of the great French clinician is the practical justification of the theoretical views I have brought before you.

Understand, however, that I am far from denying the important part played by pressure in many instances, especially of surgical lesion; or from over-looking the possibility that the lesion may be multiple; or from affirming that it is a matter of indifference where the primary lesion is situated. Neither do I advise you to forswear purging or even bleeding if there be reliable indications of oppressive cerebral hyperæmia, active or passive, and the action of the heart is labouring. But I do ask you to consider well whether there does not exist good ground in the majority of head cases for attributing, at least, as much importance to irritation as to congestion and effusion in the genesis of symptoms.

ABSTRACT OF

LECTURES ON MYOLOGY,

AT THE

ROYAL COLLEGE OF SURGEONS OF ENGLAND,

By PROFESSOR HUMPHRY, F.R.S.

LECTURE III.

In his third and last lecture Professor Humphry continued the discussion of the muscles of the limbs. The *coraco-brachialis*, *biceps*, and *brachialis anticus* he showed to form one series corresponding with the *adductor*, the *semimembranosus* and *semitendinosus*, and the short portion of the *biceps cruris*; while the long portion of the last muscle is a derivative from the extensor mass—the *gluteo-rectus* series—which, inclining to the plantar aspect, has acquired a flexor action. The tendinous intersection in the *semitendinosus* he regarded as corresponding with a similar intersection in the *Cryptobranch* found at the junction of the caudal muscle with the flexors of the leg; and its persistence in man is to be associated with the great length of the fibres of the

muscle, owing to the distance of its insertion in the leg from the centre of motion at the knee, and the consequent great range of its action. The fibres of this muscle in a woman of ordinary stature measured ten inches, while those of the *semimembranosus* measured only three inches, and those of the *biceps* six, the length in each instance being proportionate to the distance of the insertion from the centre of motion. The *quadriceps cruris* is evidently the serial homologue of the *triceps brachii*; and in the Bat, where the rotation of the hind limb is the reverse of that usual in mammals, the *rectus cruris* arises from behind the acetabulum, just as the scapular portion of the *triceps* usually arises from behind the glenoid cup.

The several muscles on the flexor and extensor aspects of the middle and distal parts of the limbs were described as derivatives or segmentations from pronator-flexor and supinator-extensor masses, which are found in a simple form in tailed Batrachians, but are more complicated in man. The divisions of these were described at some length. The supination and pronation in the upper limb, and the throwing out of the heel bone in the lower limb, are the features which necessitate the chief differences in the disposition of the muscles in the two limbs. A large proportion of the fibres on the plantar aspect in the hind limb are concentrated upon the heel, and subserve to the flexion of the ankle; whereas the corresponding fibres in the fore limb minister to pronation of the forearm and flexion of the digits, as well as to flexion of the wrist. Hence the representatives of the *flexores carpi* and the *flexor sublimis digitorum*, as well as of part of the *pronator teres*, are to be found in the outer head of the *gastrocnemius* and the *soleus*; the *plantaris*, which in many animals is continuous with the *flexor brevis digitorum pedis*, being the representative more particularly of the *f. subl. dig. manus*. The ulnar origin of the *pronator teres* and the *accessorius pedis* are remnants of the primitive pronator-flexor masses which have attachments to all the bones of the limbs. The former is present in the Chimpanzee, but is not again met with till one reach the Reptiles, where it constitutes a *pronator intermedius*, connecting the *pronator teres* with the *pronator quadratus*. Its use is to carry on pronation during the flexed condition of the elbow when the humeral fibres of the muscles lose their power. The use of the *accessorius* is in like manner to maintain the influence of the flexor digitorum upon the toes in the flexed position of the ankle. A well-marked *accessorius*, corresponding with that in the hind limb, is found in the fore limb in some of the Saurians; but there is no such muscle in the fore limb of birds or mammals.

The Professor concluded his course by some remarks on the difference between a hand and a foot, first converting the distinction drawn by the Rev. Prof. Houghton, from a supposed difference between the flexor tendons in the two. He observed that we must eliminate the features of difference between the terminal parts of the hind and the fore limbs; forasmuch as these relate to the distinction between the two limbs rather than to the distinction between a hand and a foot. This he said had not been sufficiently attended to by those who had recently considered the question, and, therefore, they had argued it upon a wrong basis. Pointing out the features which distinguish the hand of man from the terminal part of the fore limb of ordinary mammals, he remarked that a corresponding modification either of a fore or a hind limb would constitute a hand, although the features distinguishing either from the other were still present. Judged by this rule, the terminal part of the hind limb of a gorilla or a chimpanzee, notwithstanding its projecting heel and the presence of a peroneus muscle, has as much claim to be called a hand as the terminal part of the fore limb of the same animal. There is, therefore, no sufficient anatomical reason for rejecting the word "quadrumanous" as applicable to them, or the word "bimanous" as characteristic of man.

THE ARMY SURGEON, HIS WORK AND WORKS (a).

By C. A. GORDON, M.D., C.B., Dep. Insp.-Gen. of Army Hospitals.

FELLOW GRADUATES,

My first duty is most gratefully to acknowledge the high distinction the members of the St. Andrew's Medical Graduates' Association have been pleased to confer upon me, in selecting me as the medium through whom they desire to manifest their good-will towards their professional brethren in the army, for in this light only can I look upon the circumstance to which I owe the honour of now addressing you.

It is not often that a member of the military body is favoured as I am on this occasion. Our sphere of action is usually far removed from this great capital, our vocation very different from that of preparing addresses to read before learned and scientific associations; yet it is pleasant and flattering to us as a body to find that we are not altogether forgotten, that if out of sight we are not completely "out of mind."

It is true that novelists and popular writers have on some occasions been so good as to give, for the edification of their readers, a portraiture of the army surgeon. Thus, who has not laughed over the fussiness and irascibility of Slammer? Who has not been amused at the vagaries of Maurice Quill, who entered the 31st Regiment, to be near his brother in the 32nd, who, as surgeon of his distinguished corps, "was at the head of his Profession," and being so, had "nothing more to look forward to or expect"? Or do you accept as correct the picture conveyed in that very charming fairy tale, "The Water Babies," where the talented author tells us that when Mrs. Bedone-by-as-you-did determines to call up before her all who have ill-used little children, and serve them as they served the children, "first, she called up all the doctors who gave little children so much physic, and set them all in a row, and most miserable they looked, for they knew what was coming; and first she pulled their teeth out, and then she bled them all round, and then she dosed them with calomel and jalap, and salts and senna, and brimstone and treacle," and so on? But then it is explained within parentheses, that those so treated were for the most part old ones, for the young ones have learnt better—all but a few *army surgeons* who still fancy that "a baby's inside is much like a Scotch grenadier's." Well, perhaps we have to wait until the baby develops into the man, "the soldier," now no longer "bearded like the Pard," "full of strange oaths," perhaps, yet who wins our battles and maintains England's honour, before we fully appreciate his "economy," interior and general. Babies, too, I may observe, like the red man who disappears before the march of civilization, are threatened with utter abolition, under the "latest thing out" in army re-organisation, so that in regard to them our occupation will soon be gone, it may be to their advantage, only the test cannot be applied; certainly to our comfort and peace of mind.

But I must endeavour to tell you a little of what our duties are, what we have done for the soldier and the Profession, and what we have learnt from the great war so recently ended. A very few remarks will serve to explain the general nature of our functions, and of the interests confided to our charge. The great object of our existence as a department is to maintain the physical efficiency of England's armies, in connection with which duties interests depend more important than it is possible to appraise according to mere money value. Success or failure of a military expedition may depend upon a relatively small number of men, the more or the less, ready and capable of being brought to bear upon a given point at a particular time; hence the obvious importance of preserving health under such circumstances.

(a) Presidential Address delivered at the St. Andrew's Graduates' Association, on Saturday, July 6th, 1872.

Unhappily, experience has taught us that in protracted wars, large as has of late years been the list of casualties in battle, they are, to those by disease, but as one to seven, or even eight; hence the urgent necessity of judiciously arranged measures for the prevention of such diseases as we know to be incidental to active service. In all countries, except those that have the advantage of western civilization, whether an army be advancing or retiring, it becomes necessary to carry along with it its sick and wounded, or at least take measures to protect them alike against the enemy and the population. Under such circumstances, also, the presence of a number of helpless men becomes a greater source of weakness than so many casualties in battle. In the one case, not only must the men be fed and accommodated, but they must be carried; the men and animals employed in their transport, in addition to being similarly attended to, must be provided with means of protection, to the still further weakening of the force; while in the latter case no such arrangements are needed. Here, then, are conditions in reference to which our duties become of the highest importance. Let the fact also be borne in mind that wars are now no longer carried on as they were even a few years ago. Where thousands of soldiers were wont to be engaged, tens of thousands are so now. The congregation of increased masses necessarily increases their liability to camp diseases, and thus vigilance on the part of the Medical officers becomes more essential than it has hitherto been. While increased strength of military forces has become necessary, the money value of human labour has increased, as also the requirements of the soldier-yielding population of the country; hence the injury and hardship inflicted upon that portion of the people by such calls as would become necessary to fill the ranks reduced by wounds and disease, would far exceed anything it has hitherto been, showing, were this necessary, that more than ever must we study by every means in our power to economise human life in armies. See, also, the influence through the army upon the conditions of our civil population. Our recruits are selected lives, and being so, withdraw so much of the health standard; leaving, in the persons of those rejected, the more or less diseased. The greater the number of soldiers thrown back upon civil life affected with disease, the greater the burthen they become to society, the greater the expense by reason of protracted sickness, and often crime into which they fall, and also the greater the injury to public health through the diseased children they propagate. Hence it is that the influence and vocation of the military surgeon, although chiefly exerted in the army, are by no means limited thereto, but pervade civil life to an extent greater, no doubt, than is at first recognised.

Not only does the surgeon in the army perform toward the classes under his charge the ordinary professional duties of his brother in civil life, but, in addition, a large number to which the latter is altogether a stranger; and, except in times of actual war, or during epidemics, the attendance on the sick, important and responsible though it be, forms really the least considerable of his many functions, while as he rises in the service, his duties bear more upon the management of masses than of individuals.

(To be continued.)

CASE OF RETAINED PLACENTA.—SUCCESS OF ANTISEPTIC TREATMENT.

By FRANCIS M. LUTHER, M.D.

ON 2nd May last, about 6 o'clock p.m., I was called by Dr. Hartland, of Villierstown, to see Margaret Brien, of Aghlish, and consult with him on her case. She had been delivered of a still-born infant (footing) about twenty hours before I saw her. Ergot had been exhibited during the labour, and immediately after, the uterus contracted so powerfully that the introduction of the hand became

impossible, and traction of the cord was unavailing to dislodge the placenta, which was evidently adherent. Two months before the woman suffered from symptoms like the approach of labour, very possibly adhesion from inflammation took place at this date. Dr. Hartland repeated his efforts many times. There was no hæmorrhage whatever, and he left intending to resume his attempts, after allowing the patient to rest; but he was called to another confinement case, and when able to return to her, thought it better to have a consultation.

My hand is very small, and I am in the habit of introducing it into the uterus very constantly, if gentle traction does not at once bring away the placenta, for I consider immediate delivery, and maintaining manual pressure upon the uterus, instead of at once applying a binder, removes a great many of the dangers to which women are subject after the infant is born. However, in this case, I could barely introduce two or three fingers within the cervix. I felt the insertion of the cord in the placenta, but could by no means open my fingers. The case seeming desperate, I got the midwife to press down the uterus externally, and made traction on the cord. The whole body of the uterus was drawn down into the vagina, but the placenta did not loosen, and after more attempts the cord unhappily broke at its insertion. We then nauseated with tartar emetic, but, instead of relaxing, the uterus only contracted the more. We let her rest some hours, while consulting upon her case. I suggested the Cæsarian section, but Dr. Hartland disapproved of it, nor would the husband hear of it for a moment. I now think Dr. Hartland did right to withhold his sanction to so formidable an operation. However, we thought it right to have another consultant, who unfortunately was attending another labour case when he got our message. After several hours' delay (I forgot to say that we tried chloroform as well as tartar emetic to cause relaxation with no effect), we considered the contraction permanent, and giving a dose of chloral to produce sleep, arranged to see the woman next day, or rather, same day, for it was then 2 o'clock a.m., and consult if anything could be done to give her a chance of life. We found her with a pulse of 120, desponding and anxious, unable to move in the bed.

Treatment.—Half a teaspoonful of sulphurous acid in half a tumbler of water every three hours. Sprinkle carbolic acid freely about the floor and on plates, so as to impregnate the air of the room with its odour. Ordered whey. Dr. Hartland and I thought it useless any longer to seek to remove the placenta by introduction of the hand; not only useless, but dangerous.

We determined to give the antiseptic treatment a trial, though with little hope of a favourable result. I did not see the patient next day. Dr. Hartland did and considered it advisable to order wine and beef-tea. On the 5th we both saw her. She had had rigors, her pulse was over 120. There was pain in the knee, but she had the suck. Tongue dirty. We found that the sulphurous acid had not been given regularly. Increased the dose to a drachm in a tumbler of water every three hours. Impressed the importance of its regular administration, and in order to secure this, gave a somewhat more favourable prognosis than we had done; used injections of weak carbolic lotion twice a day; wine, beef-tea, arrowroot. She could not at this time move in bed without help. Next day Dr. Hartland told me that she had bilious vomiting and some rigors; but on the 7th the pulse, though weak, was nearly natural. She had no pain anywhere, and could move freely in the bed. The uterine tumour was very small and not tender; tongue furred.

To take hydr. δ . cretâ and castor-oil, and everything else (antiseptics) as before. On the 8th, Dr. Hartland found a large piece of placenta protruding from the os, and removed it; some vomiting and rigors; bowels acted freely; slight bronchial wheeze; pulse over 100; otherwise well. On the 11th another large piece of placenta was expelled. There was no rigor, but the pain

in the knee returned, and there seemed to be some effusion into the joint. However, it was not tender on pressure, and neither flexion nor extension caused pain. Dr. Hartland had it wrapped in cotton wadding covered with oiled silk. The tongue continued a little furred. I did not see the woman after this, but Dr. Hartland wrote to me that from this date there were no bad symptoms of any kind; the effusion yielded to tincture of iodine, and the patient made a perfect recovery. This happy result, I incline to think, was due to the constant exhibition of the sulphurous acid, and the injection of carbolic or chloralum lotions, which Dr. Hartland administered twice a day. The frequent rigors and pain in the knee showed that pyæmia was imminent; but as the antidote was given in anticipation and in large and sustained doses, it was aborted, as ague is by quinine, until finally the rotting placenta was expelled, and the "avenues to death" permanently closed. Indeed, the extremely contracted state of the uterus throughout, doubtless, hindered in some measure purulent absorption. Dr. Hartland permitted me to see the woman with him from time to time, as I was greatly interested in the case, from its rarity and dangerous character.

However, in Dr. McCarthy's translation of the (*Paris*) *Journal of Practical Medicine and Surgery* for February, 1860, I am surprised to see a statement of M. Pajot's, that "out of 180 women who, from one cause or another, were not delivered a few hours after their confinement, eight died." I think there must be a typographical error, and that for "eight" we should read "eighty," or else the statistics must include cases of abortion where the retention of the placenta is not so often productive of fatal consequences apart from hæmorrhage.

AMERICAN MEDICAL ASSOCIATION.

OUR readers have had an opportunity of perusing selections from the address of Dr. Yandell, the president this year, which will afford some idea of the influence of the association and the opinion of the Profession in the States as to its value and its work. We do not propose to enter into what may be called the Medical politics of our brethren in the great Republic, nor can we even undertake to epitomise the several reports of the proceedings that have reached us in our exchanges. Especially would it be inconvenient to occupy this column with remarks on the several points that were raised for discussion in reference to the Profession and its relation to the public. We feel, however, a deep interest in all that concerns our American brethren, and congratulate them in all those events which seem to entitle them to our sympathy. Our present object is to speak of some of the more practical proceedings in the sections, for the sake of giving our readers an estimate of some of the solid work being done. Selecting from the *Record*, which gives a very complete summary, a few points, we will classify them for the easier reference.

OVARIOTOMY.

Dr. Washington L. Atlee, of Philadelphia, described in minute detail his own method of preparing the patient, of operating, and of after-treatment. Among the points brought out were these: For evacuating the bowels beforehand, he preferred castor-oil to any other means. As an anæsthetic he always employed a mixture of chloroform and ether, equal parts. During the operation the patient must be kept warmly covered with blankets, only the abdomen being exposed. Except when compelled to, in very rare cases, he never made the incision more than three inches in length, and he did not think that even extensive adhesions often required a longer one. In examining for adhesions he decidedly preferred using his fingers to sweeping a sound around the tumour, as advocated by Dr. White. For the pedicle he had invariably of late years employed the clamp, and he noted certain advantages in his own form of this instrument. He had once lost a patient by strangulation of the in-

testine from its adhesion to the stump; and, thinking this accident liable to occur again, he had never since returned the pedicle into the abdominal cavity. As a compress and support for the abdomen, he preferred thick layers of cotton covered by a broad band of muslin. This was soft and warm. His after-treatment was expectant, opium or chloral hydrate being given only when indicated, and by the rectum or hypodermically, if not tolerated by the stomach.

ELECTRO-THERAPEUTICS.

Dr. George M. Beard, of New York, read a paper on *Recent Researches in Electro-Therapeutics*. He spoke of the great and rapid improvements in apparatus, claiming superiority for America over Europe in this respect at present; and exhibited a battery and its attachments made by the Galvano-Faradic Manufacturing Co. of this city. He demonstrated his methods of "localised electrification," "general Faradisation," "electrolysis," and "central Galvanisation." This last consisted in "placing the negative pole at the pit of the stomach, and applying the positive over the head, sympathetic, and pneumogastric in the neck, and down the spine, so as to bring the whole central nervous system under the influence of the current." It had proved very useful in certain obstinate skin diseases, as well as in hysteria, neuralgia, neurasthenia, and many other nervous affections.

Among the points he had recently demonstrated were these:—

The nutrition of children was often much improved by general Faradisation. Two pups of a litter of four were treated by the speaker in this manner, and were found at the end of a month to weigh several ounces more than their mates.

Children bore electricity better than adults; but some constitutions could not endure it, however administered.

Malignant growths could sometimes be treated with great advantage by a method of "working up the base electrolytically." The advantages of electrolysis in the treatment of these tumours were less hæmorrhage, less shock, less danger of pyæmia, and more rapid healing. It would almost always relieve the pain of tumours, but did not prevent constitutional infection.

Dr. A. B. Crosby, of New York, spoke of a case of chronic eczema of the leg under his care, which had resisted other treatment, but was decidedly improving under "central Galvanisation," as just described. Also of a case of organic stricture of the rectum, where he had assisted Dr. Beard in an electrolytic operation after returning the sphincter.

VASO-MOTOR PHYSIOLOGY.

Professor Henry Hartshorne, M.D., of Philadelphia, read a paper *On the Present Condition of Vasomotor Physiology*. He remarked that, having in 1856, in an "Essay on Arterial Circulation," published in the Transactions of the American Medical Association, advanced views somewhat at variance with the prevailing opinions, he had been led to believe that, recently, the progress of inquiry had developed facts which approach to a demonstration of the truth. Currently it has been held, as stated in the works of Virchow, Bernard, Huxley, Marey, B. W. Richardson and others, that the whole function of the muscularity of the smaller arteries (incorrectly confounded sometimes with the capillaries) is, to limit by a flood-gate or stop-cock action, the flow of blood caused by the impulse of the heart. Against this view, there have been the opinions and reasonings of John Hunter, Sir Charles Bell, and a few others of the older writers; and an overwhelmingly strong presumption derived from general physiological analogy. Dr. Hartshorne wished to point out the progress made since the publication of Prof. Lister's observations in 1858, and, more especially, the recent very important contributions toward it by Legros and Onimus (*Journal de l'Anatomie et de la Physiologie*, 1868-70). It was necessary, in order to perceive the bearing of the facts thus brought forward, to review briefly the whole ground of the inquiry. Attention was therefore called to the following points:—

1. Bowman, Marey and others have abundantly demonstrated that the universal law of muscular fibre, pre-eminently obvious in the smooth muscle of organic life, is alternating, rhythmic or peristaltic contraction. Presumably, therefore, we should find this true of the middle coat of the smaller arteries; and the burden of proof rests with those who assert the contrary. And, if it be alternating, we have every reason to believe that it is *propulsive*, not restrictive in its action.

2. Certain facts in comparative physiology are only to be thus explained; as, the completeness of the round of cir-

ulation in fishes with only a respiratory heart; the arterial dilatations taking the place of the heart in *amphioxus*; the distribution of arterIALIZED blood from the reservoir-like arterial networks of the whale; the ordinary circulation in most articulates, which have no heart.

3. *Acephalous fetuses* are always *acardiac*; the propulsive power of the arteries is necessary to carry on their circulation. At a certain stage of development, every human fetus is likewise *acardiac*, as truly as an insect or a myriapod.

4. Erectile tissues have been recently and carefully studied anew by Legros, who has decided that the evidence shows that "it is indeed the *contractile element of the arteries* which acts to produce erection."

5. Many familiar cases of physiological erethism are (as pointed out in Dr. Hartshorne's Essay of 1856) manifestly of an active character. Such are—the determination of the blood to the maxilla in dentition; to the ovaries in ovulation, the uterus in gestation, the mammae in lactation, and the testicles during the heat of male animals; the vascularity of the newly-growing antler of the deer, &c. To none of these instances can the idea of "paralytic dilatation" of the vessels, with any show of reason, be made to apply.

6. Further facts are these—in paralysed limbs the pulse is often diminished in force and fullness; when mortification occurs, or a limb is crushed by a railway car, or torn by a gunshot wound, little or no hæmorrhage occurs. Here a truly paralytic state of the arteries is produced, and the blood ceases to flow. Under some other circumstances there is, of course, a paralytic dilatation of the vessels; as when they are exhausted by fatiguing over-contraction, or when the sympathetic nerve has been divided, as in Bernard's famous experiment with the rabbit's ear.

In decapitated criminals, Robin observed that the blood does not spout from the divided carotid and vertebral vessels, but goes on through the head. Legros and Onimus found that when the large vessels are tied in animals, the circulation continues; in cold-blooded vertebrated animals, for a considerable time. Chauveau similarly found that firm compression of an arterial trunk, so as to obstruct its current, does not always arrest pulsation; and Legros and Onimus observed, in the retina of a man whose *arteria centralis* had been obliterated by a clot, distinct waves of pulsation still continuing in the minute vessels.

7. Dr. S. W. Gross's paper (a) was cited, showing the important influence of compression of an arterial trunk supplying blood to a part in a state of inflammation; the active participation of the arteries in that morbid process being thus made clear.

8. Application of these general facts to pathology becomes now important; as, in reference to the nature of the condition ordinarily called fever; the spasmodic constriction of the blood-vessels in cholera,—unduly restricted by Dr. George Johnson to those supplying the lungs; and the explanation of the hypertrophied state of the blood-vessels of the kidneys, often found to occur in Bright's disease.

Lastly, it is concluded that we have now proof enough to show positively that *there is a true arterial systole*, following and carrying on the propulsive movement of blood begun by the heart, instead of the mere "stop-cock action" accepted still by most writers. In favour of this last, there is really *nothing* except the somewhat hasty interpretation of one or two galvanic experiments by the Webers, more than twenty years ago; and the taking for granted a conclusion from them, in contradiction to all general analogy. It may be considered that the true factors of the pulse are four:—1. The heart's impulse. 2. The elastic contractility, especially of the larger arteries. 3. The closure of the aortic valves. 4. The *muscular arterial systole*. As this last occurs *after* the others, and in an artery so remote as the radial at the wrist, as late as the second sound, accompanying the shutting of the aortic valves, its effect must be to *aid* in propelling the blood. It cannot be *nil*, because it empties the arteries after death. It is not a persistent rigidity or tonic contraction, or else it could be felt in some arteries in the intervals of the pulse, as it cannot. On the whole, it would appear that, on this subject, with a vast deal of laborious experimentation, some want of care in reasoning has left the problem unduly long in reaching a final solution.

THE LEUCOCYTE.

Dr. Jos. G. Richardson, of Philadelphia, Chairman of the Committee "On the Structure of the White Blood-Corpuscles,"

(a) *Philad. Med. Times*, Jan. 10, 1871.

presented a report on that subject. After a brief review of our present knowledge in relation to this important morphological element, he remarked:—

"From this abstract it appears that Stricker and Rollett, who upon this subject occupy the front rank among German microscopists and histologists, whilst inclining somewhat to the view that the white blood-corpucle, at least in certain stages of its development, possesses a cell wall differentiated in structure from the cell contents, do not accept as proven the existence of such a membrane; that they also consider that the laws according to which leucocytes take up fluids are unknown, although they deem it probable that diffusion plays a part in the process; and further, they seem to think that the molecular or 'dancing' movement in the salivary corpuscles, differs from that seen under certain conditions in colourless blood, pus, and other corpuscles, inasmuch as it ceases on the addition of from one-half to one per cent. solutions of common salt, which, they say, still permits the movements of fresh pus or lymph corpuscles to continue."

After a series of experiments, performed to further elucidate these three points left undetermined by Prof. Stricker, in which he studied the effects of chloride of sodium, chloride of iron, and ferrocyanide of potassium solutions of various strengths upon the leucocytes of blood, pus, mucus, and saliva, the writer concluded that—

"The white blood-corpucle is a cell composed of a nucleus (or nuclei), which latter possesses the power of voluntary amoeboid movement, is insoluble in water, but is capable of slowly imbibing that fluid and increasing to nearly double its normal size. The cell wall of the corpucle is a membranous envelop, insoluble in water, too thin to exhibit a double contour with a magnifying power of 1,200 diameters, but firm enough to restrict the movement of its contained granules. Its exterior is somewhat adhesive so that surfaces or particles coming in contact with it are liable to become attached thereto. Some phenomena observed lend countenance to a theory that this membrane is dotted with minute pores, which permit delicate threads of the soft protoplasm to be extruded, and whose edges, if the projection still continues, during the amoeboid movement, are carried outwards as a sheath to all except the extreme point of the narrow tongue-like process. The material, occupying the space between the capsule and the nucleus, denominated the protoplasm of the cell (the fibroplastin of Prof. Heynsius) is a soft jelly-like matter, in which the power of amoeboid motion resides. It appears to be soluble in water, and saline solutions in all proportions, and when freely diluted loses its amoeboid power, which however is regained in a majority of cases when the excess of fluid is withdrawn."

In support of this view of its structure he observed:—

"I think the surprising rotary motion noticed after the action of ferrocyanide of potassium solution, as described in exp. 6, is even more conclusive; for it appears almost incredible that molecules and nuclei could revolve so quickly unless they floated in a fluid of low specific gravity, or again, that a cell made up of liquid so rare as to permit particles to move through it with such velocity, could either restrict them within its borders or retain its oval state, except by the aid of a cell wall of considerable firmness. To recur to a simile which I have already used in reference to the red blood-disc, it seems to me that this hasty rotation of all the contents within a white blood-corpucle, furnishes the same kind of proof in regard to its parietes, as the swimming of a shoal of little goldfish around the inner surface of their vase affords us first—that they move in liquid and are not embedded in jelly; and secondly, that they are confined by a boundary wall which is strong enough not only to prevent them from passing beyond its limits, but also to preserve its shape in spite of the pressure of fluid within its cavity.

"The laws by which leucocytes take up and part with liquids seem to be simply those of the dialysis of fluids through animal membranes by endosmosis and exosmosis, as studied by Graham on a larger scale in 1855; the rapid inward current from the rarer solution of higher diffusive power, through the cell wall, distending that membrane, and diluting its contents, until an equilibrium of the endosmotic and exosmotic flow is attained, or the capsule is burst by the centrifugal pressure of the accumulated fluid.

"In regard to the motion of granules within the salivary and pus corpuscles, my experiments so fully and uniformly corroborate each other, that, reluctant as I am to dispute the observations of such celebrated histologists as Stricker and Pflüger, I cannot but think that no essential difference exists

in the effects of salt solutions of various strengths upon the leucocytes of saliva, pus, and blood; and from this circumstance, in conjunction with the interesting fact discovered in exp. 5, that the salivary globules, when acted upon by the denser saline liquid, contract to the size of the white blood-corpucle and manifest like amoeboid movements, I conclude that my theory—that the corpuscles of the saliva are 'migrating' white blood-globules which, wandering out into the oral cavity, have simply become distended by the endosmosis of the rarer fluids in which they float (see "Handbook of Medical Microscopy," p. 164)—may now be considered as established upon a firm experimental basis."

The practical deductions drawn were that, "in the first place, the magnitude of the leucocytes in a neutral fluid of known composition, such, for example, as the renal secretion, affords us a useful index to its specific gravity; and, in the second place, the prompt rupture and destruction of white blood-corpucle when acted on by water suggests that in all surgical operations a three-fourths of one per cent. salt solution (54.6 grains to the pint) would have a much less disturbing influence upon the tissues washed or sponged with it than pure water. Lastly," he remarked, "I trust that further investigation of the revolving movements sometimes (not always) produced by solution of ferrocyanide of potassium in the white blood-corpucle may throw some light upon the curious rotary motion of granules in the cells of plants, which has for a long time been deemed inexplicable, and by a late writer is attributed to the presence of supposed cilia upon the inner surface of the cell-wall."

URANOPLASTY.

Dr. J. Solis Cohen, of Philadelphia, exhibited a patient upon whom he had successfully operated, a few months since, for the closure of an enormous cleft in both hard and soft palate, by a modified method, completed in a single operation. The patient was a young girl, some 16 years of age, in perfect health. The cleft was congenital, one and five-eighths inches in length, and seven-eighths in its broadest diameter, and permitted a free view of the entire glandular tissue of the vault of the pharynx, and of the whole of the pharyngeal extremities of the Eustachian tubes. The operation had been performed by the speaker and Dr. Packard, in a sort of surgical duet, a method which they had found convenient and expeditious in a previous operation. At that time Dr. Cohen had proposed to split the edges of the palate, instead of paring them, but had been dissuaded from the attempt by his associate, in view of the callousness of the edges. In the present instance he had determined to split the edges of the hard palate, instead of making the usual incision along the cleft, thus raising the entire flap from the surface of the bone, and saving a loss of one-eighth inch of material. Dr. Packard immediately proposed continuing the slit into the soft palate also, instead of paring it; and the operation was performed in this way, each gentleman operating on one side. The patient being etherised, the New York mouth-gag was introduced, and the operation expeditiously performed in the following manner:—The edges of the cleft being split lengthwise by a shallow incision, the flap of mucous membrane and periosteum was raised from the hard palate, according to the method of Langenbeck, the blunt and angular rasp, used to detach the periosteum, coming into the cleft through the slits in its edges. A double cutting-knife was introduced into the soft palate, just below the line of incision in the hard palate, and the muscles of the palate, after the method of Pollock, by raising and lowering the handle of the knife, and thus sawing with its blade, so as to leave an anterior wound no larger than the blade of the knife. The parts were brought together by several points of wire suture, Langenbeck's needle being used in uniting the flaps from the hard palate, and a semicircular needle, in Schwerdt's forceps, being used for the more moveable soft palate. The fine sutures in the hard and soft palate were clamped by a shot on either side of the cleft; the two in the uvula and lowermost portion of the soft palate were clamped by a single shot respectively.

The operation was a marked success, as exhibited by the examination of the patient. Hæmorrhage from the denuded bone took place on the first and second days, and was checked by pledgets of lint, saturated in Monsel's solution. These were removed in a day or two, and the parts beneath were granulating nicely. The patient was nourished by feeding her from a spoon. Two or three sutures were removed on the third day; the central suture cut out on the fourth day, leaving a gap comprising the space between the adjacent sutures

and the others were removed at intervals, the last suture being removed on the eighth day. Recovery was prompt, but there remained an irregular opening in the centre of the line of junction, the size of the end of a lead-pencil. This gradually contracted, without interference, and at present there was no sign of an opening, and only a depression at that place no larger than the point of a pin.

The points to which Dr. Cohen called attention were these:—The benefit gained in this instance by splitting the edges instead of paring them, and thus saving loss of tissue; and the proof that nature is sometimes adequate to close an aperture in the line of union, without interference from knife or caustic.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 10, 1872.

THE HARVEIAN ORATION.

Dr. A. FARRE, as might have been anticipated, devoted his oration to a subject on which he has a right to speak with some authority. Nor was it by any means difficult for him to do so, considering Harvey had written the celebrated "Exercises on Generation," which would have given him a very high position had not that work been overshadowed by the fame of his other scientific discoveries and pursuits.

On the 26th June, 1657, Harvey was buried, and his "Exercises" are all that remain to us of his investigations on generation, and they have all long been known to be imperfect, inasmuch as he himself lamented the loss during the civil war of some of his most valued treasures in reference to this investigation.

If it is almost impossible to do justice to Dr. Farre's oration, it is an easy task to avail ourselves of it to give a few remarks on the subject, and to express a hope that the whole may be published with such additions as the learned writer may think well to make.

In order to understand Harvey's position it is desirable

to bear in mind the prevalent physiological doctrines of his day. According to Aristotle, the principles of generation were the male and female, she contributing the matter, he the form: immediately after conception the vital principle, and the first particle of the future foetus—namely, the heart, in animals having red blood—being formed out of the secretions of the uterus. The followers of Galen, however, taught that the semen of both parents alike, combined, furnished the offspring, which resembled one or other according as this or that predominated, and that by virtue of such predominance it became either male or female.

Neither of these doctrines satisfied Harvey. "That they are erroneous and hasty conclusions," he says, "is easily made to appear: like phantoms of darkness they suddenly vanish before the light of anatomical inquiry."

Harvey assigned to himself the path of direct observation, as the only one which could satisfy him. In what way, and by what reflections, he intended to sweeten his labour, appears further from passages in his writings in which he has recorded his thoughts in language so illustrative of his own mind and character that the Orator rightly cited them. Among them is the following:—

"Nor is there any just cause wherefore the labour should deter any one, and neither indeed would the way I propose be felt so barren and lonely, but for the custom or vice, of the age we live in, when men, inclined to idleness, prefer going wrong with the many to becoming wise with the few, through dint of toil and outlay of money. And truly in such pursuits it is sweet not merely to toil, but even to grow weary, when the pains of discovering are amply compensated by the pleasures of discovery. It were disgraceful, therefore, with this most spacious and admirable realm of nature before us, and where the reward ever exceeds the promise, did we take the reports of others upon trust, and go on coining crude problems out of these, and on them hanging knotty and captious and petty disputations. Nature is herself to be addressed; the paths she shows us are to be boldly trodden for thus, and whilst we consult our proper senses, from inferior advancing to superior levels, shall we penetrate at length into the heart of her mystery."

The scope and design of Harvey's great work on generation were skilfully displayed by Dr. Farre, and may be briefly stated. Harvey commences his work on the generation of animals with the study of the egg. After explaining what he understands by an egg, he proceeds to select two examples which are marked out for special investigation. The egg of the common fowl being readily obtainable, and admitting of comparatively easy observation, was selected as Harvey's first study. But this particular path had been already trodden by two previous observers, viz., Aristotle among the ancients, and Fabricius of Aquapendente among more recent authors. Harvey set to work to supply what appeared to be wanting in the observations of these authors. Sixty-two exercises are on this special object. His second example was from the viviparous class; first pointing out the artificial nature of the distinction between oviparous and viviparous reproduction. He says all animals whatsoever, in a certain sense, proceed from ova, and are entitled respectively oviparous and viviparous, rather in respect of their mode of bringing forth than their first formation.

Harvey had advantages which neither of his predecessors possessed; for the King placed at his disposal the

costly occupants of the Royal Parks, and from these he was permitted to select as many examples as might serve his purpose. Of this privilege Harvey fully availed himself; and to this opportunity we are indebted for his valuable and original observations on the gestation of the hind and doe. Interwoven with these observations, we find constant reference to the doctrines of Aristotle and Fabricius, together with occasional quotations of the opinions of others; and when to these are added the speculations of Harvey himself, which we find scattered through every portion not only of the exercises but also of the four additional essays with which the work concludes, we shall have enumerated the leading features of Harvey's remarkable and most interesting treatise. "Remarkable and most interesting it may well be termed," said Dr. Farre, "when we consider the circumstances under which its composition was attempted; for scarcely were any of the facts yet discovered upon which a consistent theory of generation might be based. Not one, indeed, of the main points which constitute the foundation of our present views regarding the physiology of this subject, had yet been ascertained. A long interval had still to be bridged over before the first of these elementary facts was fully established. And when now, looking back upon the past, we see with what persevering industry, and by what a long series of observation, conducted by many fellow-labourers, or rather by many labourers working in the same direction, the knowledge which we now possess has been gradually and slowly acquired, and contrast this with the comparative ignorance—it might almost be said the absolute darkness—which prevails in Harvey's day, we may well contemplate with admiration the courage and energy of the man who, in the face of such difficulties, could assign to himself the task of composing a systematic work on the subject of generation."

The Orator next pointed out that the microscope, the most important instrument of research now possessed by physiologists, was at this period practically unknown. Down to a period ten years later than Harvey's death, when the discovery of the spermatozoa was first announced by Leeuwenhoek, the microscope was so little known, and, even when known at all, existed in such an imperfect form, that Leeuwenhoek found it necessary to construct with his own hands not only the lenses, but even the framework of the very primitive instruments with which he conducted his observations.

With reference to Harvey's original design the Orator observed that his observations were not limited to the vertebrate series, from which he had selected the two typical examples just named, but were also extended to the invertebrates. This he gathers from passages occurring in his work; more particularly from the statement which he made to Ent as one ground of objection against parting with his papers—namely, that they must be held to be imperfect, as not containing his investigations on the generation of insects—a class which is second to none in the whole range of the animal kingdom for the information which it affords in the study of this process. Harvey seems to have bestowed much care upon these, and his distress at the loss of them was correspondingly great. As Aubrey describes it, "they contained many curious observations; but these, together with his goods at his lodgings at Whitehall, were plundered at the beginning of the Rebellion; and he often said that, of all the losses he sustained, no grief was so crucifying to him as the loss of these

papers, which for love or money he could never retrieve or obtain." This, indeed, is the only point upon which we find throughout Harvey's exercises, any expressions of this kind uttered by himself. Something in the course of his observations having occurred to him, upon which he desired to get further information, he refers to the circumstance noticed by Aubrey in the following touching expressions. "Whilst I speak of those matters, let gentle minds forgive me if, recalling the irreparable injuries I have suffered, I here give vent to a sigh. This is the cause of my sorrow. During our late troubles, and more than civil wars, certain rapacious hands stripped not only my house of all its furniture, but, what is subject of far greater regret with me, my enemies abstracted from my museum the fruits of many years' toil; whence it has come to pass that many observations, particularly on the generation of insects, have perished." These regrets of the great master may well inspire us with additional desire to honour his memory, and this could not have been better done than in the Oration for 1872.

GOING SNACKS.

A CORRESPONDENT of the *Pharmaceutical Journal* has, in its last issue, called attention, by a forcible and reasonable letter of complaint, to a practice which we are aware is daily on the increase within the ranks of the Profession, and which ought to be discouraged as being unfair to the patient and discreditable to the Profession. Long since the system of "going snacks" between certain practitioners and their pet apothecaries has been exposed and condemned in these columns, and we now revert to the subject because we are forced to believe that the disreputable traffic which we then censured as being practised by semi-legitimate, semi-quack practitioners is now carried on publicly by members of the Profession whose rank gives a new importance to the system. The charge which is made by the correspondent of the *Pharmaceutical Journal* is, that "Medical men who have practice and reputation" are parties to a corrupt agreement with some special apothecary, under which compact the practitioner, by rendering his prescriptions unintelligible to those dispensers who do not possess the private key to their comprehension, compels his patients to get the prescription compounded by the apothecary who is party to the suit and, the writer assumes, goes snacks with the apothecary in profits and benefits. He says—

"I know that the practice is not carried on by 'ignorant' Medical practitioners, but by some who have a practice and reputation, as well as social position, which ought to be far above such miserable contrivances. What would 'G. H.' think were he to receive such prescriptions as the following?—"Ung. flav.," "Pil. Asiaticæ," "Locio Oculi," "Lin. Co.," "Ung. Rub.," "Acid. Tonic. No. 2," "Pil. Nucis Co.," "Tinct. Alteratives," &c. Yet these are but specimens of what have gone through my hands since I became connected with the drug business. I have frequently sent to the physicians for explanations, but instead of finding the prescription coming into the shop in a more extended and comprehensible form, have been horrified at the reply that these could only be got at so-and-so's establishment. This system of secret or tacit understandings between physician and pharmacist ought to be most strenuously opposed by all right-minded members of the trade. I would far rather have surgeon-druggists for my neighbours than such underhand dealers. I know some, however, who

have gone into this system, and who would give a good deal now to get rid of it altogether; for they have discovered to their chagrin that the benefit is all on one side, viz., that of the Medical practitioners. They have found out that unless they are dishonest by making an extortionate charge for dispensing and withholding the prescription, which they have no right to do, they are simply playing a game at filling the exchequer of the doctor, while they are preventing the money reaching its legitimate source, viz., their own pockets and those of their brother pharmacists."

We believe, if we could know the exact terms of such understandings, we should find the inuendo that a direct percentage on the cost of the medicine is paid to the prescriber to be false, but we believe that the *quid pro quo* received of the practitioner is the no less direct bribe of frequent consultations, and that thus the profits of compounding are thrown into the pockets of those apothecary practitioners who have most consultations to give. The sense of honour of the Profession at large cannot fail to condemn such practices, which are a secret and disreputable means of putting into the prescriber's pocket money to which he has no earthly claim. The surgeon or physician sells his advice and nothing more, and when he has given that commodity and received his fee he has no equitable right whatever to force his patient to pay him a second fee in the form of a percentage for the means of carrying out that advice.

We cannot think that a secret treaty of this sort can be, even in a monetary sense, profitable to either party, and we should advise the dispensers who suffer to take means to render it impossible. No practitioner could carry on such a trade if his patients were aware of the object of the compact, and once the secrecy of the understanding is destroyed we shall have an end to this most disreputable system.

SURGERY OF THE FRANCO-GERMAN WAR.

(Continued from page 8.)

VI.

A naval lieutenant was wounded late in the night of the 12th January, a shell having penetrated a casemate where he was lying asleep, a heavy beam fell upon both his legs, fracturing both his legs, the left in two places, with laceration of the soft parts, the right simply of both bones, the left elbow at the same time contused. When brought to the ambulance, twelve hours after the injury, there was considerable swelling of both legs, especially the left, it being also shortened to some extent. Extension and counter-extension being practised, the fractured portions were placed in apposition, the limb placed in a *gouttiere*, and submitted to cold irrigation during four days. The right leg was immobilised in two metallic *gouttiere*. Febrile reaction set in on the 16th, with violent disturbance of the system, severe pains in both legs, swelling, much delirium, and rapid pulse, these being treated by the administration of aconite. On the succeeding days free suppuration took place from the left leg, but the fever was less. On the 21st a dextrine bandage was applied to the right leg, but the pus, which discharged from the left was observed to have an infected odour, deep suppuration extending also around the seat of the injured wound. At this time the patient was treated with quinquina and aconite. On the 25th hæmorrhage, to a great extent, and of arterial blood took place from the wound, requiring the application of pressure by tourniquet and digital to the femoral artery, a roller of duty among the attendants being established for the purpose. Hæmorrhage did not recur, but on the 26th the

odour of the discharge was very offensive, the pulse 100, and very small, the patient voiding his stools involuntarily. On each of the succeeding days an attack of shivering came on, followed by some fever; the patient was evidently sinking, and on the 31st he died *pyæmic*.

A marine apprentice was wounded on 13th January, 1871, by a fragment of shell, causing a fracture of the right tibia, with fracture of the fourth and fifth metatarsal bone of the left foot. The tibia was fractured about four finger breadths below the condyles. The limb was placed in a *gouttiere*, and submitted during three days to cold irrigation. The solvent dressings were applied to the left foot. The progress of the case was satisfactory, and on 19th February, when the last report was made, the cure was advancing favourably.

A *chef de piece* was wounded on 19th January by the explosion of a shell, the injuries inflicted including a wound on the inner surface of the right thigh at its middle part, but without fracture of the femur, two similar ones in the calf of the left leg, and two others on the left foot; but none of them of seeming severity, nor implicating the bones. The progress of this case was for some days favourable; suppuration from the several wounds good, and cicatrisation advancing. On the 7th of February, however, the patient was seized with violent shivering, followed by fever, for which he was treated with quinine and aconite. On the 9th the wounds on the right leg assumed a *scorbutic* tint; those on the left had already healed. On the evening of that day violent shivering recurred, succeeded by high pyæmia and severe pain in the region of the liver. The occurrence of *pyæmia* was apparent. On the 10th the hepatic pain increased; the skin had assumed a jaundiced hue; he had diarrhœa, and suffered, moreover, from muscular spasms. Quinine in various forms was administered, but the progress of the symptoms was from bad to worse; he gradually sank, and on the 11th he died.

General Principles of Treatment.—The order of procedure in cases of wounds was somewhat as follows:—A careful examination of the extent of injury being made, all foreign bodies and loose fragments were extracted; the limb placed in position, being put into a *gouttiere* and immobilised, subjected to irrigation with cold water during several days, care being, at the same time taken, that the bedding or person of the patient should not be wetted by the process, for which purpose the form of *gouttiere* invented by Dr. Carof was that used. The attempts at conservation of the limbs were practised to the very last limits—so much so, that in about 100 cases of wounds admitted, an operation was only performed in two, namely, one disarticulation at the shoulder, and one excision of the head of the humerus. Even in penetrating wounds of the knee joint, and in fractures of the bones in its vicinity, the same method was followed, and, as will be seen by the statistics and reports of individual cases, with a considerable measure of success. Unhappily, the rate of mortality among the wounded was high. Towards the end of the siege, notwithstanding all hygienic precautions, *pyæmia* occurred, as indeed it did everywhere that considerable numbers of wounded were collected together. This affection attacked the patients whose injuries were comparatively slight, as well as those more severely wounded, and, in some cases were those in whom no injury of the bones existed. With regard to wounds of the trunk, head, and those of the limbs without fracture, they were dressed with glycerine and cataplasms; afterwards with diluted alcohol, aromatic wine, water containing carbolic acid, coal-tar soap, ointment of styrax, powder of camphor, quinine and charcoal. All the dressings were prepared by the surgeons. The patients were fed as liberally as the circumstances of the siege admitted; and, although they were unfavourable, it is a source of consolation to know that so many limbs were preserved that would in former days have been amputated.

Ambulance Organisation.—Baron Mundy, of Vienna, early in September, 1870, set on foot an ambulance or temporary hospital in the palace of the Corps Législatif.

He continued throughout the entire siege to act as Director of the establishment, the professional details being conducted by Professor Moesetig, also of Vienna; under these two eminent members of our Profession the ambulance was alike noted for the success of its administration and the fortunate results as regards the wounded treated in it. When the insurrection of the Commune took place, Baron Mundy set to work to establish an ambulance at St. Cloud; and, taking advantage of his past experience during the Prussian siege, he would appear to have placed his latter establishment upon so complete a footing as to render it in many respects a model for any other that may hereafter have to be formed. Professor Moesetig, it may be remarked, had returned to Austria, but his place was taken by Dr. Arendrup, of Copenhagen, a young surgeon of very great promise, whose life was sacrificed in the ambulance now about to be described.

I. Locality and Personnel.—The ambulance, situated near the basin of the Grande-gerbe in the park of St. Cloud, comprises—8 huts, for 25 beds each—200 beds; 1 tent used as a chapel; 1 cottage for the direction and administration; 3 huts for Medical officers; 1 hut for operations; 1 hut for medicines, instruments, and surgical appliances; 1 hut as a mortuary; 4 huts for the sisters; 2 tents and 2 huts for the infirmiers; 1 hut as a kitchen; 2 parlours as dining-rooms; 1 ice-house; 2 huts for linen and stores; 2 hut magazines for arms and equipment; 2 rooms for superintendents; 1 shed for soiled linen; 1 shed for fuel; 1 stable; 1 shed for carriages and fire-engines; 40 lamps and shades for walls; 2 bell stands; 1 shed for dry earth for closets; 30 closets and urinals; 2 water troughs; 4 trenches for night soil.

The *personnel* of the ambulance consists of—1 principal Medical officer as director; 4 surgeons; 4 assistant-surgeons; 1 almoner; 1 purveyor; 1 assistant-purveyor; 18 sisters of mercy; 1 steward; 1 lady superintendent of the laundry; 1 head infirmier; 16 hospital attendants; 1 park-storekeeper; 2 cooks; 1 under cook; 2 washerwomen; 2 men in charge of window blinds, curtains, &c.; 3 firemen; 2 night watchmen; 2 day superintendents; 3 coachmen for three carriages of two horses each; 2 lamp-lighters; 3 sweepers; 2 men in charge of closets, &c.; 5 fatigue men for the different services.

II. Responsibility.—The Medical Director is alone responsible for everything in connection with the medico-chirurgical services, hygienic and dietetic; with the administration, the discipline, the treatment and condition of the wounded; and with the general control of all the services of the *personnel*. With regard to the medico-chirurgical treatment of the wounded, the surgeons-in-chief share that responsibility.

The above-named officers have alone the right of giving orders to the auxiliary *personnel*, who are subordinate to them; and the *personnel* have the right of appealing to the Medical Director of the ambulance against any instruction not emanating from him.

All strangers to the ambulance are requested not to interfere with any of the branches of the service.

The responsibility and position of the Director with respect to the Société de Secours aux Blessés are regulated between the two parties by special arrangements, upon which the Director has based for the most part the articles for the regulation of the ambulance.

III. Divine Service and other Religious Ceremonies.—Divine service takes place on Sundays and Fêtes at 7:30 a.m. Its duration is limited to twenty minutes.

When a wounded man shall request religious assistance, information must be given to the *almoner*, and at the same time to the Medical officers when the wounded man desires the administration of the Sacrament. In the case of men severely wounded, of those in danger of death, the Medical officers will have to determine the proper moment for the assistance of the *almoner* or for the administration of the Communion.

Matins and vespers are performed by the sisters, with

due regard to the repose of the wounded. Freedom of worship and conscience remains in force.

Considering that the Société de Secours aux Blessés des Armées has established their ambulance, that it maintains it at its own expense, without shrinking from any sacrifice in order to render the wounded every possible assistance and care, it is becoming that in vespers prosperity to this establishment of beneficence and public utility should be specially solicited from Heaven, as well as for the donors to whom this society is morally responsible.

IV. Reception and Discharge of the Wounded.—The Medical Director of the ambulance has the sole right of ordering the transfer of the wounded to other hospitals, and their final discharge.

He will personally inspect the condition of the ambulances and the medico-chirurgical and alimentary resources which are at their disposal.

The surgeons, and in their absence the assistant-surgeons (under the instructions they shall have received), alone can receive wounded in the ambulance.

They also shall determine in which hospitals and in which beds the wounded are to be placed.

V. Arms, Belts, Knapsacks, and other General Military Equipment.—Whatever may be brought in with the wounded, arms or other equipment, shall be taken to the dépôt by the storeman of arms, who is specially charged to make out a detailed list of them. He will forward this list to the paymaster.

Firearms shall be immediately discharged, and placed in store, as well as all other arms and equipment, in the State dépôt for arms set apart for this purpose.

With regard to clothing, the storekeeper will take care to deposit them in a proper state of cleanliness, and to keep them in store, to be returned when necessary to the wounded, either before their departure or when they are discharged from the ambulance, and in case of death to the military hospital for that purpose.

VI. Permission to enter and leave the ambulance during day or night is accorded only to officials, to the Medical officers, paymaster, steward, to the sisters, the infirmiers, the *personnel* of the kitchen, of the ice-house, and stores; to the lamp-men, and in general to the *personnel* already enumerated in the earlier part of these regulations.

The ambulance is surrounded by a white fence, which it is forbidden to cross under the penalties set forth by the law.

The surgeons have the sole right to authorise the parents and friends of the wounded to visit them in the ambulance.

Except in special cases, visitors are admitted daily between two and five in the afternoon.

Entry and exit are only permitted by the gates marked "In" and "Out," and under the conditions of the regulations.

Valid information on the sanitary state of the wounded can only be furnished by the surgeons.

It is absolutely forbidden to uncover the wounded, to examine their wounds, or to touch the dressings. Surgeons and hospital assistants only have the right of acting thus.

Visitors, infirmiers, and all others, except the wounded, are strictly prohibited from smoking in the ambulance.

When the ambulance is visited by an official personage, or any person of distinction, or of the Medical Profession, the sisters or infirmiers will inform the surgeons, or, in their absence, the paymaster or steward.

Entry to the quarters of the officers is permitted to those foreigners who shall be authorised by the surgeons.

The Medical Director is entrusted with the power of granting leave beyond the ambulance; and in his absence, the officer who fills his place.

The watchword of the post situated by the Orleans gate, that of the porter, having reference to the entry to and exit from the ambulance, as well as the superintendence of the park which surrounds the buildings, the measures relative to the heating, lighting, to the precautions

to be taken against fire, to the supply of water, the cleanliness of the surroundings and exterior of the ambulance,—are subject to orders determined by the commanding officer of Engineers attached to the camp, and the director of the ambulance.

Notes on Current Topics.

Inhalations in Chronic Diseases of the Respiratory Organs.

DR. HOLCOMBE (*U. S. Med. and Surg. Journal*), in his review of the work "On Chronic Diseases of the Respiratory Organs," by John Meyhoffer, M.D., states that this author is a strong advocate for the inhalation of specific medicines, including warm salt water. He approves the inhalation of carbonic acid gas diffused in an atmosphere softened by watery vapour, for which special pneumatic chambers have been built at some of the European springs. He commends it especially in bronchorrhœa with dilatation of the air-tubes and obstruction of the finer bronchial divisions with mucus, in the belief that the carbonic acid powerfully strengthens and prolongs the expiratory effort.

For syphilitic laryngitis, Meyhoffer commends the recent practice of injecting minute portions of bichloride of mercury into the cellular tissue. It is so painful, however, that morphine should be added to the solution. The same author recommends the use of selienate soda in tubercular laryngitis. He says, further, that there are two great types of the scrofulous diathesis, the *irritable* and the *torpid*. The first is lean, slender, thin skinned, with great vascular and nervous excitability, and will be improved by use of cod-liver oil. The torpid class have fatty, puffy, leuco-phlegmatic forms, and will be made worse by the use of an oleaginous remedy.

A New Theory of Asthma.

In the sputa of asthma, also in the sputum of patients who have died with leukemia, certain colourless, octohedral crystals have been observed, says the editor of the *Pacific Medical Journal*, by European microscopists. Some of the crystals are large enough to be detected by the naked eye. Professor Leyden, of Königsberg, as appears from an extract from *Virchow's Archives*, in the *Philadelphia Medical Times*, regards them as the cause of the bronchial spasm in asthma. He advises asthmatic patients to inhale a solution of common salt and carbonate of soda, for the purpose of dissolving the crystals and preventing their formation.

Novel Treatment of Croup.

DR. F. W. BARTLETT, in the *Buffalo Med. and Surg. Journ.* for April, reports a number of cases of diphtheritic croup successfully treated by the method described in the following extract: The patient, a boy of three years, a child of Mr. R. then living on Elk street near the bridge, had been treated for several days by an excellent medical friend who kindly attended my patients at a time of great affliction in my family. An elder child had died the week before of so-called pseudo-membranous croup, and the patient was under the usual treatment for that affection. On examination I felt satisfied the case was one of diphtheritic croup, which had progressed to a stage when the

most active treatment was required to give any prospect of success. A few moments' consultation and the treatment in the case was discontinued, and the usual tonic treatment for diphtheria substituted with the following local treatment: A blister, size of a silver half dollar, was at once applied to the nucha, a tin tube ten inches in length and one-third of an inch in diameter, similar to the blow-gun in use by boys, was procured from a neighbouring tin-shop, and the fourth part of a teaspoonful of common salt dried and powdered was forcibly blown into the fauces. The disturbance was less than I had ventured to hope. There was scarcely any cough, a little clearing of the throat and expulsion of several teaspoonfuls of yellowish mucous was the only excitement produced. In four hours I called again and repeated the application with similar results, and with apparent relief to the breathing which had been performed with great difficulty. Direction was then given to the mother to apply from one-fourth to one-third of a teaspoonful every three hours till my next visit. Twelve hours had elapsed when I called again to find the blister formed and commencing to discharge. The respiration had improved, medicine and nourishment had been well borne. The case progressed most favourably, the blister discharging freely and giving but little discomfort to the child. On the sixth day a second blister was applied over the epigastrium which simply furnished a dry red surface, no exudation appearing. By the twelfth day the croupal sound had disappeared and the voice was quite restored and ultimately permanently so.

Dr. Felix Roubaud on Tobacco-Smoking.

In a letter addressed to M. Jules Guérin, President of the "Association Contre l'abus du tabac et des boissons alcooliques," Dr. Roubaud, after remarking that many men smoke from morning to evening without their intellectual faculties being thereby deranged, observes that he does not contest the evil influence of the abuse of tobacco (*La France Méd.*, 15th June). It is said, he remarks, by some that tobacco smoke has an injurious effect on the intellect, because from 1818 to 1830 the revenue on tobacco produced 28 millions, and there were then 8,000 insane; whereas, in 1842, the revenue from tobacco was 80 millions, and there were 15,000 insane; and in 1862 there were 40,000 insane, and the revenue from tobacco was 180 millions of francs. But he demurs to the conclusion that there is cause and effect to be noticed here. Certainly, Chateaubriand, Lamartine, Victor Hugo, A. Dumas, Michelet, and Thiers, were no smokers; but many great men have smoked. What he wishes, however, to point out is, that smoking dries up the mucous membrane of the fauces and tempts men to drink. This is one of the chief accusations he makes against tobacco. Absinthe is most dangerous, and is largely consumed by smokers. It is much to be desired that abuse of smoking were as much attended to in England as it now is elsewhere.

The Medical Examining Board for England.

THE Vice-Chancellor and Proctors have nominated H. W. Acland, Regius Professor of Medicine, and G. Rolleston, M.D., Linacre Professor of Physiology, to represent the University of Oxford on the Committee of Reference for the Medical Examining Board for England, in virtue of the power granted by the decree of June 4, 1872.

Intestinal Erectile Tumours.

DR. LABOULBENE remarks that erectile tumours have been observed on nearly all parts of the skin, on the orifices of mucous membranes, and in several viscera; but no case of erectile tumour of the stomach or intestine has ever, so far as he knows, been recorded.

He has put the existence of such tumours beyond doubt by a recent communication to the Paris Academy. In the case related by him, the seat of the lesion had been diagnosed by the symptoms, and the forecast was corroborated by the subsequent examination, which discovered a spontaneously-ulcerated tumour of the duodenum.

The author draws the following conclusions:—

1. Erectile tumours (angioma) exist in the intestinal canal as well as the external tegumentary surface.
2. Such tumours are developed on the intestinal mucous membrane.
3. They may give rise to fatal hæmorrhage.

Tannate and Sulphate of Quinine.

THE question of the activity of the former salt has recently been discussed in the Academy of Medicine of Paris, Messrs. Chanfard, Briquet, and others thinking that it is without activity; and M. Mialhe, speaking of the sulphate of quinine, makes the following observation, which is worthy of attention:—

Sulphate of quinine should never be employed as a basic sulphate, but as an acid salt. In this state the sulphate may compete with all other salts the base of which is quinine; for it should be noticed that it is the quinine itself, and not its saline combinations, which is active. The acid serves only as a vehicle for the introduction of the quinine into the blood, where it is set free by means of the alkaline, or earthy bicarbonates which the blood contains, and then its therapeutic action begins. It is a mistake to believe that the sulphate of quinine, when the salt is administered, can be traced in the urine; the salts traced are the acid phosphates of quinine associated with the phosphates of lime and magnesia.

Ambrose Pare.

DR. CHASSY thus speaks of Pare in an address at the University of Michigan, at the beginning of the sixteenth century, there was in the town of Laval, in France, an honest trunk-maker who had a son. He apprenticed him to a barber surgeon. The son, thoroughly enthused with his work, left his humble teacher and made his way to Paris. He was poor, he had few books, and only the most obscure, inexpensive teachers. But he had what was far better, an undying enthusiasm, an unremitting devotion to his work. In 1536, this obscure young doctor followed the French army into Italy. He had common sense, he had courage. He did not hesitate to attack the barbaric surgery of the time, he kept boiling oil away from wounds, and he was not afraid of cold water. His results were deemed miraculous. Returning to Paris in 1539, the unknown young doctor of three years before found himself famous, and was received with the highest honours by the Royal College of Chirurgeons. On the renewal of the war he interdicted the application of red-hot irons to bleeding vessels, and demonstrated the efficiency of the ligature. He knew nothing of Latin, the *sine qua non* of an educated man in that day, yet venerable universities showered

degrees upon him. He wrote most creditably on surgical topics. He was the friend of kings, was king's surgeon to Charles IX. and Henry III., and attended Francis II. on his death-bed. And this was the romance of a poor young man, the romance of a life of unremitting, enthusiastic work. The name of this poor young man was Ambrose Pare a name we still delight to honour.

Mortality Statistics of the Three Learned Professions in America.

DR. J. M. TONER having had an opportunity to examine some of the advance sheets of the forthcoming U. S. Census Report for 1870, has compiled statements of the number of deaths returned as occurring among the three learned professions in America— theology, medicine, and law—for the year ending June 30, 1870.

For the year 1850 there were returned 28,842 clergymen; 40,564 physicians; and 23,939 lawyers. For the year 1860 there were returned 37,529 clergymen; 54,543 physicians; and 33,193 lawyers.

It is perhaps fair to presume that each retains about the same proportion to each other in the census of 1870.

The following is the number of deaths reported among clergymen, physicians, and lawyers in each State and Territory of the United States for 1870, as reported by Dr. Toner in the *Boston Medical and Surgical Journal*:—

	C.	P.	L.		C.	P.	L.
Alabama	19	30	14	Nebraska	2	1	2
Arkansas	2	11	9	Nevada		1	2
California	17	23	29	New Hamp.	10	20	10
Colorado		4	3	New Jersey	15	20	13
Connecticut	10	14	9	New Mexico			1
Delaware	4		1	New York	74	136	114
Dist. Columbia		1	6	New Carolina	16	15	10
Florida	7	4	5	Ohio	46	66	31
Georgia	15	30	12	Oregon		3	5

AN agitation is on foot for the purpose of again enforcing the Mayne Law for muzzling dogs during the hot weather, several persons having recently been bitten by dogs supposed to be insane.

Renal Calculi the Cause of Screaming-Fits in Infants.

At a late meeting of the New York Pathological Society, Dr. Jacobi said that the frequency with which stones were found in the kidneys of new-born infants would lead to the conclusion that the origin of calculi was, if not congenital, confined to the earlier weeks of infancy. In forty *post-mortems* upon children under six months, male in succession, there were calculi in the kidney in six. He remarked that the violent screaming-fits met with in young infants could often be accounted for on the supposition of the passage of a renal calculus. He had met with two such cases; one he had known to have had several of such screaming-fits, and in the other the stone was cut out and was found to have a very large nucleus of uric acid, pointing most unequivocally to its renal origin.

A VALUABLE appointment is now vacant in Glasgow—that of Sanitary Inspector to the Board. The stipend is £600 per annum; the gentleman appointed being required to devote his whole time to the duties of the office.

LAST week two unfortunate men in the employment of the London and North-Western Railway Company, seeing a liquid, which they mistook for spirits, running through the bottom of the luggage van, caught a quantity in their cans and drank it. One died soon after, and the other lingered on for a short time in fearful agony. The liquid was pure methylated spirit.

THE Dublin Eye and Ear Infirmary established by Dr. Jacob opened its doors last Thursday, and its wards, although the Institution is hardly yet completed, are already occupied. The Infirmary occupies the house in Ely Place, for so many years the residence of Dr. Jacob and his father, and it happens to be, from the extent of its rooms, eminently suited for its new object. It will accommodate eighteen beds, and is open to all cases of eye disease which may be recommended for admission or may present.

WE are much concerned to learn that the latest report of the health of Dr. Rawdon Macnamara is not favourable as we had hoped we should have been able to record. On Thursday last, inasmuch as the fever and local erysipelas appeared to have acquired an intermittent character, it was decided by Dr. Stokes and Mr. Porter that Dr. Macnamara should be removed to Howth. We regret to understand that since that change was made the lung has been seriously involved, and the patient has suffered much pain.

A MEETING of the Fellows of the Royal College of Surgeons in Ireland was held on Thursday last pursuant to charter to elect a Professor to occupy the Chair of Ophthalmic and Aural Surgery, recently created by the Council. According to the prescribed arrangement, seven Councillors—Messrs. Irvine, Ledwich, Carte, Wharton, Elliott, Edward Hamilton, and Kidd—were chosen by lot and duly sworn to elect. Four candidates presented themselves,—Mr. Henry Wilson, Examiner in Ophthalmic Surgery in the University of Dublin and Assistant-Surgeon to St. Mark's Ophthalmic Hospital; Dr. Archi-

bald Hamilton Jacob, formerly Ophthalmic Surgeon to the City of Dublin Hospital, and now Chief Surgeon of the Dublin Infirmary for Diseases of the Eye and Ear; Dr. H. Lofie Stoney, late Ophthalmic Surgeon to the Adelaide Hospital, and now Ophthalmic Surgeon to the City of Dublin Hospital; and Dr. Swanzy, Surgeon to the Adelaide and the National Eye and Ear Hospitals.

After a protracted sitting, the selected Councillors declared Dr. Henry Wilson to be elected.

A VERY important and lucrative office—that of Professor of Anatomy and Chirurgery in Trinity College, Dublin—has been advertised as vacant.

It is announced, pursuant to the provisions of the Act 40 Geo. III., that the Professorship will become vacant on October 14th, 1872, and that on October 19th, 1872, the Provost and Senior Fellows at the Board-room of Trinity College, will proceed to elect.

The emoluments and advantages of the Professorship consist in a fixed salary of £200 per annum and of fees of three guineas each payable by each student attending a three months' course of clinical lectures delivered by the Professor in Sir Patrick Dun's Hospital.

The Professor is also entitled to charge reasonable fees to be paid by all persons attending his lectures (other than clinical), such fees to be regulated from time to time by the Provost and Senior Fellows. He is also entitled to a portion of the profits arising from the dissecting school, such proportion being from time to time regulated by the Provost and Senior Fellows.

In addition to the above fixed salary of £200, a further sum of £50 per annum is paid to the Professor in consideration of certain exemptions in the case of Students in Arts having their names on the books of the College.

The Professorship is open to all persons who have taken Medical degrees or have obtained a licence to practise from the King and Queen's College of Physicians in Ireland, in consequence of a testimonial under the seal of Trinity College, Dublin.

By a resolution of the Provost and Senior Fellows, no University Professor in the School of Physic can hold an appointment as Medical Officer to any Clinical Hospital other than that of Sir Patrick Dun.

A preference will be given, *ceteris paribus*, to a candidate who will agree to give up all private practice.

The gross emolument of this Professorship exceeds, we believe, £1,000 a year, and the competition for it will no doubt extend to England and Scotland. The concluding paragraph is very significant, indicating, as it does, that no Dublin surgeon in good practice need apply.

Gleanings

Hypodermic Injection of Quinine.

By Surgeon ODEVAINE, Bhopal Battalion.

AT pages 63 and 64 of the *Indian Medical Gazette* for April, 1871, will be found a few remarks having reference to the above subject.

It there stated that amongst the objections to the indiscriminate use of quinine subcutaneously was the danger of causing tetanus, and related one case of the disease as having occurred in my own practice. I have now to record two more deaths from tetanus, resulting from abscesses produced at the site of injection.

In the first of these, the ordinary sulphate of quinine was used in solution with citric acid, but in the last, neutral or soluble quinine without any free acid was employed.

Both the injections were given by the Jail Hospital native doctor, who states that in the last the quinine was in a perfectly clear solution. An abscess formed at the site of

puncture a few days subsequent to the injection, and both men died within twenty hours from the first appearance of tetanic symptoms.

In the cases in which I have myself employed the neutral quinine, dissolved in distilled water, in the proportion of four grains of the former to forty minims of the latter, no irritation has resulted. I think it but right to make known the fact that tetanus does occasionally occur as a result of the hypodermic use of quinine, and to record my opinion that this medicine should only be employed subcutaneously, when its administration by the mouth or rectum is, owing to great gastric irritability or the presence of diarrhoea, inadmissible.

In dangerous cases of intermittent or remittent fevers, or where it is of importance that the next exacerbation should be checked, we should certainly be justified in using quinine subcutaneously.

It may be said that the occurrence of these three cases of tetanus was a mere coincidence, as this disease is known to arise in some persons from apparently very trivial causes; yet it is very strange, that of the thousands I have vaccinated, and the hundreds who have been blistered, leeches, and operated upon by me, during a practice of seventeen years, none have suffered from tetanus.

Certainly, I have met with several cases of the disease as the result of accidental wounds, and occurring idiopathically; nevertheless, I have formed an opinion that there is something in quinine which may particularly irritate the afferent nerves, or else, that the malarial cachexia itself, in some way, causes a predisposition to tetanus.—*Indian Medical Gazette*.

Syphilis in the Inferior Animals.

By E. ANDREWS, M.D.

(Professor of Principles and Practice of Surgery in Chicago Medical College).

THE distinguished advocate of syphilisation in Paris, Dr. Auzias Turenne, proved, as he supposed, by inoculations, that while the inferior animals could have soft chancre, they were incapable of constitutional syphilis. This conclusion, though resting solely on the narrow basis of one man's experiments, appears to be accepted by all the eminent syphilographers of Europe; and being the prevailing doctrine, I have myself often quoted it as true.

On consulting a number of leading works on Veterinary Surgery, I find no allusion to syphilis except in Gamgee, who doubtfully speaks of certain primary sores, but of no secondary in inferior animals. A veterinary surgeon of this city, however, informs me that he has met three cases of what he considers well marked constitutional syphilis in breeding animals. The first case was that of a bull in England. The first symptom was a chancre on the penis, accompanied with inflammation and swelling, and followed by secondary eruptions on the skin.

Case second was on a celebrated imported bull. The first symptom was a discharge from the prepuce, with swelling and inflammation. This was followed, first by moist ulcers in the mouth, and later by eruptions with large scabs on the skin.

Case third was that of a boar which was supposed to have a primary sore, which was followed by eruptions on the skin. The veterinary surgeon above mentioned says that gonorrhoea is very common in bulls.

These three cases are not enough to bring us to a decisive result, but they show that the subject needs a re-investigation. Domestic animals are certainly less subject to syphilis than men; but they may, after all, have it in a mild and modified form. If experiments should prove the latter hypothesis, the question would immediately arise whether this modified form could be used, like vaccinia, as a prophylactic against syphilis proper. Who will make the experiment?

Lime Inhalation in Croup.

By J. P. MATHEWS, M.D., Carlinville, Ill.

THE inhalation of lime in croup, as suggested to me by my friend, Dr. E. E. Webster, of Carondelet, Mo., has succeeded admirably in several cases. I use it by breaking lumps of fresh lime into pieces as large as eggs, and dropping them one by one into a bucket half full of hot water, which causes ebullition, and from which the child inhales the steam. It should sit upon its nurse's or parent's knee, with a blanket thrown

over both, and inhale the steam until it perspires freely, the pulse becomes weak, and the child presents some symptoms of exhaustion. It should then be wrapped in a dry blanket, and laid on a bed in a room pregnant with the same vapour. This should be repeated every three or four hours, until breathing becomes natural. This may be done independently of any other favourite treatment a physician trying it may choose. I have succeeded with it in several cases of true as well as diphtheritic croup, in which my experience has taught me I should have failed with any other mode. I therefore ask my professional brethren to give it a trial and report their success. I believe it will prove invaluable to many, as it has been to me, in treating this drudged disease.

Transfusion.

It appears to some that the difficulties and dangers of this operation have been exaggerated, a position that is certainly in consonance with the results of injecting saline solutions into the veins. The *Gaz. Med. Ital. Proc. Venet.* published a case of gastric hæmorrhage in a woman sixty-three years of age, who being in *articulo mortis*, was restored by the injection of one and a half ounces of defibrinated blood taken from the arm of her son. In seven days she was discharged cured from the hospital. It is stated that the warming of the blood, or the syringe, and any preparation of the vein more than is necessary for ordinary bleeding, are all useless precautions. Even the mixture of air with the blood is innocuous.

Commenting on this, the *Medical Cosmos* adds that the addition of such diffusible stimulants as ammonia to the blood to be injected not only serve to preserve its fluidity, but also to directly excite the heart and general circulation.

In the *Centralblatt* some cases of transfusion have been published by Juergensen, and extensively quoted. In a case of gastric ulcer, complicated with pleurisy, in which the patient was reduced to the last extremity, the operation was without benefit. Two other patients recovered, one a case of phosphorus poisoning, in which there was much hæmorrhage; the other a case of asphyxia from carbonic acid, in which the benefit was most marked, and for which accident Juergensen looks upon transfusion as an important remedy.

Décaisne on the Treatment of Delirium Tremens.

DÉCAISNE (*Journ. Off. de la Repub. Franc.*, 1871) has made comparative experiments on the different modes of treatment of delirium tremens. He treated five patients with opium and four with digitalis. The symptoms of excitement disappeared under opium on an average of five days, and with other remedies in six days. Seeing the similarity of results obtained with different remedies, Décaisne desired to try expectant treatment, and put eight patients under this treatment; these became calm in about a similar number of days. As a consequence of these experiments, he proposes expectation as a treatment for delirium tremens, with the sole observation that all alcoholic fluids (wine, &c.) be left off, and tepid baths made use of.

The Uvula.

DR. NOBLE SMITH condemns, in the *British Medical Journal*, the practice of snipping the uvula, and advocates its complete removal in cases where any operative procedure is called for. He relates two cases simulating consumption, which were at once cured by the removal of the elongated uvula; and says that, in mere snipping the organ grows again, and no good results. On the other hand, Sir G. D. Gibb argues in the *Lancet*, that the uvula has important functions in deglutition and vocalisation, and that its true muscular end does not often become elongated, but only the membrane, and adipose tissue; consequently, that snipping this part and leaving the muscular fibres intact is quite sufficient, and that no inconvenience arises from this practice.

Obituary.

WILLIAM HENRY SUFFIELD, M.D.

On the 23rd June, at his residence, Letterfrack, Co. Galway, in the 58th year of his age, William Henry Suffield, Esq., M.D., late Medical Officer of the Clifden Union Fever Hospital and Dispensary (a post which he held for 28 years), deeply and deservedly regretted by a large circle of friends, and by those with whom he was professionally acquainted. With him "to live was Christ, and to die was gain."

CUNDURANGO.

We find in the new number of the *Chicago Med. Examiner* a series of letters from South American Surgeons addressed to Dr. E. Andrews, Professor of Surgery in Chicago Medical College.

As they contain much information respecting the drug, we lay the letters before our readers as a supplement to what has already appeared on the subject.

The first letter is from the Surgeon-in-Chief of the Army of Ecuador, Dr. Oblonoxato Auriboje, and is as follows :

Guayaquil, Jan. 12, 1872.

Senior Dr. Andrews :

Dear Sir,—I have the honour to answer your valuable letter of Nov. 15 last year. The reason why I did not do it by return steamer, was because I had been absent from Guayaquil for thirty days.

Concerning cundurango, I can assure you that it is a very efficacious remedy in the syphilitic affections of the mucous membrane ; in several diseases of the skin, especially the herpetic ; in several eczemas, and in most of the diseases which arise from impure blood.

In rheumatism it is a powerful recourse, especially in the fibrous and muscular forms, after first having suitably prepared the patient.

In cancerous diseases it is a powerful alternative—above all if the disease is not very old. Of cases of radical cure I only know two—one a cancer of the tongue, whose history you will see in the periodical "*El Nacional*," No. 100, and the other a case of cancer (not ulcerated) of the right breast—terminated successfully under the use of cundurango. Great improvements of ulcerated cancers are seen every day. To-day I have a case of an enormous cancer of the right breast. That the progress of the disease has stopped is indubitable. It is about eight months old. It seems as if the action of the medicine is more certain in young persons than in subjects of old age. In external diseases I make use of local applications of different preparations of cundurango. Internally I have used infusion, and experience has shown me that this is the best mode for use.

I shall have much honour in communicating in the future all relating to scientific works on cundurango.

Yours truly,

OBLONOXATO AURIBOJE, M.D.,
Surgeon-in-Chief of the Army.

From this epistle it appears that the distinguished writer values the remedy most for its anti-syphilitic power, but that he also has great confidence in its ability to cure some cases of cancer.

The second letter is from Dr. Camilo Casares, Professor of Surgery in the University of Quito. It will be seen that the Professor relied on his published documents, to be forwarded by the next steamer, to place me in possession of his observations. Unfortunately these have not yet arrived, so that I can only say, in general terms, that he appears to endorse the efficacy of cundurango. I have written again for the papers, and when they arrive will acquaint the readers of *The Examiner* with their contents. Here is the letter :

Quito, 27th of December, 1871.

Senior Dr. Edmund Andrews, Professor of Surgery,
Chicago Medical College :

Dear Sir,—I have the pleasure of answering your valuable letter, dated in Chicago on the 15th of November, 1871, assuring you that by the first steamer you will have all the data which I have been able to collect in the hospital which is in my charge, as well as in my private practice, in regard to the properties of cundurango. The many contradictory opinions which this plant has roused, has induced me to publish an article, if not scientific, at least with truth and sincerity, since so important a discovery can with difficulty be judged in the short time which this has had.

I am happy to avail myself of this opportunity to offer you my friendship.

Our communications, which no doubt from this time onward will be established, will be easy and secure by the favour of my much esteemed friend, Col. Rumsey Wing, American Minister in Ecuador.

I wish you had correspondence with Dr. Bliss, and you would deign to give him my respects. The rudeness and want of justice with which this gentleman has been treated in the

Times for his opinions in regard to cundurango, have vividly excited my sympathy for him.

From your friend and obedient servant.

CAMILO CASARES,
*Professor of Anatomy and Surgery in the
University of Quito, Ecuador.*
Fourth Street, No. 36, Quito.

The third letter is from Dr. Augustin Ruiz, of Loja. This town, Loja, is the capital of a province of the same name in the heart of the Andes, and is in the region where the cundurango grows, and where its qualities were first experimented on. It will be seen that Dr. Ruiz offered to sell me the article, delivered in New York, at two dollars a pound, when Bliss and Keene were doing it out at forty dollars a pound. It will also be noticed that the old Indian in Loja who first took it, and is reported by Dr. Bliss to have been thereby cured of cancer, is stated by Dr. Ruiz to have had nothing but tertiary syphilis ; and, further, that he is not aware that cundurango possesses any power to cure cancer. He is, however, like the other Medical gentlemen of Ecuador, strongly impressed with its anti-syphilitic power.

Loja, January 14, 1871.

Prof. Edmund Andrews :

Dear Sir,—I have received, on the 6th inst., your most valuable letter of November last year, wishing me to communicate to you my opinion of the efficacy of cundurango in the treatment of syphilis and cancer, together with some of the facts which have come under my own observation. In reply to this I shall state the following :

The cundurango was only known in this province as a poison, with which dogs were killed, until a woman—whose husband, *et. 50*, who was suffering with constitutional syphilis, from which almost his whole body, and especially his face, was ulcerated—wishing to get rid of him as she was unable to support him, resolved to kill him with the plant in question, and began to give him a decoction of it under the pretext that it was a remedy which she had been advised to use for him. The poor old man took his first portion, which his wife hoped would settle him. But seeing that her object was not accomplished, and attributing the bad result to a too small dose, she continued to administer it to him daily. But to her great surprise, at the end of eight days, her husband commenced to get better rapidly, and at the end of one month he was completely cured. The husband, on the other hand, was also surprised at having recovered from a disease which he had had two or three years, and with which he had expected to die, and he asked his wife what the so miraculous remedy was which had produced in him such a famous cure. She disclosed to him that it was cundurango which she had given him, and which had done him so much good. This, sir, is the origin of this discovery. Since then the town, which was overflowed with syphilis, has known this remedy, and it has never failed yet during a period of about forty years. I have used it for about six years in more than thirty cases of tertiary syphilis, and in none has it failed to produce a radical cure in less than forty days.

Chronic rheumatism, and some kinds of incipient paralysis dependent on the same, have been treated and cured by cundurango, and with good result. I have administered it in two cases of this disease, and in both obtained the most happy results.

As to its anti-cancerous action I can say nothing, as I have not tried it in this disease, no well confirmed case of this kind having ever presented itself to me. But let me tell you that this remedy acts as an alternative in all diseases of the skin, modifying and curing most of them. This is all what I, as a physician, have observed about cundurango.

The cundurango on which our observations have been made, is the one which grows in our province, Loja, although it is said to grow in other parts. As I, however, know only ours, I am unable to say whether the others possess the same Medical virtues. We have only administered it in decoction. Cort. cundurango, \mathfrak{ss} to aqua Oj, boiled down to \mathfrak{xij} . This decoction to be taken daily, divided into three draughts. After twelve days we have increased it to \mathfrak{ij} of the bark, to the same quantity of water.

If you need a few quintals (100 lbs.), I shall be able to afford about 50 quintals of the genuine bark, sent to Guayaquil or to New York, at the price in Guayaquil of 80 dols., and in the United States of 100 dols. If you need any, inform me when convenient to send.

Your most obedient servant,
AUGUSTIN RUIZ.

The last letter is from Dr. Jose Maria Eguiguren, brother of the Governor of the province of Loja. Dr. Eguiguren was the first physician to experiment on the article, and though he afterwards abandoned his practice to go into political life, his reports were the means of causing Prof. Casares and Surgeon-General Auriboje to take up the investigation. The doctor says that the Indians, from whom he first obtained the remedy, use with it another plant, which very powerfully increases its efficacy. Of this other plant he gives no description, and the specimens which he promised have not yet arrived.

Loja, February 3, 1872.

Senior Dr. Edmund Andrews:

Dear Sir,—When at the receipt of your favour of last year, I did not answer it immediately, it was because I wanted to give you an exact account of all the observations in regard to *cundurango* which I had made in my practice. Know that it is the terrible whip which the human species has against the syphilitic diseases; likewise against the cancerous affections, in certain cases of which all the resources of the art have proved so inefficient; also, in diseases of a rheumatic character; in various neuralgias, otalgias, cutaneous diseases, and in many of those which arise from impure blood. Although it has proved a specific in so great evils, it nevertheless gives excellent results in others—for instance, in dysentery of a putrid character. Unfortunately, a criminal fraud has given discredit to this so famous plant. There have been introduced into the market others of various families in excessive quantity, and of much inferior quality to that which has been made use of in our observations. Like the *cinchona*, it has been wished that all varieties should enjoy the same reputation. There are recognised in our regions five varieties of *cundurango*: 1st. The red, which, although very scarce, is superior in activity to all the others; 2nd. The yellow, which also is very scarce; and the three others, which only differ by their fruit, are found in great quantities. As we owe this discovery to the natives of our soil, these have also presented us with a powerful help in the efficacy of the mode of using this plant, uniting it with an extract drawn from a bark called *oriental*. I do not doubt that your attention will be called to the miraculous mode of operating of this other substance. It is not only commendable for its emetocathartic action, but it is a purgative worthy of all confidence, and it has an admirable effect in the various diseases of the liver, stomach, and intestines. Being an excellent purifier, when used in cases of impurity of the blood of a cancerous or syphilitic nature, it will lend an assistance so powerful that *he who administers so precious a vegetable, will never see his hopes fail*. Thus, also, when used in all the cases of diverse skin diseases, as these diseases seldom have any other origin than the disturbance of the different fluids of the human body. As a purifier, it frees the blood from all its impurities, and leaves a freshness to the skin, so that the patient has nothing more to wish. I should have much more to say if I should mention all which has come under my observation in my practice; but I wish you to form your own judgment over all that has been said, and give me the pleasure of receiving your letters.

I take this opportunity to offer you my friendship, and subscribe myself your most attentive and sincere servant,

JOSE MARIA EGUIGUREN.

P.S.—I forgot to tell you that by the next mail I shall send you a small package of the bark of which I have spoken to you, and afterwards I shall send you for trial a seed of the plant whose virtues I have heard so much about. I have been told that it is a very active poison.

Literature.

BRAITHWAITE'S RETROSPECT (a).

We do not often do more than announce the punctual appearance of Braithwaite, of which another volume is already in the hands of numerous subscribers. It seems to be as carefully selected as usual. Our own pages have as usual been laid under contribution, though we are sometimes scarcely prepared not to find other articles also

(a) "The Retrospect of Medicine," a half-yearly journal edited by W. Braithwaite, M.D., &c. London: Simpkin, Marshall, and Co. 1872.

extracted. It is doubtless the large amount of material at the disposal of the editors that brings this about.

We have more than once spoken of the characteristic feature of Braithwaite's—the Synopsis. In case any reader has not seen it, we this year give a specimen or two of this interesting part, selecting for the purpose affections of the nervous system.

ALCOHOLIC PARAPLEGIA.—Chronic alcoholism affects the whole nervous system, but the spinal cord is the part most prone to suffer. This is not uncommon in females. The condition of the patient is this:—She lies in bed or on a couch complaining of severe pains in all the limbs, more especially in the lower ones, which are much wasted, or of a sensation like electric shocks running through them; together with numbness and considerable anæsthesia, and at the same time only slight power of movement, or total inability to stand. There is generally enlargement of the liver, with sickness and all the usual signs of chronic alcoholism. The only treatment required is resolutely to break off the stimulants. There need be no fear of inducing delirium tremens, however much has been taken, and however suddenly it has been discontinued. (Dr. S. Wilks, p. 106.)

NERVOUS OR SICK-HEADACHE.—In those forms of sick-headache which are preceded by disturbed vision, or other signs recognisable by the patient as preceding an attack, the patient should lie down with the head as low as possible, and if the glimmering be on the right or left of the field of vision he should lie on the opposite side. He should at the same time take some powerful diffusible stimulant. By this means the defective supply of blood to some portion of brain, which is the real disease, is counteracted. There is always a loss of tone about the cerebro-spinal system in cases of this kind, and of course all measures calculated to improve the general health should be adopted. If the attack is followed or preceded by great mental depression nothing acts like half a drachm or a drachm of the ammoniated tincture of valerian. A remedy which is often given with great advantage during a severe attack is bromide of potassium in doses of 5, 10, or 30 grains, combined with 30 or 40 minims of *sal volatile*. If the attacks have been very frequent, or if there be any scrofulous tendency, the iodide of iron may be given in the following form:—R. Ferri et ammon cit., gr. v.; potassii iodidi, gr. ij.; aquæ, ʒj.; and, according to circumstances, 15 to 20 minims of tincture of henbane, or 20 to 30 minims of aromatic spirit of ammonia may be added. If the stomach is irritable this may be given in the effervescent form. In other cases citrate of iron with ammonia and strychnine may be given with great success. (Dr. P. W. Latham, p. 102.)

NEURALGIA.—Galvanism.—In order to cure neuralgia by galvanism we should use the continuous current, by means of small wet sponges attached to small conical conductors. The constant galvanic current has a truly marvellous effect over pain, whereas the interrupted current is of little or no service. The battery used should be Weiss's, sometimes known as Foveaux's. Eight cells of this splendid battery suffice, with very small sponges (about as large as would fill the end of a thimble). They should be applied to the painful part, an inch or two apart, and moved about, without being actually removed from the skin, for about two minutes. After resting a minute they should then be applied again for two minutes. Three very interesting cases illustrative of this plan of treatment are given. (Mr. J. Stead, p. 112.)

PERIVASCULAR SYSTEM OF THE BRAIN.—The vessels of the brain substance are themselves contained in a larger, rather loose, structureless membrane, completely surrounding the vessel. This membranous investment is easily detected with the naked eye in the fresh vessel; in some places a large space lying between them, in others the membrane lies so close to the vessel that it is with difficulty detected. Everywhere these membranous canals exist around the vessels, and they are quite sharply defined externally, as is proved by injecting them with wax. The use of these canals is probably to act as a reservoir for the fluid which exudes from the vessels, in order to permit of the rapid nutritive changes which must be necessary in such an organ as the brain. This perivascular system was first described by Robin in 1855. (Mr. W. W. Wagstaffe, p. 98.)

RESTORATION OF THE FUNCTIONS OF A NERVE AFTER EXCISION OF A PORTION.—The author reports a case in which he excised a small neuroma of the ulnar nerve, along with

half-an-inch of the nerve in its entire thickness, bringing the divided ends together with carbolised silk ligature, and closing the wound, which was treated on strictly antiseptic principles. The functions of the nerve had been in abeyance for nine years, and yet in fifteen days sensation had completely returned everywhere, except at the extreme tips of the two fingers. (Mr. T. B. Jessop, p. 110.)

THE DISEASES OF WOMEN (a).

THE fact that this work has reached its third edition within the short space of three and a half years is in itself a proof of its value, and the perusal of its pages fully confirms this impression. We look on it as being one of the most practical, and therefore, one of the most valuable of the works on obstetric medicine and surgery with which we are acquainted.

After two preliminary chapters devoted to the "Pathology and Etiology of Uterine Disease," the author proceeds, in a carefully-written chapter, to consider the "Diagnosis of Diseases of the Female Genital Organs," a matter often of the greatest difficulty, and the importance of which cannot be too strongly impressed on pupils, and not on pupils only, but also on practitioners, for unfortunately not a few of the latter are still in the habit of prescribing for patients presenting symptoms of uterine disease in the most empirical manner.

Passing over several chapters devoted to the consideration of the treatment of diseases of the external organs of generation, we come to a very valuable one, entitled, "General Considerations upon Uterine Pathology and Treatment." Dr. Thomas contends with much force and truth against the theories propounded by various authorities, that some one special cause is the primary element originating uterine disease, pointing out that neither inflammation of the parenchyma, hyperæsthesia of the uterine nerves, inflammation of uterine mucous membrane, nor sub-involution of the uterus can be looked upon separately as being the chief cause producing those troublesome affections from which women so frequently suffer, but that each and all play important parts in their production; and he lays down the following proposition—"that the pelvic organs of a woman who has hitherto been in perfect health may become gradually or suddenly diseased by one of the three following abnormal developments in the uterus—1st, disorder in innervation and circulation; 2nd, change in quantity of connective or muscular tissue; 3rd, change of position,"—assuming therefrom that "the first being the primary lesion the second and third may result from it," or that "the second being the primary lesion (as in sub-involution) the first and third may result from it," or that "the third showing itself in a perfectly healthy organ the first and second may be its consequences." The italics are our own, for while in the main assenting to the truth of the foregoing we feel bound to qualify our assent by stating that in our opinion no displacement or change in position of a perfectly healthy uterus ever takes place, except as the result of direct pressure exercised on it by some form of pelvic tumour or some analogous mechanical cause.

Alluding to the frequency of failure of the treatment in cases of uterine diseases, Dr. Thomas observes "that the most constant causes producing this unfortunate result are—

Imperfect diagnosis,
Erroneous prognosis,
Inefficient or inappropriate treatment,
Inattention to general management."

All four causes are of only too frequent occurrence; all traceable to the same neglect of a proper study of the pathology of uterine disease. We trust, however, that the day has really passed when practitioners will be

satisfied with treating symptoms, ignorant all the time as to what may be the diseased condition on which those symptoms depend.

But while all parts of the work under consideration are well worthy of careful perusal, the portions devoted to treatment are specially so. We are glad to find Dr. Thomas advocating the use of application directly to the interior of the uterus in cases of endo-metritis. We are satisfied that in many instances all other means will prove inefficacious. While at the same time we endorse the caution which Dr. Thomas gives as to the danger which may follow the use of intra-uterine injections, we ourselves never injected any fluid into the cavity of the uterus, except in cases of uncontrollable hæmorrhage, and even then only when the cervix is so patulous as to permit a rapid exit of the fluid. This latter precaution cannot be too strongly insisted on.

There is another method alluded to by Dr. Thomas for the treatment of corporal endo-metritis, namely, intra-uterine scarification, a mode of treatment which we have not ourselves practised, but which we think capable of effecting much good in a considerable proportion of cases. We have formed this opinion because we think the abstraction of blood from the inflamed or congested membrane to be a method likely to relieve the diseased condition, and also because our experience of the effects of local depletion by puncturing the cervix in cases of endocervicitis is very favourable.

We have noticed thus one or two of the leading features of Dr. Thomas's work; space prevents our following him into details. We commend the volume to all who desire to study the important class of diseases of which it treats, and we look on it as a most valuable addition to the works already in existence on obstetric medicine and surgery. Having thus expressed our opinion of the volume under review, we feel we can hardly be misunderstood by the author in also expressing our regret at his having frequently made use of terms which in this country at least are not generally understood, and which could easily have been dispensed with. Thus *hyperplasia* and *hypergenesis* are words unfamiliar to the general reader; and we hold that there cannot be a greater excellence in a writer than the use of simple words and the avoidance of new terms, when such is possible. Again, Dr. Thomas's sentences are sometimes so involved as to be positively obscure. Thus, speaking of predisposing causes of hyperplasia, he has the following:—"It should be borne in mind that nulliparity constitutes to a certain extent immunity, while utero-gestation abnormally completed, in consequence of puerperal inflammation or the depreciated assimilative functions of the woman, presents the most striking features in the etiology of the affection. I am very sure that in a certain number of cases the production and prolongation of hyperæmia in nulliparous women will be found to induce hypergenesis of connective tissue." It is to be regretted that so practical and valuable a work should be marred by the presence of such sentences as the preceding.

The volume is printed in a good clear type, and is copiously illustrated with woodcuts.

AN INVALID'S HOLIDAY IN IRELAND.

VISIONARY as the project may seem to be under the existing aspect of affairs, we still cherish the hope that the English *Malade Imaginaire* may be persuaded to make Lisdoonvarna and some other little known Irish watering places the object of a peregrination in search of health and the picturesque. Those who have looked into Whimper's "Scrambles," or observed the manners and customs of the normal continental tourist must be aware that dangers and inconveniences do not deter the valetudinarian from penetrating to obscure places which, when he gets there, he finds to be duller than Gravesend or Clontarf,

(a) "A Practical Treatise on the Diseases of Women." By T. Gallard Thomas, M.D., Professor of Obstetrics in the College of Physicians and Surgeons, New York. Third Edition. Pp. 784.

and we may not therefore be too sanguine in the expectation that the beauty and salubrity of Lisdoonvarna may sometime or other reach the ears of holiday makers who will not fear to make it the subject of their explorations and their literary ecstasies.

No sensible man can have any sympathy for the inane vanity which finds satisfaction in "having it to say" that it climbed one precipice of a bleak and uninteresting mountain higher than was achieved by some other rival for the admiration of the *gobemouches*. The inconceivable depth of that conceit is to be measured by the extent of the personal chronicles which it every year produces—by the swarming together in "Alpine clubs" of tourists each bent on blowing on his own horn a louder and more brassy blast than his neighbour, and by the unceasing yarn-spinning to which the British diner-out is subjected during the touring season. The professors of this art are seekers neither of health, pleasure, or beauty, they make their annual tour just to qualify themselves for the next winter's lionising, and to lay in a store of talk and boasting for the coming dinner season. To them no place is worth visiting except that which will ring as an achievement in the ears of listeners, and their patronage is neither to be hoped for or expected for the simple beauty or rugged grandeur of an Irish watering place.

But to those who travel for the lawful delights of travelling, Lisdoonvarna and the seaside places of Clare, as expounded by Dr. Mapother (*a*), cannot but prove attractive. The second edition of his pamphlet repeats the valuable information and persuasive argument which we noticed in the first, and if we could make sure that a copy would reach the hand of every intending tourist we might be satisfied that, at least, the seaside places of Clare would have abundant and appreciative visitors. The matter of Dr. Mapother's pamphlet—itinerary and Medical—is instructive and interesting, and the reader feels himself half way to the Clare watering places before he lays it down.

Medical News.

Royal College of Surgeons of England.—The annual election of Fellows into the council of this institution was held last week, without a contest, a circumstance which has not occurred for twelve years. On the present occasion the retiring councillors, Messrs. Henry Hancock, surgeon to the Charing-cross Hospital, and Thomas Blizard Curling, of the London Hospital, Vice-Presidents of the College, were re-elected, and Mr. Barnard Wight Holt, of the Westminster Hospital (an institution which has not been represented in the council since the decease of Mr. Guthrie in 1856), was elected in the vacancy occasioned by the decease of Mr. Samuel Solly. The numbers polled by the candidates were as follows:—Mr. Hancock, 41, including ten plumpers; Mr. Curling, 31, including one plumper; and Mr. Holt, 30, including six plumpers. In the evening the Fellows dined together at the Albion Tavern, Sir William Fergusson, Serjeant Surgeon to the Queen, in the chair, supported by the Directors-General of the Navy and Army Medical Departments, the Presidents and Masters of the Royal Colleges of Physicians and Surgeons and Society of Apothecaries, Bishop M'Dougal, Mr. D. Dalrymple, M.P., both Fellows of the College; Dr. Wiblin-Her Majesty's Quarantine Officer at Southampton; Messrs. Lund and Turner, of Manchester; Green, of Bristol; Jones, of Plymouth; Baker, Evans, Tait, and Thomas, of Birmingham; Lingan, of Hereford, &c., and an unusually large number of metropolitan Fellows.

University of London.—At an examination of candidate, for the degree of D.Sc., Alexander Muirhead, of University College, passed in Electricity; and Henry Newell Martin, M.B., of Christ's Cambr. and University, in Animal Physiology.

(a) "Lisdoonvarna Spas and the Seaside Places of Clare." By F. D. Mapother, M.D., Professor Royal College of Surgeons Dublin Fanning and Co. Pp. 50.

University of Dublin.—The following degrees were conferred on the 26th ult. :—*Doctor in Medicine.*—Francis Theobald Butler, Edward Jones Cooke, John Joseph Franny. *Licentiate in Medicine.*—Thomas Joseph Kelly.

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this request.

All communications intended for insertion, must bear the name and address of the writer; not necessarily for publication, but as a voucher of good faith.

Rejected MS. will always be returned, if a request be received from the author, within one week after the article or letter has been declined.

SUBSCRIPTIONS IN THE UNITED STATES.—A Correspondent has drawn our attention to the fact, that some of the houses in the United States are charging the enormous figure of 15 dollars per annum (more than £3) for supplying this Journal to different parts of the States. We beg, therefore, to state that we shall be happy to supply the same regularly post free per annum, if paid in advance, for considerably less than half this amount, viz., six and-a-half dollars (about £1 6s. 6d.), either direct from our offices in this country, or through our recognised agents in the United States.

TO OUR SUBSCRIBERS.—It having been suggested to us that it would be a matter of great convenience to Subscribers visiting the metropolis to know where they can give instructions for their letters to be addressed previous to leaving home, we have pleasure in informing them that the Publisher has consented to take charge of letters addressed to his care, and that he will place a desk at the disposal of Subscribers whose names are upon our lists, for short correspondence, where such accommodation is desired.

CONVERSAZIONE AT THE ROYAL COLLEGE OF PHYSICIANS, LONDON.—We are asked to correct an error which appeared in a contemporary last week. The charts illustrating the Geographical Distribution of Certain Diseases, were exhibited by Mr. Haviland, not Hairland, as reported.

THE ANTI-CONTAGIOUS DISEASES ACTS ASSOCIATION.—We are asked to state that Mr. P. A. Taylor, M.P., has written to the National Association for the Repeal of the Contagious Diseases Acts, requesting to be admitted to membership of their Association, and sending a donation of £50.

SURGEON HOGG, Woolwich.—The case is, as you remark, a curious one. It is, moreover, very interesting, and we have great pleasure in giving it space in our columns. If you will kindly forward the original notes to which you refer, they shall receive our earliest attention.

THE MEDICAL CLUB.

To the Editor of the "Medical Press and Circular."

SIR.—At the extraordinary general meeting held at the Club on the 30th May last, it was unanimously resolved "to continue the Club on the proprietary principle."

Captain Valpy (late of the 89th Regt.) having submitted a proposal to the meeting to become the future proprietor, negotiations have since been concluded with that gentleman, and on the 1st inst. he undertook the responsibilities and liabilities of proprietor of the Medical Club.

Captain Valpy's experience in the Commissariat and Paymasters' Department of the Army for over nineteen years, and his having been a member of the Club for several years, will afford him very great facilities for further developing and improving the management of it. Captain Valpy proposes to continue the Club as a "Medical Club," and to place it upon a new and enlarged basis. A copy of the details, of which, when completed, will be forwarded to each member.

Your obedient servant,

LORY MARSH,
Late Hon. Sec. and Treasurer.

July 3, 1872.

MAD LITERATURE.—We have received the first number of a very curious little periodical, entitled "Loose Leaves." In an opening article the Editor of the paper and Proprietor of the Asylum—in which we have reason to believe the articles are chiefly written and even set in type by the inmates—Mr. Hyslop explains the object of the publication as follows:—"It is, I believe, the first magazine of the kind ever published in England. Let us hope it will be but the beginning of a fruitful crop of what may be termed 'mad literature' in the restricted sense of the term. The non-restraint system, in connection with the treatment of the insane, is now universally practised throughout the country; and many 'mad doctors' and superintendents of asylums, private and public, are constantly devising means for the healthful recreation of the unfortunate inmates. To out-door recreations and indoor amusements I would earnestly recommend them to add a 'little dabbling in literature.' It is not necessary that the mind should be overstrained, or that excessive labour should be taken in the adornment of the various contributions." The idea is certainly a good one, and we must candidly confess that among the contributions is to be found some really sound common sense; original ideas abound in elegant language, and writing to which even some of our literary journals would probably not refuse space. Further than this, "Loose Leaves" is excellently turned out, and reflects great credit upon Mr. Hyslop, whose well ordered asylum at Church Stretton, in Shropshire, we had occasion to refer to in an article some time since. To those who feel an interest in this class of literature, especially a novelty of this kind, will be glad to know that they can obtain a copy of the Publishers, Baillière, Tindall, and Cox, by forwarding two postage stamps.

DIGESTIBLE COD-LIVER OIL.—Mr. Fox, of Manchester, the introducer of "Palatable Cod-Liver" and "Castor Oils" has, we understand, registered a new title, "Digestible Cod-Liver Oil," especially for hospital use. The oil is exactly the same as that sold as "Palatable Cod-Liver Oil," the only difference being in the absence of the expensive syrups, which enables the Proprietor to sell the pure oil at a very cheap rate to large consumers.

Irish Poor-Law Intelligence;

UNDER AUTHORITY OF THE

IRISH MEDICAL ASSOCIATION.

MONAGHAN UNION.

THE LATE DR. TEMPLE.

THE Board placed on their minutes the following resolution:—"The Board of Guardians assembled this day have to record their regret at the death of William Temple, Esq., who has been Medical officer of the house since its first opening, now thirty years ago, and who discharged the duties of his office to the entire satisfaction of the Board."

The Chairman said that Dr. Temple, as Medical officer of the Workhouse, discharged his duties with great humanity and, at the same time, with perfect economy. He did not squander the rates at all. He acted with judgment and discretion. At the same time nothing could exceed the health of the inmates of the house. No number of children in any other rank of life assembled together had on an average the same good health, while there was a smaller average of deaths. The Poor-law Inspectors had always borne testimony to the fact.

MONAGHAN DISPENSARY DISTRICT.

The Clerk read a letter from the Poor-law Commissioners, dated June 25, expressing their sanction of the remuneration proposed to be allowed to Dr. Irwin for his services as temporary Medical officer of the Monaghan Dispensary District—namely, at the rate of £15 a month.

THE MEDICAL OFFICER.

The next business was as to the appointment of a Medical officer, and the salary he should receive.

The Clerk mentioned that the salary of the Medical officer had been £80 a year since the 10th of January, 1849, the time the fever hospital attached to the workhouse was opened. The late Dr. Temple was appointed Medical officer of the workhouse on the 15th of December, 1841, at a salary of £40 a year, which, on the 24th of March, 1847, was increased to £50. He was appointed to the temporary fever hospital, which then adjoined the workhouse, on the 18th of October, 1848, at a salary of £25 a year. This temporary hospital was abolished in January, 1849, when the present fever hospital was opened, and the salary was then fixed at £80 a year for the workhouse and fever hospital.

Mr. M'Nally—I object. At the opening of the house the salary of the Medical officer was £40 a year, and I consider, taking everything into account, that £50 is a sufficient salary at present. The salaries of the clergymen, the salary of the master, and the salary of the schoolmaster are the same as at first. For these and other reasons I propose that the salary of the Medical officer be £50 a year.

Mr. Richardson—Are you aware that there was no fever hospital attached to the house when the salary was £50?

Mr. Watson—I propose that the salary of the Medical officer be continued at £80 a year, the same that Dr. Temple received, no matter who may be appointed.

Mr. M'Nally—I propose, as an amendment, that the salary be £50 a year.

The proposition was not seconded, so that the salary was continued at £80 a year.

LISNASKEA UNION.

SALARIES.

At a late meeting of the Lisnaskea Board of Guardians the salary of the Medical officer, Dr. Sandels, has also been increased, from £35 to £45.

An inquiry has just been held by Mr. Hamilton, Poor-law Inspector, into the conduct of Dr. Holtan, Medical officer of Maguiresbridge Dispensary District, in a late case, where a child, ill with fever, was alleged not to have met with proper attention and care. The child died on the sixth day of illness, and received only one visit during that time. The decision of the Poor-law Commissioners on the report of the Inspector will be made in a short time.

CARLOW UNION.

The following letter was read by the Clerk:—

Bagenalstown, 26th June, 1872.

GENTLEMEN,—Bridget Murphy, an aged, infirm, worn-out nurse-tender in this town, is at present a Dispensary patient. She is too ill for removal to the Union, and at the request of the relieving officer I certified to that effect. I am supplying her with such drugs as I consider suitable, but the *real medicine* in her case (and that calculated to restore her to her usual health with true economy to the ratepayers) is nutritious food, and this she has no means of procuring. The relieving officer, I believe, is giving her what he considers requisite, but I deny his competency to judge of the requirements of this case. Your "order" of the 28th May, "requires" me to discontinue the practice of securing (by an order of the relieving officer) the supplies of food, &c., I, the Medical man responsible for her treatment with humanity tempered by due economy, deem essential to her welfare, and you supply me with a copy of the strictures of the Auditor on that practice, in which I find this remarkable statement, "That the power of giving provisional relief under the 7th sec. of 10 Vic., cap. 31, is restricted to the Relieving Officer, and the Medical Officers of Dispensary Districts are in no way authorised to direct his action." This, with your order to accept this as law, takes quite out of my hands the most vital element in the treatment of Bridget Murphy, and I now appeal to you to obtain for me the freedom of action necessary for the humane and proper conduct of such cases.

To me it seems that this interference with my authority over the dietary of my Dispensary patients is about as reasonable as if a law were passed forbidding me to prescribe for a private patient, and directing me instead to write a certificate to the apothecary, saying, "Mr. A. B. has got typhus fever. Send him what drugs, and in what doses, you think he requires."—I am, gentlemen, your obedient servant,

JAMES J. TRAYER, M.B., Medical Officer.

The Board of Guardians, Carlow Union.

TABLE showing for EIGHT LARGE TOWNS, &c., the AREA, in Statute Acres; the POPULATION in 1871; the ANNUAL RATE OF MORTALITY per 1,000 Inhabitants represented by the Number of Deaths registered during the Week ending Saturday, 29th June, 1872; the Total Number of BIRTHS AND DEATHS registered during the Week, with the Number of DEATHS at certain Ages, and from SEVERAL CAUSES; &c.

ABSTRACT OF THE ANNUAL REPORT OF THE POOR-LAW COMMISSIONERS.

Poor-law Commission Office, Dublin, 30th March, 1872.

THE Commissioners submit in the first place a summary of weekly returns of persons relieved in the workhouse and out of the workhouse for fifty-two weeks.

IN AND OUT-DOOR RELIEF.—The following figures represent the average daily numbers shown in each diagram for the whole series of seven years:—1865-66, 52,121 in, 10,040 out; 1866-67, 50,241 in, 12,205 out; 1867-68, 53,017 in, 14,940 out; 1868-69, 53,757 in, 16,862 out; 1869-70, 50,964 in, 18,296 out; 1870-71, 47,910 in, 21,474 out; 1871-2, 45,333 in, 22,552 out.

These statistics show a further decrease in the number of inmates of workhouses which on February, 1872, was less by 1,211 than the number at 1871, and less by 5,438 than in 1870. The difference between the present and preceding years has in the latter portion of the series of weeks been declining in consequence of the epidemic of small-pox.

The number of persons receiving out-door relief has further increased from 25,363 to 28,490 in the fifty-two weeks. We have before entered into the considerations which oblige us to disregard any ordinary increase or decrease of the number of inmates of workhouses.

The number of children out at nurse has increased from 1,428 to 1,540.

The increase of out-door relief from 23,544 last year to 27,010 is thus distributed—the permanently infirm class, 1,485; the widows, 518; and the temporarily disabled by sickness or accident 1,463; the increase of the widow class being only one-third of the increase of each of the other two classes.

MORTALITY IN WORKHOUSES.

The total deaths in the workhouses has been 10,563, which, compared with last year's numbers, shows a decrease of 56 deaths and a decrease of 385, compared with the preceding year.

DEATHS FROM SMALL-POX

No less than 462 deaths from small-pox have taken place in the workhouse hospitals of Ireland in 1871-2 in

comparison with only one single case for 1869-70, and with no more than 13 in 1870-71.

The whole number of deaths by small-pox registered in Ireland in the year 1871 is now known to be 647, in comparison with 92 in 1870.

SMALL-POX QUARANTINE.

In the appendix is found correspondence regarding a proposal of the town council of Cork to establish a small-pox quarantine.

In this correspondence it was shown that the system of quarantine adopted in 1871 to prevent the importation of cholera was not applicable to an epidemic of small pox existing in Great Britain for the purpose of preventing its extension to Ireland.

It needs very little reflection to see that a disease which, like small-pox, lies dormant in the system from twelve to sixteen days after the contagion has been caught could not be prevented by any means whatever in the nature of quarantine from crossing the channel into Ireland, where a continuous stream of passenger traffic is going on daily and nightly at several points of the coast in a passage of only a few hours' duration. With equal reason, and with equal chance of success, quarantine might be established between one town and another in the same island.

The parochial authorities in Scotland continue to remove dangerous lunatics hand-cuffed from Scotch lunatic asylums to Irish workhouses. Recent instances of this practice are given in the appendix; and we may here observe that they are regarded in Ireland with feelings of great dissatisfaction.

INCREASED COST OF IN-MAINTENANCE.

We now proceed to the statistics for the year ended 31st September, 1871.

An increase of expenditure has taken place under the head of In-maintenance, amounting to £682, notwithstanding that a considerable decrease, amounting to 4,919, has taken place in the total numbers receiving relief, and that the average daily number in the workhouse had decreased to the extent of 3,181. The increased expenditure arises from the considerable increase which has taken place in the cost of provisions, such increase being about 2d. per head per week for each person relieved. An increase of £4,357 has taken place under the head of Salaries and Rations of Officers, a portion of which increase is also accounted for by the increased price of provisions. But the most marked increase is that under the head of Out-door Relief, namely, £10,563, arising from the continuous income in the numbers to whom such relief is extended. A slight decrease has taken place in the total number admitted in sickness during the year. A considerable increase, however, has taken place under the head of Fever and other dangerous contagious diseases.

The following is a statement of the Parliamentary Grant:—

	Amount claimed and granted for the Year.		
	£	s.	d.
Medical purposes ...	64,280	17	0
Educational purposes ...	7,563	15	7
Total ...	71,844	12	7

GROSS RATING AND EXPENDITURE.

The total disbursement of poor-rates for all purposes, viz., relief, medical relief, burial grounds, registration of births, deaths, and marriages, and sanitary measures was in 1870 £815,973, and the amount of poor-rate collected £753,345, the expenditure making a poundage of 1s. 2½d. in the pound on the valuation. In 1871 the expenditure was £840,135, or 1s. 3½d. in the pound, and the poor-rate collected only £739,053, the difference between the expenditure and collection being to a great extent covered by the Parliamentary grant.

DISSOLUTION OF MILL STREET BOARD OF GUARDIANS.

It has fallen to our lot in the course of the past year to be obliged to exercise once more the power of dissolv-

ing the board of guardians of a union. This power, which during the famine period was exercised in no less than forty-three cases, had not been used for more than twenty years, and the occasion for using it once more arose in the Millstreet Union, which is situate in the county of Cork. The board, consisting of fourteen ex-officio and the same number of elected guardians, absolutely ceased to meet, the legal quorum of three having failed to be obtained no less than nine times in the course of twelve weeks, and after a long series of remonstrances addressed both to the Board collectively and to its members individually, it appeared with sufficient distinctness that, with one solitary exception, no member of the Board would willingly attend the weekly meetings. This person, an elected Guardian for one of the electoral divisions, had been from the time of his election a constant attendant at the weekly meetings, and so exercised his functions that after a certain lapse of time he and the Clerk of the Union had the board-room week after week entirely to themselves. We shall not enter into the particulars of that course of conduct of the elected Guardian which produced such a strange result, nor are we perhaps wholly acquainted with them, but we must say that the other members of the Board who abandoned the performance of their duty for a reason like this, did not act in a proper spirit, or acquit themselves creditably as guardians of the poor. The Vice-Guardians were warmly welcomed by the ratepayers, especially by those resident in Millstreet, at whose request they at once took in hand a project for providing both the workhouse and the town of Millstreet with a permanent supply of pure and wholesome water. We have entered into particulars about the water supply, because they are suggestive of one of the modes of action by which the superintending authority in the administration of the Public Health Acts may be enabled to accomplish effectually the execution of necessary works.

PROCEEDINGS UNDER THE MEDICAL CHARITIES ACT (IRELAND).

We now submit the report of our proceedings under the above-mentioned Acts of Parliament. In a subjoined table is given a summary of the relief afforded under the Medical Charities Act for the year.

The comparison of the numbers for the two last years in this table shows, for the first time since the enactment of the Medical Charities Act in 1851, a diminution in the number of patients of both classes, both of those attended at their own homes and of those attended at the Dispensary stations, in all the provinces of Ireland. Of Dispensary cases, for the last compared with the previous year, there has been a decrease in Ulster of 8,192 cases, in Munster, of 6,686, in Leinster, of 12,451, and in Connaught of 6,404. Of domiciliary cases there has been a decrease for the latter year of 4,913 cases in Ulster, of 2,145 in Munster, of 762 in Leinster, and of 1,596 in Connaught;—giving for the whole of Ireland a decrease of 83,733 Dispensary cases and of 9,416 of those attended at the patients' homes.

The next table gives the expenditure on medical relief under the Medical Charities Act, including the expense incurred in carrying out the Vaccination Acts.

The figures for the two last years in this table show an increase of total expenditure for 1871 compared with 1870 of £5,069, nearly half of which, viz., £2,336, has been occasioned by the existing epidemic of small-pox, the panic caused by which has created an increase of applications for vaccination, and among the adult population a quite exceptional number of applications for re-vaccination, whereby the vaccination fees of the Dispensary Medical Officers have been increased from £6,334 for 1870 to £8,720 for 1871. A large proportion of the increased expenditure has fallen on Leinster, viz., £3,021. In Munster the increase has been £1,176, in Ulster £417, and in Connaught £455. The disproportionate increase of expenditure is also mainly attributable to the epide-

mic, which has hitherto more especially prevailed in this province.

The next table sets forth a comparative statement for the two years ended September 29th of the items of the general expenditure under the usual heads.

	1870.	1871.
1. Medicines and medical appliances	£23,707	£23,420
2. Rent of Dispensary buildings	7,353	7,363
3. Books, forms, stationery, printing, and advertising...	2,694	1,166
4. Salaries of { Medical Officers	77,915	80,725
{ Apothecaries ...	2,362	2,503
5. Fuel, porters, and incidental penses	10,763	10,001
Expenses under Vaccination Act :		
6. Vaccination fees and other expenses :—		
Fees to Medical Officers	6,384	8,720
Other expenses	7,140	907
	£129,936	£135,003

Under the first head there appears a decrease of expenditure on Medicines and Medical appliances of £287. This decrease is in accordance with the above-mentioned diminution in the number of applicants for Dispensary relief in 1871. The usual increase under Salaries of Medical Officers, which has occurred every year since the establishment of the present system of Dispensary relief, amounts for 1871 compared with 1870 to £2,949, and is rather greater than the corresponding increase for 1870, which was £2,558.

The average poundage on the Poor-law Valuation of Ireland to provide for the above-mentioned total expenditure was 2'44d., which is slightly higher than that for the year before, viz., 2'36d.

In the course of the year, skilled midwives to attend on midwifery cases so long as the course of the labour is natural, were appointed in ten additional dispensary districts. Although these most useful appointments, of which there are now 178, increase from year to year, we think it is much to be regretted that they are not generally adopted by the dispensary committees.

Since the date of the last Annual Report, fifteen Dispensary Medical officers have been superannuated under the Poor-law Medical Officers Superannuation Act. With few exceptions, the Guardians have awarded in all such cases two-thirds of the salaries as retiring allowance, the highest award permitted by the Act.

The next table exhibits the progress of vaccination by the Dispensary Medical officers under the Compulsory Vaccination Act for the last seven years, and shows the continuous decline yearly, except for the last year, in the number of persons vaccinated who were exempt from the operation of that Act. The table shows only a further increase of vaccinations of children subject to compulsory vaccination of 3,996, but, instead of the steady decrease year by year of the numbers vaccinated among those exempt from compulsory vaccination that has taken place since 1863, there has been the extraordinary increase of 35,673 cases. The explanation of this quite exceptional demand for the vaccination of children above seven years of age, and of adults, and for the re-vaccination of adults, which has contributed considerably to the increase in question, is to be found in the panic caused by the present small-pox epidemic. Accordingly, it is remarkable that more than half of the increase—viz., 18,741 cases—have occurred in Leinster, in which hitherto the disease has been more alarmingly prevalent than in the other provinces. The ascertained fact to which we have drawn attention formerly, that three-fourths of the entire mortality caused by small-pox falls upon children under five years old, makes manifest the great importance of early vaccination; and with the view to procure information on this important point, we requested the Dispensary Medical Officers, in making their vaccination returns for last year,

to state the numbers of children vaccinated by them who were under one year old. We have accordingly learned that in 1871, of 44,897 children under eight years old vaccinated in Ulster, 37,663 were under one year old; in Munster, of 37,798 of the children under eight years, 30,018 were under one year old; in Leinster, of 31,943 of the former class, 24,486 were under one year; and in Connaught, of 24,415 children vaccinated under eight years, 17,246 were in their first year;—giving for all Ireland 109,418 infants vaccinated in their first year, out of the 139,053 vaccinated under eight years old.

It is gratifying to find that the numbers of children under eight years old vaccinated during the last exceed those for the year before in each province, giving a total increase for the whole country of 4,000 cases. There is good reason to believe that the increase in cases of this class is to be explained by the fact that we are approaching a complete vaccination of the children born within the year. The number of children whose births were registered by the Registrar-General for the year ended September 30th, 1871, was 151,159, and the vaccinations under the Compulsory Vaccination Act for the same year were 139,053. It is true that of this number many must have been children between one and eight years of age whose parents had neglected to have them vaccinated in their first year; but it is also to be borne in mind that a large number of the 151,159 children would have died in their first year, or would have been vaccinated by private practitioners.

The numbers of cases of fever, scarlatina, and small-pox attended by the Dispensary Medical Officers for 1871 show an inconsiderable decrease.

In dispensary practice, cases of small-pox would often occur in which the patients or their friends resisted all inducements to avail themselves of resort to the hospital, and on these occasions it fell to the duty of the Medical Officer to cause every precaution to be taken which could be taken against the spread of that disease, by isolating the case as far as practicable, by the free use of disinfecting processes, and, finally, by taking advantage of the popular alarm to vaccinate or revaccinate the residents.

These precautions have been attended by success in the greater part of Ireland, for there are very few unions in which the disease has become epidemic, although a considerable number have been visited by sporadic cases. The returns of deaths in the workhouses show 126 unions without any death by small-pox, sixteen unions with only one death, and twelve not exceeding six.

Under ordinary circumstances the treatment of contagious disease in Dublin is not undertaken by the Poor-Law authorities, but the latter are able to obtain admission to hospitals not under their own control for all contagious cases arising within the scope of their jurisdiction.

In neither union was that important adjunct to a contagious hospital, a convalescent department, unprovided for; so that from the commencement the patients have remained under Medical authority until they could return to their homes without danger of giving contagion to their families or neighbours.

Correspondence shows beyond question the dangerous character of hospitals for contagious disease which are not provided with convalescent accommodation.

Regarded in its character as a protection from the spread of contagion, the convalescent ward should, for all practical purposes, be in connection with the hospital itself; for thus only can the patients discharged from the wards for treatment be kept effectually under Medical authority—detained, in fact, until pronounced safe.

The share of the burthen of the Dublin epidemic borne by the two Dublin workhouse hospitals will be seen from the following figures. The total number treated in nine hospitals to the 23rd March was 2,541; of which number 1,152 were treated in the workhouse hospitals and 1,389 in the other seven hospitals. For such of the patients as are sent into the latter hospitals by Poor-Law officers, the guardians pay the cost of treatment and maintenance.

THE ARMY SURGEON, HIS WORK AND WORKS (a).

By C. A. GORDON, M.D.; C.B., Dep. Insp.-Gen. of Army Hospitals.

(Continued from page 23.)

From the time, and even before, a young man joins the ranks of the army until the moment he quits them he is looked after and watched over, alike in health, in sickness, or when wounded, by the surgeon. It is the surgeon who tests his physical fitness for the arduous duties of military life when, as a recruit, he comes before him, picking him, as it were, from the less sound of his fellows. During the irksome ordeal of training the surgeon sees him from time to time, coming, when necessary, between him and the young man's instructors. When capable of taking his position among the effectives he is still watched over by his surgeon, who sees that his accommodation, his clothing, his food, are not only sufficient, but suitable, and that the recurrence of night duties, on guard and otherwise, is not such as to impair health. When ordered on foreign service, the ship in which he embarks has been carefully examined by the surgeon, who has satisfied himself, in respect to space, ventilation, water, and food, that everything has been done for his comfort. During the voyage the surgeon is present watching over him, and obliged by regulations to personally examine every soldier once a day, as also to see that all conditions calculated to preserve health are rigidly fulfilled. On reaching his destination, in whatever country or condition, the surgeon is present with him; and it is under such circumstances that the great responsibility of the Medical man takes place, for now, whether it be service against an enemy or exposure

to the more subtle and deadly spell of epidemic influence, the surgeon not only runs the same risks of exposure as do those of whom he has charge, but has, in addition, when fatigued and often exhausted, to exert himself while they rest, and minister to the pressing needs of his stricken patients. Now, also, comes the real struggle between professional knowledge and death. Take, for example, such diseases as heat-apoplexy and cholera in India. Decision on the part of the Medical officer at the first onslaught, and they are readily combated. Pusillanimity and indecision for but a few minutes and the affections bid defiance to any after skill.

In battle a bullet drills its way through a limb, perhaps severs an artery, perhaps splinters a bone. The soldier drops confounded and panic-stricken. Still the surgeon is beside him, to stem the flowing life-stream it may be, to bind up the shattered member and see him sent to a place of safety, there to bestow upon him further care after the combat is over. And, may I ask, have you ever seen a stalwart soldier, in the wild excitement of battle, fall like a clod to earth as I have related? If so, you doubtless appreciate my picture. If, as is more likely, your lot has led you to more peaceful spheres, your memory will probably recall the fear and anguish with which a woman in the throes of childbirth clings to her Medical attendant. In no other conditions than those of the battle-field have I seen the counterpart, and yet men who know no better would fain believe that the surgeon is not needed while the fight rages. Not on the field of battle indeed! Who so instantly and loudly called for by the wounded man, soldier or officer, as the surgeon? What would be the effect upon those engaged, let me ask, were they without the knowledge that immediate aid was available? They would become demoralised were they but to suspect that, once struck down, they should be left for an indefinite time untended and bleeding on the field. And it is our proud boast that never in this respect do we shirk our duty. That such is the case is demonstrated by the number of those among us who have earned the proud distinction of the Victoria Cross for valour in the field; a number at least equal in proportion to that among our combatant brother officers. It is not indeed by one set of

(a) Presidential Address delivered at the St. Andrew's Graduates' Association, on Saturday, July 6th, 1872.

men, or by one class of arrangements, that battles are won, but rather by the harmonious and efficient working of all pieces of the mighty military machine. As each in its own sphere conduces to the general result, so let it in all justice have its due meed of merit; and certainly that branch of which I am myself a *pinion* is by no means the least important.

Then comes the terrible and anxious work of war hospitals. These establishments are selected, arranged, and provided with *personnel* and *materiel* under the orders and superintendence of the senior Medical officer, their position being determined with reference to the nature of the service on which the army is engaged, and the position of the force with reference to its base of operations. Often, also, suitable means of transport for the wounded have to be procured or improvised, and who so fitted as the surgeon to make the selection with reference to the nature of injuries, the description of roads over which the wounded have to be transported, and distance to which they have to be conveyed? Intermediate posts have to be selected *en route*, means being provided at each for supplying the wounded with temporary accommodation, assistance, and food; or, as now practicable, railway trains can be fitted up, the duty of selecting suitable cases for removal, and providing professional attendance, rests with the Medical department. Other duties, no less important, occupy the attention of the Medical department on active service. Individual sick and wounded have to be treated; such means as are practicable devised for protecting the health and consequent military efficiency of the troops; the General in command kept informed as far as possible of the number of those in hospital whose restoration to health may be anticipated after a certain time, of those who are permanently unfit, and, with reference to climate and other conditions of the country or district where hostilities are being carried on, the casualties that may be expected to arise by sickness, to enable the commander to estimate the numerical strength of reinforcements required to fill up the inevitable losses.

Much is said in military circles on the vexed division of the military services into combatant and non-combatant. In one sense, and that a very important one, who so entitled to rank among the former as the Medical officer, whose whole career is passed in combating enemies of humanity, whether they be physical and open as the "arrow," the shot, the shell in the day of battle, or hidden and mysterious as the epidemic, the exhausting sickness, the pestilence that walketh in darkness? No wonder, indeed, that such enemies thin our ranks and maim the survivors, in health if not in limb; accordingly, statistics of campaigns show that death is then busiest among the Medical officers, among whom a larger proportion perish than among their regimental brethren, and including the casualties of battle.

Let the fact, moreover, be borne in mind, that on foreign service not only have soldiers individually and in the mass to be attended, as I have endeavoured to indicate, but so have their wives and their children. Officers and their families are no less dependent upon their regimental surgeons. They can no longer take train to this great city to consult an eminent or fashionable man of the day, nor, indeed, would such affections as those from which they suffer, more especially in the more unhealthy regions of the tropics, give them time to do so. Thus, in their persons lives and interests of the highest national importance are for the time being in the hands of the army surgeon; and, may I add, the responsibility of the charge is, sometimes, at least, unequalled by the recognition awarded to it.

One more remark on the duties of the army surgeon. We shall suppose him and the troops under his charge returned to the United Kingdom, both, as is often the case, individually less active and robust than when they left it. Soldiers unable longer to perform military duty must be weeded from the ranks to maintain their battalions fit for the eventualities of military life. Some have

ailments, which, although as yet slight or obscure, will ere long unfit them, not only for the army, but incapacitate them from earning a livelihood in civil life; others, although suffering, it may be, from active disease, the result of climate or service, may be expected after a certain time to recover; while a third class, although unable to perform the duties of a soldier, are capable of labouring for their own maintenance. It becomes the duty of the Medical officer to discriminate between all these, and, having done so, to prepare his report in regard to each individual, so as to guide the commissioners charged with the bestowal of pensions to adjudicate in such a way, that, while bestowing upon persons what their special services and circumstances entitle them to, the interests of the British tax-payer shall be at the same time considered.

Here I may observe that in the performance of this duty of weeding the army of inefficient men, the army surgeon sometimes undeservedly finds himself the subject of remarks the reverse of flattering. Thus there are many men, who, although unfit for the duties of a soldier, are quite able to earn their living partially or entirely in civil life; accordingly, it is by no means rare to meet with old soldiers, hale and hearty, some of whom, it may be, had undergone a surgical operation, or been treated for a certain time in a civil hospital, and then discharged completely cured, notwithstanding that "the regimental surgeon could make nothing of him," for such is the ordinary comment. The explanation is easy. We must study the general efficiency of the whole machine. To ensure this, it is often necessary simply to replace a permanently injured fragment of the apparatus by a perfectly new, rather than patch and tinker that which never more could work satisfactorily in itself, or smoothly with those other cogs and wheels of immediate and co-ordinate action. So, also, if there is little or no prospect of a soldier being restored to military efficiency by protracted hospital treatment, the general interests of the service are adverse to his being retained upon the rolls of his regiment. Many men there are, also, who, whether their alleged incapacity be real or assumed, are alike unsuited to the army, and simply because, if they insist upon it, they will not perform their duties satisfactorily; they tell the surgeon they are stiff and rheumatic, that their former activity is gone, and the surgeon very properly takes their word for it. Such men, not of the very highest standard of truthfulness or morality, are not unfrequent visitors of civil hospitals. They soon learn to relate to surgeon and students sensational accounts of imaginary adventures. The army doctor, like his brother in civil life, is often a ready scape-goat, and as with the one so with the other, very undeservedly so.

The history of wars furnishes several illustrations of the influence for good or bad, in respect to the general interests of an army, exercised by the Medical department. That of Italy, in 1859, gave examples of insufficiency of surgeons as regards number, and inadequacy as regards professional capability, the results being, on the one hand protracted exposure of the wounded without assistance, and on the other attention which, when rendered, was scarcely less dangerous and injurious than its total absence. During the civil struggle in America, if we are to believe the author of "Battle-Fields of the South," the losses of life among the wounded through insufficient and improper surgical help, is given a place among the causes which led to the collapse of that army. If we look at the late great war upon the Continent, also, we meet with records of evils arising from insufficient surgical arrangements in *personnel* as in *materiel*. Thus we learn from accounts by correspondents and others on the spot that, notwithstanding all that was done by the Governments and by Societies, the wounded could not in all instances obtain sufficient nurses. After Sedan this was especially felt; nor were the wounded able to obtain, while in transit, those articles of nourishment of which they stood so much in need.

After the battle of Gorse, with five thousand four hundred wounded, M. Langenbeck had only four Medical

officers to attend upon them during the two days that elapsed before the arrival of the Sanitats detachment. After the battle of Gravelotte, a quarter of the wounded on the French side is said to have died; this catastrophe being attributable to defective means of transport, and to the want of first dressings. Many are said on this occasion to have passed two days and nights on the field, and, after that ordeal, to have been transported to Pont à Mousson, where for the first time they found assistance in the temporary hospitals established there. Again, the state of Lagny during December is said to have been beyond description. A thousand and upwards of wounded poured in day after day, their wounds needing to be dressed, themselves to be fed; no hospital in the place, but sheds, railway vans, the station, church, and mairie, all, for the time being, occupied as such (a).

If we retrace our steps to bygone times, we find it recorded, that so long ago as 1742 the efficiency of the Duke of Cumberland's army in the Low Countries was directly due to the talent and success with which Sir John Pringle applied hygienic measures to prevent and mitigate typhus and other diseases, the result of crowding, dirt, and bad food. According to the history of the Peninsular War, the Duke of Wellington, before making his successful attack upon Badajos, confided his plans to Sir James McGrigor, his principal Medical officer, and to him alone. The latter was able to send the sick, wounded, and impedita to Elvas in the rear, where suitable provision was made for them. The army was thus rendered light and active, and with it the great Commander struck his blow. So it was at Vittoria. The Duke had rapidly to attack the French. He "took stock" of his available force, and found it far inferior to that of the enemy. He consulted his chief surgeon, one of whose qualities was, that he kept count of the probable numbers who might be calculated upon to return to the ranks. This time the knowledge was acted upon. From various hospitals between five and six thousand men able to bear arms were pressed onward, and with his army thus reinforced the most signal victory of the Peninsular War was gained.

(To be continued.)

CHOREA IMMEDIATELY AFTER MARRIAGE.

By FRANCIS R. HOGG, M.D. ST. AND., M.R.C.S.E., ETC.,
Royal Horse Artillery, Woolwich.
Fellow of the Obstetrical Society, &c., &c.

CHOREA has been defined as an irregular tremulous action of voluntary muscles, especially of the face and limbs, mostly attacking young girls between the ages of six and fifteen, associated with dentition, intestinal irritation, worms, rapid growth, puberty, disordered menstruation, fright, poverty, or debility: with whooping-cough, scarlet or rheumatic fever:—may be hereditary or traced to an epileptic tendency depending on spinal curvature. Damp weather and unhealthy malarious localities predisposing; relapses are common. Peri or endo-carditis may supervene. The disease may suddenly and rapidly prove fatal, or run on from six days to seven months, the average period being about nine weeks, and in twenty-three years 1,355 deaths occurred in England. Dr. Barnes directs attention to chorea in pregnancy, and narrates thirty-nine cases which recovered, and seventeen proving fatal. The ages ranged from seventeen to thirty-five. The treatment consisted either of blood letting, purgatives, cold effusion, the induction of premature labour; and the remedies employed, including opium, chloroform, bromides, preparations of iron, zinc, strychnine, and quinine, &c.

After death great turgescence of the brain, shining vegetations in the mitral and aortic valves, softening of

the spinal cord, and ulceration of the intestines appear the chief points of pathological interest. In several cases the urine contained albumen, and there are many other points alluded to in the valuable paper published in Vol. 10 of the "Transactions of the Obstetrical Society."

Soldiers' families constantly on the move, and to a certain extent hardened, appear rarely affected, but in crowded dwellings in large towns, and possibly amongst the fragile scrofulous children of the upper classes, severe cases of chorea will be met with.

Recently a soldier's wife stated that her father was paralysed, that commencing to menstruate at fourteen she caught cold, and for a year suffered from suppression. At the age of sixteen had scarlet fever badly; at the age of eighteen married. When four-and-a-half months pregnant with second child, she quickened on board ship in a fright during a collision, and from that time until delivery, which took place a month after landing in New Zealand, she suffered from attacks of uterine hæmorrhage, and from (what was termed by the 'medical men) St. Vitus's dance. The labour natural, child alive, choreic movements subsided; she was able to nurse and had no relapse.

The following case is at present under treatment:—A pretty, refined, dark-haired, fresh-complexioned, intelligent young woman, slightly built, with good teeth, and those beautiful dark eyes so characteristic of neuralgia. The mother, a sallow dyspeptic, first tells her own story, throwing a certain amount of light on the matter,—namely, that after giving birth to seven children (the pregnancies involving dropsy, and fever occasionally occurring after delivery), her husband deserted her, and behaved badly. But, returning after an absence of six years, was forgiven. She fell pregnant immediately, and her mind brooding, she up to quickening felt an inclination to tear things, to bite, and to jump out of window; however, she controlled herself, deriving relief by taking long walks. The labour natural, the infant after vaccination had an inflamed head; otherwise healthy; dentition easy; no illness later on excepting whooping-cough and repeated attacks of quinsy. This girl, the present patient, commenced to menstruate at fourteen, was extremely regular, and worked hard from morning till late at night dressmaking, living mostly on tea and coffee. As a child she had occasional slight attacks of epistaxis, was of romantic turn, fond of books and music, and of an affectionate disposition.

May 1.—When a little over nineteen years of age the patient marries, and on the 18th menstruates, this period lasting seven days, much longer than usual, and causing great debility.

May 28.—Last evening sleeping alone, her husband absent on duty, she woke suddenly in a fright. The moon was shining into the room, and at the foot of the bed the figure of an absent brother appeared to be standing. The next night husband and wife sleeping together, she was restless, and complained of headache and feeling sick.

May 30.—Walks down to the hospital a distance of half a mile to be re-vaccinated, and in the afternoon was out walking. That night she appeared stupid, half idiotic, twisting and twitching, complaining of flatulence, and during the rain and thunder became almost maniacal.

May 31.—Got up, went down stairs, and contrived to crawl to hospital, where simply complaining of sore throat, was ordered a gargle. That night she did not sleep.

June 1.—In bed all day, very thirsty, drinking tea incessantly.

June 2.—The re-vaccination taking, the twitching increasing. During the night, in her struggles she kicks off the foot-board, but feels no pain. Dr. Prescott sent for. Orders bromide of potassium in ten grain doses. Next day she is rather worse.

June 4.—Admitted into hospital. Is noticed to be all on the work, specially if noticed; understands questions, and although articulation is impeded, replies, each word,

See H. Hecht in the *Gazette Medicale de Strasbourg*; also Forbes, *Vol. II., p. 196.*

as it were, separately shaken out; the pupils are dilated, the eyes inclined to squint, the nostrils inflate, the lips are dry; the movements about the mouth in harmony with the eyes at one moment give the idea of a sneering frown, at another that of intense amusement. The dry fissured tongue is protruded with a jerk, but instantaneously withdrawn. She makes a sucking noise, and although thirsty, dreads the effort of swallowing. Her hair is dishevelled, and she cannot endure the process of brushing, yet she likes to have the eyelids pressed down; likes also to be raised in bed, but soon slips down again. The movements causing no fatigue are symmetrical, but occasionally the right arm is shot out, and the hand previously clenched suddenly opens. The back is wriggled from side to side, and occasionally the body is bent backwards. The skin is cool, the pulse faint 95, the heart's action feeble, but no bruit detected; the urine contains no albumen; the specific gravity 1020; the bowels are confined.

On referring to the detailed notes of the case, it will be sufficient to state the following points were at various times noticed:—

1. Although as a rule the movements ceased during sleep, on several occasions they did not.
2. One day when a gun fired, the movements, especially of the lower extremities, became very violent; another, when a band played, she remained quiet for some time.
3. The bowels and the bladder required constant attention.
4. The vagina narrow and contracted, the cervix uteri elongated, the pelvis very small. No mammary areola. No enlargement.
5. The sense of taste greatly impaired.
6. When asleep, or at times quiet, the cold skin resumed its comfortable warmth.
7. She dreads the dark and solitude, yet when associated with other patients, their groans and sufferings frighten her.
8. At times more resembles a happy silly child than a suffering married woman, and occasionally bursts into tears.
9. Frequently complains of a fixed pain about the centre of the back.
10. Occasionally the characteristic odour of acute rheumatism is noticed about her.
11. Has relapsed twice, and whenever the feet commence to work it is an indication of her being worse.
12. When attempting to walk assisted by the nurse, she has the appearance of a beginner attempting to skate.

Treatment.—Considering the case one of nervous irritation depending on hereditary tendency, anæmia, and the excitement of coition, the bowels were relieved by castor oil and turpentine; moderate doses of chloral at night; sedative liniments over the spine. Iodide of potassium, bromide of potassium, quinine, arsenic, and preparations of iron, have been tried in addition to good nursing hygiene, and simple but nutritious diet. Probably zinc and strychnine, arsenite of iron, cod liver oil, shower baths, and electricity will eventually be useful.

She has been thirty-three days under treatment, and is gradually improving. My fear is of permanent imbecility being induced. We shall see.

NOTE.—July 13. Has been convalescent a week, attends church daily to repeat responses and join in the singing to increase her confidence.

ON HAY-FEVER, HAY-ASTHMA, OR SUMMER-CATARRH.

By ABBOTTS SMITH, M.D., M.R.C.P. LOND.,

Late Physician to the North London Consumption Hospital, and to the Metropolitan Free Hospital, &c.

So many erroneous opinions have existed, and still exist, concerning the peculiar affection known by the se-

veral names placed at the head of this paper, that it appears desirable, in the interests of future accuracy, to enter upon a brief consideration of this disorder, at a period of the year when it is more common than at any other.

First, as regards its causation. It is true that the larger number of cases, as seen in this country, at any rate, arise from the effects produced upon individuals predisposed to it, by breathing air loaded with the odoriferous particles given off from ripe grass, or hay, from which circumstance the familiar name of hay-fever is derived; but as many other agents at times play a part in the causation of this affection, the term hay-fever is in these latter cases a misnomer. Amongst these various exciting causes the most frequent are solar heat (especially the first hot weather of summer), the inhalation of finely-powdered dust (as in railway travelling, driving along dusty roads, &c.), or of powerful irritants, such as pulverised ipecacuanha, and the aroma emanating from different strongly-scented flowers, e.g., beans, lilacs, and elder-flowers, and roses (a), as well as the emanations given off from decomposing vegetable matter, whether of marine origin (sea-weed), or the vegetable products of marshes and stagnant ditches in hot weather. In two instances of this disorder which have come under my notice, the patients were attacked by it in a severe and unmistakable manner when they were on board ship, half-way across the Atlantic, the origin of the attacks being evidently not connected with exposure to the aroma of hay, but with exposure to solar heat. In several cases, occurring in India, and other hot climates, some of the symptoms as described to me by the sufferers so closely resembled those of sun-stroke, that the affection could only be attributed in these cases to the direct action of the sun's rays. In other instances, again, the history of the attacks plainly pointed to malarious emanations from marshes, or stagnant water, as forming both the predisposing and exciting causes of the disorder.

The second point which I shall notice, because no small amount of misconception exists respecting it, has reference to the locality of hay-fever. Some writers, apparently allowing themselves to be misled by the common name of this affection, speak of it as if it were known only in the rural districts of England; assisting further by this mistaken notion to perpetuate the erroneous impression already mentioned that the disorder is solely attributable to the influence of the emanations from ripe grass or hay. But this limited localisation is an idea for which there is no real foundation. Dr. Phœbus, Professor of Medicine in the University of Giessen, and author of an excellent treatise upon hay-fever, has demonstrated its existence in Germany, France, Italy, Prussia, and other European countries; Dr. Dunglison, of Philadelphia, in his work on the "Practice of Medicine," remarks upon the prevalence of summer-bronchitis, as he terms the affection, in the United States, a fact which I can verify from personal observation during a visit to America; and I have also met persons who have themselves suffered, and have noticed the characteristic symptoms in others, in Australia, New Zealand, India, &c. In some parts of Asia this disorder seems to be peculiarly frequent; a patient of mine, Captain C—, who served for fourteen years in Burmah, informs me that it not only occurs in Europeans residing there, but that it is common amongst the natives. This fact may be adduced in support of the statement already advanced in this paper regarding the causation of this affection, namely, that it sometimes depends upon malaria and exposure to the sun's hot rays; the chief causes of its frequency in Burmah being the intense heat, and the malarious atmosphere of the marshy places with which that country abounds. The effects of marsh-miasm as a predisposing, and in some instances an exciting, cause of this affection are recognisable even in England. The average proportion of cases occurring in the fenny, or low-lying, districts is considerably in excess

(a) In some parts of the United States there is an affection locally spoken of as "Rose Fever," and attributed to the smell of the roses in full bloom; I saw several cases of this form of the complaint when I was in America in the summer of 1857.

of that observed in higher and drier localities, while the disorder is occasionally so intimately associated with the more frequent result of malaria, ague, that I have seen the two diseases alternately appearing in the same patient; for a few days, intermittent fever, with its cold, hot, and sweating stages, then, the affection which forms the subject of this paper, with all the well-marked symptoms, feverishness, sneezing, watery discharge from the eyes and nose, difficulty of breathing, &c.

I referred just now to the fact communicated to me upon reliable authority, that the natives of Burmah are subject to this affection, and this allusion brings me to another error, which should be cleared away; I mean the usually accepted notion that this disorder is confined to the upper and middle classes of society. No greater mistake could prevail, and I can only trace it to the obstinacy of persons, who, at first unwilling or unable to recognise it as a distinct affection, have subsequently endeavoured to gloss over this error by professing to regard hay-fever (I use this name in a general sense) as a sort of hybrid, half-real, half-imaginary affection engendered by luxurious habits and whimsical fancies. My experience has led me to a different conclusion. I have seen cases amongst the poorest patients at public institutions, and there is no reason for doubting that, whenever the special predisposition exists, the symptoms will make themselves manifest, whether the individual in question be peer or peasant, delicately nurtured lady, or hard working laundress.

Another great factor of disease, the season of the year, has also been misrepresented in connection with this affection. Somewhat blindly following the nomenclature of the disorder, many think that it never occurs excepting in the summer months. On the contrary, and especially where the sufferer is advanced in life, and the complaint has assumed the asthmatic form, it may be present at any period of the year, or, indeed, continue to torment the patient from one season to another. At the outset, a few weeks constitute the probable duration of the annual attack; in subsequent years, recurring with periodical punctuality, it lasts longer and longer every succeeding summer, until its victim considers himself well rid of it, if it should leave him in September or October after having run a course of several months, whilst in old-standing cases the affection becomes perversely chronic, generally taking the asthmatic form.

Of course, where so many discrepancies of opinion upon various points have long existed, it cannot be expected that uniform views prevail concerning the treatment of this disorder. When, however, we take into consideration the different circumstances connected with the affection, and the various forms in which it shows itself, the febrile, the catarrhal, and the asthmatic, it is evident that the rational treatment will consist mainly in the removal of symptoms and complications as they arise. The general line of treatment which may be laid down is, the administration of the preparations of quinine, arsenic, and iron, when the disorder occurs in persons of weak constitution, or from malaria; of salines and aperients, when febrile symptoms predominate; and of bromide of potassium, aconite, lobelia, and chloral, when the asthma is most troublesome; together with, in all cases, moderate exercise, nourishing, but unstimulating diet, and the avoidance of exposure to the exciting causes of the affection. The mode of the administration of suitable remedies is of the first importance, and, consequently, I have for some years given the preference to the inhalation of medicated spray, where that treatment is practicable, over the ordinary mode of giving medicines, as the affection is principally localised in the naso-pulmonary mucous membranes.

THE LYONS CONGRESS.

The names of Sir Wm. Fergusson, Bart., Mr. Acton and Dr. Cornelius Fox are to be added to the list of members admitted we have previously published.

Hospital Reports.

METROPOLITAN FREE HOSPITAL.

Cases of Albuminuria.

(Under the care of Dr. C. DRYSDALE.)

(Reported by WILLIAM KIPLING, Esq.)

Albuminuria (Syphilitica?)

History.—Morris Mellows, æt. 37, unmarried, occupation, been a soldier in India for ten years, but had to leave the army and come to England three years ago, on account of palpitation of the heart; been a great drinker, chiefly beer and rum. Ten years ago he had sores on his penis at Sheerness, followed in about a month by a rash over his chest, and legs, and sore throat. Whilst at Allahabad was laid up there for four months with rupia of the legs, otherwise been in good health all his life. Present attack came on a week ago with swelling of the face and legs.

April 5th.—*Present state.*—Pulse 80; face and eyelids swollen; legs very much swollen, and pit on pressure; no swelling of abdomen; heart normal. There is a muco-crepitation at the bases of both lungs, chiefly the left, which is also duller than the right. There is a good deal of expectoration of yellow sputa; on left tibia there are several whitish scars, brown at the edges, superficial and not bridled: there is a node on the spine of the right tibia, which came six months ago. Urine acid, contains an eighth part of albumen. Ordered

R Potass iodidi, gr. v.;
Tinct. iodi. ℥ij.;
Aque, ℥j. t. d. s. in a little starch water.;
Pulv. jalap, co., ℥j.;

Omni alter mane,

Lin. sinapsis to be rubbed into back.

April 12th.—Swelling of face and legs greatly diminished; scarcely any pitting of the latter; there is only a trace of albumen in his urine; has cough and expectoration, and still muco-crepitation at bases of lungs. Ordered to the above medicines, a mixture for his cough and hot fomentations to his back.

April 26th.—Node on tibia seems softer; cough and expectoration nearly gone; bases of lungs about normal; no swelling of face or pitting of ankles; faint trace of albumen in urine; is so well that he wishes to return to work. Discharged to be an out-patient.

Albuminuria—Rapid cure.

Thomas Simpson, æt. 33, been a very temperate man, had sores on penis fourteen years ago, no rash or sore throat following.

April 26th.—*Present attack* came on three weeks ago with swelling of legs and face, caused he thinks by exposure to cold.

Present state.—Face pale and puffy; hands and legs a little swollen, the latter pit on pressure; eyelids puffy; the urine on being examined in the usual way by boiling, and nitric acid is found to contain $\frac{1}{2}$ of albumen.

Ordered: Tinct. iodi, ℥v.;
Aque, ℥j. t. d. s.;
Pulv. Jalap, co. ℥j.

Omni alter mane.

May 21st.—Face pale, but no puffiness; no cedema of legs; urine contains $\frac{1}{2}$ of albumen.

May 28th.—No albumen at all in urine, and patient seems in very good health.

NOTE.—This is a most remarkable case, and Dr. Drysdale is inclined to consider that the use of the tincture of iodine has been invaluable in stimulating the kidneys.

Chronic Albuminuria.

History.—Samuel Brown, æt. 35, single, occupation a boiler maker, been accustomed to take six or seven pints of beer a day. Had small-pox when young. Erysipelas of legs seven years ago. Pleurisy three years ago, laid up seventeen weeks with it. Sores on penis fourteen years ago, but not followed by sore throat or rash.

Present attack came on seven weeks ago, with swelling of ankles and legs, does not know of any cause.

April 9th.—**Present state.**—Pulse 80; tongue slightly furred; legs slightly swollen and pit on pressure; no swelling of face; has a little pain in loins; dimness of vision, and on reading for any length of time becomes dazzled; heart and liver seem normal; urine acid contains 1-3rd of albumen; no casts or blood corpuscles.

Ordered: Tinct. iodi, ℥v.;
Aqueæ, ℥j. t. d. s.;
Pulv. jalap, co. ℥j.

Omni alter mane.

April 23rd.—Not much œdema of legs; cannot see very well; urine contains about 1-12th of albumen, and as it has been much the same for the last week he is ordered:

Gallic acid, gr. v.;
Mucilage, ℥j. t. d. s.

April 26th.—Since last report there has been swelling and tenderness of two of the left occipital glands, urine is much the same. As there is a suspicion of syphilis, he is ordered:

Potass. iodidi, gr. x.;
Tinct. iodi, ℥ij.;
Aqueæ, ℥j. t. d. s.

Examination by ophthalmoscope shows nothing very abnormal.

May 14th.—The glandular swellings have now disappeared; urine contains 1-12th part of albumen; slight pitting of legs.

May 17th.—Had a hot-air bath last night, after which he had a good sweat; his legs are not so swollen, but the amount of albumen is not diminished.

May 31st.—Still a little œdema of legs; urine contains about 1-6th part of albumen; his sight is not very good, he can see objects close to, but not at a great distance; pupils are very sensitive to atropine, remaining dilated some days after its application.

Taking: Potass. iodidi, gr. x.;
Tinct. iodi, ℥x.;
Aqueæ, ℥j. t. d. s.

January 10th.—He is so much better, as to desire to go to work; there is very little œdema, and scarcely any trace of albumen when acetic acid is added, and the urine boiled.

NOTE.—Dr. Drysdale is inclined to believe that albuminuria is far more frequently due to syphilis than most physicians think. In one case in which he made a *post-mortem* examination some time ago, at the Metropolitan Free Hospital, there was manifest syphilitic causation of albuminuria, the patient having been covered with rupial spots, and then affected with œdema.

HOSPITAL FOR DISEASES OF THE THROAT.

DR. ANDREW H. SMITH, of New York, exhibited a few days ago, at the Hospital for Diseases of the Throat, an instrument, which is figured in the annexed cut. It is designed to hold the laryngoscope in position in those cases in which both hands of the operator are otherwise employed, as when it is necessary to use the epiglottic pincette and, at the same time, make an application to the larynx by the aid of the mirror.

It consists of a gag (a) similar to those used in staphylophary, with a sort of pincette (c) made of hard-rubber, attached by a pivot to one of the angles, and designed to grasp the stem of the laryngoscope. This pincette has a swivel-joint which permits a rotary movement, while at the same time it moves upon the pivot by which it is attached to the gag. This allows the mirror to be placed in any position.

The advantages of this instrument over others of the same class are its simplicity and cheapness; the ease with which it is adjusted or removed; and the fact that by it the mouth is kept open without a constant effort on the part of the patient.

STUDENTS' COLUMN.

SYNOPTICAL REVIEW OF THE OFFICIAL PREPARATIONS OF THE BRITISH PHARMACOPEIA.

By W. HANDSEL GRIFFITHS, PH.D., L.R.C.P.,
L.R.C.S. Edin.,

Assistant-Librarian Royal College of Surgeons in Ireland.

GLYCERINA (GLYCERINES).

THESE are:—

1. Glycerinum Acidi Carbolici.
2. " Acidi Gallici.
3. " Acidi Tannici.
4. " Amyli.
5. " Boracis.

They are solutions of 1 part of the drug in 4 parts of glycerine, except *Glycerinum Amyli*, in which the proportions are 1 of starch to 8 of glycerine.

In the preparation of *Glycerinum Acidi Gallici* and *Glycerinum Acidi Tannici* solution is aided by means of gentle heat, while in *Glycerinum Amyli* heat up to 240° is gradually applied until the starch particles are broken, and a "plasma" or translucent jelly is formed.

INFUSA (INFUSIONS).

These are aqueous solutions of the constituents of vegetables obtained without boiling. They are prepared by digesting the drug (which is to be cut small, sliced, bruised or powdered) in distilled water for a definite period in a covered vessel and subsequently straining.

Infusion is preferable to decoction, when by the latter process the active principle is volatilised (Buchu, &c.), or a chemical change induced (Senna, &c.)

The following are the official infusions with the proportion of the drug ordered:—

Infusum Digitalis,	30 grains.	
" Quassia,	60 grains.	
" Caryophylli	} ½ ounce.	
" Chiratae		
" Ergotae		
" Rhei		
" Rosae Acidum		
" Serpentariae		
" Valerianae,	120 grains.	
" Catechu	} 160 grains.	
" Lini		

Infusum Anthemidis	} ½ ounce.	
" Aurantii		
" Buchu		
" Calumbæ		
" Cinchonæ Flavæ		
" Cusso		
" Cuspariæ		
" Krameriæ		
" Lupuli		
" Maticæ		
" Senegæ		
" Uvæ Ursi		
" Cascariillæ		} 1 ounce.
" Dulcamaræ		
" Sennæ		

Of the above, all are absolutely simple, except *Infusum Rosæ Acidum*, which has 1 drachm of dilute sulphuric acid added, *Infusum Catechu*, which contains 30 grains of cinnamon bark, *Infusum Lini*, which contains 60 grains of liquorice root, and *Infusum Sennæ*, which has 30 grains of ginger.

The Compound Infusions are:—

<i>Infusum Gentianæ Compositum.</i>	<i>Infusum Aurantii Compositum.</i>
Bitter Orange Peel, 60 grs.	Bitter Orange Peel, ¼ oz.
Fresh Lemon Peel, ¼ oz.	Fresh Lemon Peel, 60 grs.
Gentian Root, 60 grs.	Cloves, 30 grs.
Boiling Distilled Water, 10 ozs.	Boiling Distilled Water, 10 ozs.

In the preparation of *Infusum Lini* the seeds are not to be crushed as the mucilage is contained in the covering. *Infusum Cusso* is directed not to be strained.

Boiling distilled water is used in every case, except *Infusum Chiratae* and *Infusum Cuspariæ*, in which water at 120° F. is employed; while in *Infusum Calumbæ* and *Infusum Quassiae*, cold water is ordered, so that the starch may not be dissolved.

The length of time of infusion varies, and is regulated by the solubility of the active ingredients; it is one hour in the majority of cases; fifteen minutes in *I. Anthemidis*, *I. Aarantii*, *I. Aurantii Compositum*, and *I. Cusso*; half an hour in *I. Caryophylli*, *I. Catechu*, *I. Chiratae*, *I. Ergotæ*, *I. Maticæ*, *I. Quassiae*, and *I. Rosæ Acidum*; two hours in *I. Cinchonæ Flavæ*, *I. Cuspariæ*, *I. Lupuli*, *I. Serpentariæ*, and *I. Uvæ Ursi*; four hours in *I. Lini*.

LINIMENTA (EMBROICATIONS).

Preparations for external use applicable to the skin by gentle friction with the hand or by painting.

They all contain either a fixed or volatile oil or soap, camphor being regarded as a concrete volatile oil.

They may be divided into groups according to their method of preparation.

CLASS I.

Prepared by macerating and percolating twenty parts of the root with twenty parts of rectified spirit, and then adding one part of camphor.

<i>Linimentum Aconiti</i>	} 1 in 1.
" <i>Belladonnae</i>	

CLASS II.

Those of which olive oil forms the basis.

<i>Linimentum Calcis</i>	1 in 2.
" <i>Ammoniacæ</i>	1 in 4.
" <i>Camphoræ</i>	1 in 5.

In *Linimentum Calcis* and *Linimentum Ammoniacæ*, the officinal solutions, are employed, and these reacting with the oil forming a soap.

CLASS III.

Those of which camphor liniment forms the basis.

<i>Linimentum Chloroformi</i>	1 in 2.
" <i>Terebinthinæ Aceticæ</i>	1 in 5.
" <i>Hydrargyri</i>	1 (of mercury) in 6.

Linimentum Chloroformi is a simple mixture of chloroform and camphor liniment; *Linimentum Terebinthinæ Aceticum* is a mixture of one part each of oil of turpentine, acetic acid, and camphor liniment; while *Linimentum Hydrargyri* is made by gentle heating, one part each of ointment of mercury and camphor liniment, and then adding gradually one part of solution of ammonia.

CLASS IV.

Those of which soap liniment forms the basis.

<i>Linimentum Opti</i>	1 (of tincture) in 2.
------------------------	-----------------------

This is a simple mixture of equal parts of tincture of opium and soap liniment.

CLASS V.

Includes the liniments of more complex constitution. The following table will facilitate the recollection of the ingredients of these:—

LINIMENTUM.	ACTIVE INGREDIENT AND STRENGTH.	ORDINARY INGREDIENTS.			EXTRA INGREDIENTS
<i>L. Potassii Iodidicum Sapone.</i>	Iodide of Potassium and Hard Soap. 1 in 9.	Oil of Lemon.			Glycerine and Distilled Water.
<i>L. Crotonis.</i>	Croton Oil. 1 in 8.	Oil of Cajuput.	Rectified Spirit.		
<i>L. Saponis.</i>	Hard Soap.	Oil of Rosemary.	Rectified Spirit.	Camphor.	Distilled Water.
<i>L. Camphoræ Compositum.</i>	Strong Solution of Ammonia. 1 in 4½.	Oil of Lavender.	Rectified Spirit.	Camphor.	
<i>L. Sinapis Compositum.</i>	Oil of Mustard. 1 in 40.	Castor Oil.	Rectified Spirit.	Camphor.	Ethereal Extract of Mezcreon and Distilled Water.
<i>L. Iodi.</i>	Iodine, 1½ in 10. Iodide of Potassium.		Rectified Spirit.	Camphor.	
<i>L. Terebinthinæ.</i>	Oil of Turpentine. 1 in 1½.			Camphor.	Soft Soap.

SPECIAL REPORTS ON FOODS,

INCLUDING DIFFERENT KINDS OF
FARINACEOUS PREPARATIONS FOR INFANTS
AND INVALIDS,
MEAT EXTRACTS, AUSTRALIAN MEATS, &c.,

Together with reliable Chemical Analyses by
Competent Professors.

[PREPARED EXPRESSLY FOR THE "MEDICAL PRESS AND CIRCULAR."]

REPORT ON THE FARINACEOUS FOODS NOW
BEING ADVERTISED AND LARGELY USED
FOR DIETETIC PURPOSES.

(Continued).

DR. RIDGE'S PATENT (COOKED) FOOD, FOR
INFANTS AND INVALIDS.

As professionally certified, it has saved the lives of many, when other diet had failed. Is put up in sizes to suit all classes.

"I have examined and tried Dr. Ridge's Patent Food, and find it a very useful thing for Children and Invalids. It has a great advantage over many articles of diet by possessing an agreeable flavour, and leaving no acidity behind. I often recommend it to invalids because it is so easy of digestion and so very nourishing, and it contains all the elements essential to growth and repair. For young children, and for those whose digestive powers are impaired by loss of teeth or imperfect mastication, this diet is invaluable.

"BENJAMIN GODFREY, M.D.,

"F.R.A.S., M.R.C.S., & L.A.C.,

"Fellow of the Royal Medical and Chirurgical, and of
"the Pathological Societies, &c.

"Carlton House, Enfield, N., July 1st, 1865."

The patentee gives the following account of this food :—

"The 'Patent Food' is prepared from the purest and finest wheat flour, which is subjected for some hours (eight to ten) to an uniform temperature in apparatuses patented by Dr. Ridge, so as thoroughly to cook it and render it more nourishing and easily digestible.

"It is slightly alkaline, and consequently nicely adapted to the plusacid state of the stomach."

Ridge's Food is made from pure wheat, as evidenced by its microscopic examination.

It contains :—

Gluten	12·3 per cent.
Starch, dextrine, &c.	69 "
Ash	1·06 "
Moisture	9·45 "

It gives a slightly alkaline solution, and the ash chiefly consisted of the alkaline phosphates. Although it still contained a considerable number of starch granules intact, there is no doubt that it had been submitted to a heating process; but it was curious to observe that the infusion of this food gave but a slight indication of dextrine. We should feel inclined to urge upon the proprietors the desirability of carrying their cooking process a little further.

This food is sold in packets, holding sixteen ounces, and retailed at one shilling.

LIEBIG'S FOOD FOR INFANTS AND INVALIDS,
GENUINE.

Prepared strictly from the Formula of Baron Liebig by
William Hooper, Pall Mall East, London.

The public are cautioned against so-called superior forms of Liebig's Food, specimens of which have been analysed by Professor Liebig, who reports thus upon them in the *Lancet* :—

"It is impossible that the nourishment can be contained in them which in any way supplies the place of the mother's milk or satisfies the requirements of the infant."

It is therefore essential to observe Mr. Hooper's trade mark upon each package.

Liebig's Food, as originally ordered by that celebrated chemist, consisted of wheat mixed with a small proportion of malted barley. When such a food is submitted in the first instance to a moderate temperature, the diastase of the malt reacting upon the starch converts it into dextrin, and thus makes it into a liquid more suitable for assimilation.

Liebig's Food, as made by Hooper, is sold in one pound canisters at one shilling.

It contained :—

Moisture	10·8
Starch	62·5
Ash	1·731

The remainder of this food was cellular matter, very rich in gluten. The ash was rich in phosphates.

When examined by the microscope, it was seen to consist of wheat and malt in the proportions of about 1 to 4. When made as directed, almost the entire of the starch was converted into dextrin.

THE FOOD FOR INFANTS AND INVALIDS,

Specially prepared by Savory and Moore, Chemists to the Queen, the Prince of Wales, and the King of the Belgians, upon Baron Liebig's principles, approved and recommended by Dr. Hassall and Dr. Lankester,

Surpasses all other substitutes for the natural food of infants, more effectually promoting nutrition and health. Ready for use without boiling or straining.

"A child deprived of its mother's milk can only be fed properly when the food is equivalent in power to that of woman's milk."—BARON LIEBIG.

Directions for Use.—Put one or two tablespoonfulls (not piled up) of the Food into a suitable vessel; mix gradually with two or three tablespoonfulls of fresh milk; add now, with stirring, one-third of a pint of boiling water (or milk). When cool, to the temperature of new milk, it is ready for use.

N.B.—Although not necessary, as above stated, there is no objection to boiling the Food when thought desirable, and the following will be found the best method of proceeding :—The quantities of Food, water, and milk being mixed, the mixture is placed on the fire until the whole thickens. It should then be removed, and stirred until it becomes fluid, when the Food will be ready for use.

The Liebig's Food made by Savory and Moore was put up in ten ounce tins and sold at one shilling.

It contained :—

Moisture	6·8
Starch	68·
Ash	·995

The remainder being cellular matter and gluten,

Examined microscopically, it was found to consist of wheat and malt, and gave similar results when boiled, as regards the conversion of the starch into dextrin, as the previous Food. (This is the proper mode of preparing it.) It differs, however, inasmuch as the amount of starch is higher. This is no doubt due to its being more finely sifted.

Both the two last preparations may be said to fairly represent Liebig's original formula.

REGISTERED FOR TRANSMISSION ABROAD.

THE
MEDICAL PRESS AND CIRCULAR

is published simultaneously in London, Dublin, and Edinburgh, every
Wednesday morning. Price 5d. Post free, 5½d.

POST FREE TO ANNUAL SUBSCRIBERS £1 2 6

" IF PAID IN ADVANCE 1 0 0

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 17, 1872.

THE SEAMEN'S HOSPITAL.

We had hoped that no more scandals would be published to the injury of our charities. But it is to be feared from what we hear that circumstances may yet be dragged forward that will be anything but creditable to the managers of these institutions. In the case to which we shall to-day confine our observations it is a pleasure to report that the affair reflects no discredit on a Medical man.

Dr. Swan has been ejected from an office to which he had been appointed in the usual way at the Seamen's Hospital, and in which he had faithfully served. But we doubt not that when the circumstances become generally known it will be universally recognised that his conduct in the matter was more becoming a gentleman than that of those who have deprived him of his office in a manner unworthy of the petty tyranny occasionally observed in parochial officials. We doubt, too, whether the authorities have not gone beyond their legal powers in expelling Dr. Swan for his very natural protest against a change in the terms of his contract to which he was not invited to accede. At any rate, he deserves the thanks of his brethren for standing upon his professional rights, not to

say dignity; and we trust the subscribers of the Seamen's Hospital will find some means of expressing their disapproval of the conduct of those who have brought this scandal on the charity. The following statement of facts will not fail to enlist the sympathy of the Profession with Dr. Swan. We should be only pleased if the Committee found it impossible to replace him until they had rescinded these obnoxious proceedings.

Dr. Swan only became house-surgeon to the Seamen's Hospital in April last. He then agreed to certain rules and regulations, by which he was responsible to the senior Medical officer. In June the house-governor and secretary assumed the powers held by the senior Medical officer; and the following order was issued by the Committee:—"That in the absence of the Committee the house-governor alone shall be responsible for any departure from the printed instructions laid down for the guidance of the officers of this institution." The usual month's notice on either side had been agreed to. Dr. Swan could, therefore, only protest, and this he did in the following letter:—

"Gentlemen,—I write to protest against your order, which has been communicated to me by Mr. Leach.

"It is universally the case in all hospitals that after a general routine system has been established, suggested by the Medical, and confirmed by the lay Committee, it is left to the resident staff to arrange as to absence and other minor details; and then, if any neglect of duty to the patients occurs, it becomes the secretary's duty to report such to the lay Committee, and for them to take measures such as they may think fit, but in no case that the secretary should interfere with their privileges as Medical officers. Already your restrictions are unnecessarily oppressive. You must recollect that Medical men who have received their diplomas, and are already fitted to take a responsible position in life, are no longer school-boys; and it is not in the nature of things that they should submit tamely to be brought back again to the reminiscences of their earliest boyhood by being obliged to ask a lay official whether they may go out or no. I have been admitted under certain rules and customs, and it now only remains for me to say, that if such an alteration as you propose be carried into effect I shall retire at the earliest opportunity. But let me warn you to take care lest by the increasing irksomeness of your rules you render this establishment wholly distasteful to the Medical Profession.—I am, Gentlemen, your obedient servant,

"WILLIAM SWAN, M.B.,
House-surgeon.

"P.S.—Of course, during the remainder of my stay here I shall adhere to the original rules, and consider myself responsible to the Committee."

What was the result of this? A committee of gentlemen would surely consider this letter, and in the interest of their charity refrain from any exhibition of petulance that might be indulged in with impunity by a representative of bumbledom. But no, the dignity of this Committee must be upheld, and they dismissed Dr. Swan on the spot—a week before his term of office would have expired.

A more disgraceful act it is difficult to imagine; but they went even beyond this, for they tortured his protest into a threat to disobey, as will be seen in the following resolution of June 28th:—"That the Committee having read the letter of Dr. Swan, in which he expresses his intention of ignoring the resolution passed on the 14th inst., and of not conforming to the regulations of establishment, his further services be dispensed with."

The Committee's regard for truth may be judged by comparing Dr. Swan's letter with their resolution,

THE OPHTHALMIC CONGRESS.

THE coming month of August will entice many Medical men to make holiday, and visit London and Brighton. On the first three days of the month the International Ophthalmic Congress will meet at the London College of Physicians. The meeting of the British Association for the Advancement of Science will commence at Brighton on Wednesday the 14th August, on which day Professor Sir William Thomson, LL.D., F.R.S., will resign the chair, and Dr. W. B. Carpenter, LL.D., F.R.S., will assume the Presidency, and deliver an address. The various sections will then meet for the reading of papers at 11 o'clock, a.m., on the 15th, 16th, 17th, 19th, and 20th August. On Thursday evening, August 15th, at 8 p.m., there will be a Soirée; on Friday evening, August 16th, at 8.30 p.m., a Discourse; on Monday evening, August 19th, at 8.30 p.m., a Discourse; on Tuesday evening, August 20th, at 8 p.m., a Soirée; on Wednesday, August 21st, the Concluding General Meeting will be held at 2.30 p.m. On Thursday, August 22nd, excursions will be made to places of interest in the neighbourhood of Brighton.

The *Pharmaceutical Journal* more over informs us that the meeting of the Pharmaceutical Conference for 1872 will be held in the Royal Pavilion, at Brighton, under the presidency of Mr. H. B. Brady, F.L.S., F.C.S. On Tuesday, the 13th, at 10 a.m., the President will deliver an address; the reading and discussion of papers on pharmaceutical subjects will then commence, be continued in the afternoon till 4.30, and be carried on during Wednesday; an adjournment from 12.30 till 2.0 each day.

In the interval between these meetings, the Annual Meeting of the British Medical Association will be held in Birmingham, on the 6th, 7th, 8th, and 9th of August, under the Presidency of John Whipple, F.R.C.S., Consulting-Surgeon to the South Devon Hospital. An Address in Medicine will be delivered by Samuel Wilks, M.D., F.R.S., Physician to Guy's Hospital; and an Address in Surgery will be delivered by Oliver Pemberton, Esq., Professor of Surgery in Queen's College, Birmingham.

The business of the (five sections) Annual Meeting will be conducted under the presidency of the following gentlemen, viz.:—Medicine, Dr. Bell Fletcher, Birmingham; Surgery, Sir William Fergusson, Bart., F.R.S., London; Midwifery, Dr. Evory Kennedy, Dublin; Public Medicine, the Rev. Dr. Haughton, D.C.L., F.R.S., Dublin; Psychology, Dr. Maudsley, London.

All the meetings in connection with the Annual Meeting will be held at King Edward's School, New Street. On Tuesday, August 6th, will be held the First General Meeting; on Wednesday, August 7th, will take place the Second General Meeting, and the address in Medicine; there will be also a public luncheon in the Exchange Assembly Rooms; 2 p.m., Meetings of Sections, Exchange Assembly Rooms—adjourn at 5 p.m.; and in the evening the President's Soirée in the Town Hall; on Thursday, August 8th, the Third General Meeting, the address in Surgery by Professor Oliver Pemberton, Surgeon to the General Hospital; 1 p.m., public luncheon—Exchange Assembly Rooms, and a public dinner; and on Friday, August 9th, the Concluding General Meeting.

On Friday and Saturday excursions will be arranged to visit (1) Dudley Caverns, and Lord Dudley's Ironworks; (2) Stoke Salt Works, the Sanatorium, and the Lickey Hills; (3) Warwick, Leamington, and Kenilworth; (4) Stratford-on-Avon.

On Friday a Flower Show will be held at the Botanical Gardens, Edgbaston, to which members of the Association will be admitted on presenting their cards.

Up to the present the railway companies have refused to grant any extra accommodation to the members of the Association visiting Birmingham.

SURGERY OF THE FRANCO-GERMAN WAR.

(Continued from page 31.)

VII.

VII. Daily Routine of the Ambulance.—7 a.m., déjeûner of the sisters and infirmiers; 7.15, matins by the sisters; 8 to 8.15, déjeûner of the wounded; 8.15 to 8.30, toilette of the wounded; 8.30 to 11.30, first attendance by the Medical officers, assistant-surgeons, &c.; 11.30 to 12, dinner of the wounded; 12.30 to 1, dinner of the infirmiers; 1 to 2, dinner of the sisters; 2 to 5, reception of visitors; 5 to 6.30, second attendance by the Medical officers and the assistant surgeons, &c.; 6.30 to 7, supper of the wounded; 7 to 7.30, supper of the infirmiers; 7.30 to 8, supper of the sisters; 8, vespers and bed.

VIII. Medico-Chirurgical Service.—The Medical Director of the ambulance, with the concurrence of the surgeons, and with reference to the season and circumstances, will fix the hours of the visits and consultations, as well as those of the daily service, which morning and evening devolve upon the surgeons.

The assistant-surgeons will regularly, in the morning after the déjeûner of the wounded—i.e., 8.30, and in the evening at 5, attend to the wounded allotted to them by the surgeons.

In extraordinary cases it will not be necessary strictly to follow the fixed times established for the visits and the treatment.

During the visit and the dressing no one except the sisters and the infirmiers, has the right to stay in the buildings of the ambulance, unless his presence is justified by his assistance.

The infirmier-en-chef is expected to be present at the visits and at the different Medical and surgical operations. During this time the sisters will hold themselves in readiness for any service which may be assigned to them for one bed or another.

All special prescriptions and distributions of medicaments, linen, food, drink, tobacco, delicacies of all sorts, will be subject to the order of the surgeons.

The sisters and the infirmier-en-chef, according as the surgeons may direct, shall be personally responsible for the punctual execution of the above-mentioned distribution.

Statistics and results, in a scientific point of view, will be registered on proper forms, and will be published every two months.

IX. Operating Room.—*Surgical Operations*—It is not permitted to any one, except those admitted or invited by the surgeons, and to the *personnel* appointed by them for each operation, to be present at the operations, nor to enter the rooms in which they are taking place.

X. Ambulance Dispensary.—The surgeons, assistant-surgeon, the paymaster, the steward, the sisters, and the infirmier-en-chef have alone the right of entry into the dispensary.

It is forbidden to take or deposit anything in the dispensary, except under the orders of those above mentioned.

The surgeons and assistant-surgeons alone may give prescriptions for medicines to be drawn from the dispensary.

The person charged with the execution of the instructions of a Medical officer will be responsible in regard to it.

XI. Baths.—No bath may be given to the wounded without the orders of the Medical officers.

The surgeons and assistant surgeons will personally ascertain the temperature of every bath ordered.

The infirmiers shall not place a wounded man in a bath, or take him out, without having previously consulted the above authorities.

XII. Heating, Light.—At present the temperature to be maintained in the buildings of the ambulance during day or night, will depend upon the exterior temperature, the sun, the wind, &c.

The infirmier will regulate the temperature by opening or closing the curtains as well as the windows opposite.

At sunset the lamps will be put in their proper place throughout the hut, and those outside lighted. At 9 o'clock p.m. it is prohibited to every one either to talk aloud, to read, or to smoke in the huts.

The infirmier-en-chef, the infirmiers, the firemen, and the lampists are strictly requested to take the necessary precautions against fire.

XIII. Ventilation.—The measures relative to ventilation and to the opening of the curtains, windows, &c., will be directed, under the instructions of the surgeons, by the infirmier-en-chef, and put into execution by the infirmiers and the "manœuvres-rideaux."

The infirmier-en-chef is directly responsible for the proper execution of the instructions of the surgeons.

XIV. Closets.—A fatigue man is especially charged with the duty of cleaning and disinfecting these places; the infirmiers will take every care to avoid wetting or soiling these places unnecessarily. It is forbidden to deposit here the remains of dressings or used charpie. All these shall be thrown in a place appointed for that purpose.

XV. Day and Night Service.—In the huts, the daily service will be carried on by two sisters and two infirmiers in each hut.

The night service will be carried out (the infirmiers being relieved every 24 hours) by an infirmier in each hut.

The infirmier-en-chef is charged with the inspection of the infirmiers, day and night, in all the huts. All must conform to his orders.

The placing and transfer of the wounded from one bed to another, or the changing of position in bed, must be done under the orders of the surgeons.

It is needless to remind the infirmiers to use the politeness and civility due to every one, but most particularly to those men who have exposed themselves and who have been wounded themselves for the honour of their country.

The books provided for the relaxation of the wounded will be carefully replaced in the library in one of the huts of the sisters.

XVI. Cleanliness of the Huts.—The infirmiers are strictly responsible for the cleanliness of the huts. Immediately after the morning and evening dressings, they will carefully clean each hut. This cleaning will occupy ten minutes. The passages will be dusted and swept daily.

During great heat the floor will be sprinkled with water, also the curtains.

Utensils such as covers, dishes, glasses, &c., the "urinoirs," the "vases de nuit," must be kept constantly in a state of cleanliness.

The furniture, tables, chairs, benches, shall be carefully dusted and kept clean.

The cleanliness of all the appurtenances of the ambulance, windows, doors, &c., must be maintained day and night—of the flooring particularly, and of the crockery in general.

The remains of charpie, tobacco, cigars, or cigarettes, empty bottles, &c., must be immediately removed. Bands, bandages, napkins, and other linen capable of being washed will be carried immediately after use to the shed set apart for the purpose of receiving them.

With regard to the articles to be thrown away, such as used charpie, they will be buried in the place appointed for that purpose.

The infirmiers, as well as the infirmier-en-chef, are

always responsible for the cleanliness of the huts, of the ambulances, and of all objects therein, while the sisters will attend exclusively to the cleanliness of the wounded, of their linen and bedding.

It is permitted to the wounded to smoke during the day, except during the hours of dressing and repose.

The wounded are requested to use while smoking every precaution against fire.

The sisters and infirmiers will watch the proper execution of this instruction.

Permission to smoke is not given to those who visit the wounded, nor to the infirmiers.

XVII. Dead-house.—Every case of death must immediately be notified by the sisters or infirmiers, to the surgeons or assistant-surgeons.

After having confirmed the decease, the surgeons will see that the dead body be transferred with due decency to the dead-house.

The effects left by the deceased will immediately after death be collected by the sisters and infirmiers and handed to the paymaster. The latter will take care to have the body removed and interred.

The effects left by the deceased will be consigned, against a receipt, to the military hospital appointed for the purpose.

XVIII. Linen and Washing.—The directress of the laundry will furnish, from the principal depôt of the small assortments of the sisters, the necessary quantity of linen for the carrying out of the surgical duty of the wounded without delay.

The delivery of soiled linen for washing, comprising bandages, mattresses, pillows, cushions, &c., as well as the reception of the clean linen, are in the province of the directress of the linen-store, and for which she is held responsible.

The General Council for the direction of the ambulance will provide the linen for the ambulance through the central linen stores of the Société de Secours aux Blessés, and also for all other provisions.

XIX. Kitchen.—The cooks will receive daily supplies from the steward.

The cooks will every evening make out a menu for the next day, in accordance with the instruction of the Medical Director of the ambulance. This menu will be entered in a special book, and a copy will be displayed in the kitchen.

The cooks are responsible for the proper preservation and feeding of the live-stock destined for the food of the wounded.

They will be assisted by an assistant-cook and by two men, one for out-of-door work and the other for the scullery.

XX. Cellar, Meat Safe, and Stores.—The cellar and the provision stores are placed under the exclusive surveillance of the steward and purveyor.

They are alone responsible to the Director, and alone keep the inventory, and alone have the right to receive money and make disbursements, under the obligation of having to keep their books of accounts correctly.

XXI.—Purchases and Distributions of all Sorts.—No one has the right to make purchases or distributions, &c., without the order or acquiescence of the Director. Every purchase must be paid for in ready money after entry and always against a receipt.

XXII. Receipt or Delivery of the Objects which arrive at and leave the Ambulance.—The letters, journals, photographs, packets of all sorts will be handed to the paymaster after their receipt, by whomsoever they may be received.

The articles specially directed to the ambulance will be received exclusively by the surgeons, the paymaster, or the steward: their receipt alone is valid.

XXIII. Requests for Information, Receipts, Orders for Payment, &c., Reports, Statements, Official Lists.—The Director has the sole right of receiving, signing, and forwarding these, or of ordering others to do so.

A placard is placed at the side of each bed. It gives every desirable information of the wounded.

Besides this, lists of the wounded and of changes happening in the ambulance will be made from day to day and furnished by the paymaster of the ambulance.

A detailed list of the wounded is left with the paymaster, and will be constantly rectified for the accommodation of visitors.

XXIV. *Special Cases* are regulated by special rules: the duties of the paymastership, stewardship, the exterior lighting, the arrangement of the curtains in the eight huts, the wounded, the pumps, the night watching, the day inspectors, the orderlies, the sweepers, the closet-men, the night-men for the removal of all refuse, the stables and the coach-house, the operating room and dead-house, and lastly, the water service, the reservoirs, and the bells.

Special instructions are made for the kitchen service and that of the cellar which contains the extras for meat and drink, the linen service, the provision stores, and the ice-house of the Château of St. Cloud.

In case of any extraordinary accident, or when it is necessary immediately to give information, advice, or to lend assistance, it will be necessary to inform without delay, at any hour day or night, the surgeons, the paymaster, or the steward, and to call them at need.

The Director holds personally responsible every one belonging to the ambulance for the strict execution of the precautions to be taken to avoid the danger of fire.

Notes on Current Topics.

IA Conjoint Examining Board for Ireland.

We have great satisfaction in the announcement that the Irish licensing authorities have come to an agreement on a scheme for a Conjoint Examining Board. The plan agreed to by the conference of delegates was, as our readers are aware, under debate in the College of Physicians for some weeks, and we are informed that it has been adopted with unimportant modifications. The Queen's University is now the only Irish Medical authority which declines to co-operate in any arrangement for educational or examinational reform. The Scotch bodies have agreed to a sort of pretence of examination, which runs no chance whatever of approval either by the Medical Council or the Government, and there can be no reasonable doubt that if the matter should come before the House of Commons, or pass into the hands of Government, the efforts of the principal licensing bodies of England and Ireland to carry out an honest measure of reform will meet with approval, notwithstanding the abstinence of the Scotch and one Irish corporation.

New Regulations in the University of Dublin.

THE University of Dublin has made a recent alteration in their regulations, which is a very judicious one, and will add considerable prestige to their Mastership in Surgery. Hitherto that degree was given as the ordinary qualification in Surgery of a Bachelor of Arts, there being of late years no lesser diploma nor any higher surgical qualification. The Board has now made the Mastership the companion of the Doctorate in Medicine, to be obtained only after the expiration of three years from the qualifying of the candidate. The lowest surgical qualification for a graduate in arts will in future be the Bachelorship in Surgery, which will involve the entire curriculum hitherto necessary for the M. Ch.

Prescriptions Written and Read.

A VERY painful case of poisoning which occurred last week at Morecambe has called attention, not only to the occasional looseness of practitioners in the writing of their prescriptions, but to the rational reliance which the law should put in the discretion of the dispenser who makes it up. A poor woman who suffered from dropsy was seen by Mr. Metcalfe Johnson, the local surgeon, who prescribed a grain of morphia with the direction, "fiat pilulæ lex." The assistant who made up the prescription read the direction as "fiat pil. j. nutte taelæ lex," while Dr. Johnson says he meant it to signify "divide in pil. ij." The patient took an entire grain of morphia and died, and the jury found a verdict of death by misadventure, which was equivalent to an acquittal of the assistant.

In this particular instance we can approve of the view taken by the jury, inasmuch as it appeared from the evidence that the accused was competent, experienced, and careful, and the Latin instructions to him rather inexplicit. But we cannot allow it to be understood that a dispenser is absolved of all responsibility if he carries out the written directions of the prescriber. The knowledge of the dispenser is the proper check against possible errors in the prescription, and the public expects in him such an amount of intelligence and experience as shall protect them from the effects of such "misadventure." In this case the dose of morphia given was not obviously poisonous, and it is possible that the assistant may not have seen cause for his interference, but as a general rule it must be assumed that a dispenser shall bring knowledge and attention to his work, and if he does not possess such qualities, his employer cannot be held free of blame if he dispenses a prescription which is plainly dangerous.

The Bruit de Diable, or Anæmic Murmurs.

In a lecture by Dr. A. Duchek, Professor of General Pathology in the University of Vienna, notes of which were taken by Karl Wavlik, and have been translated for the *Medical Examiner*, we take the following:—

There are to be found murmurs in the heart and the veins, which do not arise from any substantial organic changes in the heart or vessels, as for instance in men and animals exhausted by loss of blood and attendant anæmia. In the same degree as the loss of blood and the paleness of the skin proceed, these murmurs appear in the heart and the veins of the throat. In severe cases if we touch the jugular vein with the finger we perceive at once a continued vibration like that of a string. On pressure on the upper part of the jugular vein, both the perception of the vibration and the acoustic evidence of a murmur disappear, proving it to be merely venous.

The formation of the heart sounds is modified by two circumstances: the condition of the valves of the heart and the vessels on the one hand, and the pressure produced by the blood stream on the other. As we have in such cases of anæmia no symptoms permitting us to diagnose changes in the vibrating mediums, we are induced to seek for the origin of these sounds in the causes themselves which produce vibration, viz., the pressure of the blood. In the disorders attended by these murmurs (as anæmia, chlorosis, and loss of blood), the propulsive power of the heart is unchanged, but its contractions are more frequent, while the blood is either diminished in quantity or weakened in quality. The pressure exercised by it in the circulation is also diminished, so that the impulse given by the blood column is not sufficient to develop in the valves, or in the arterial walls, the amount of tension necessary for the formation of the sound, which under

normal circumstances makes its appearance in these vibrating mediums, but in these cases is lowered into the acoustic impression of a murmur.

In this way we explain the origin of these murmurs in the heart. It is more difficult, however, to trace its course in the jugular vein. Some have attributed it to the arteries, but this is contradicted by its disappearance on pressure on the jugular vein, as well as by its continuity. These sounds are modified in two ways. They grow stronger at regular intervals, being reinforced by the sounds of the carotids; we call these *moments of reinforcement*. Secondly, the murmurs are increased or diminished according to the force and rapidity of the respiration.

In the heart we attribute all sounds and murmurs to the action of *vibrating membranes*. But for these murmurs in the veins we cannot suppose that they are caused by a *whirl of blood*, nor by the pushing of the blood stream against a narrow entrance. Behind the insertion of the sterno-cleido-mastoideus the jugular vein is wider than elsewhere, forming the bulbus, and beneath this bulbus, in the narrowest part of the vein, are valves. These valves have a most important influence upon the entire circulation. If the pressure in the thorax is too great they are approximated and thus oppose the further entrance of the blood. The part of the veins above them becomes, consequently, dilated just as in cases of stagnation in the heart, the jugular vein is distended and the jugulum grows gradually more shallow.

The venous murmurs then arise from the vibration of these valves caused by the impulse of the blood. When the blood flows slowly the impulse is too weak and no murmur is to be heard. The murmur arises when the valves are half opened and put into vibration by a sufficient rush of the blood.

Another peculiarity is to be noted. The bulbus is attached to the clavicle, behind the sterno-clavicular articulation, and thus being stretched out, the flow of blood is facilitated. If the pressure in the thorax is increased by valvular failures, emphysema of the lungs, &c., the stream flows slowly, and, therefore, we do not find these murmurs attending disorders of the intra-thoracic organs. Another consequence of this fact is, that these murmurs disappear in anæmic persons when they become affected by pneumonia or exudative pleurisy, reappearing again, however, on recovery. The two necessary requisites then, for the production of the murmur are a speedy circulation, and a normal pressure of blood in the thorax.

This view also affords us an explanation of the fact of the murmurs growing stronger when the respiration is more hurried. The thorax being strongly dilated, the blood rushes into it in more forcible currents, thus strengthening the acoustic impression. When the respiration is impeded, or is forced, the circulation loses the necessary rapidity, and the vibrations become inaudible.

These murmurs are very rarely to be found in connection with mechanical changes in the heart. They accompany similar murmurs at the aorta, which are always systolic, never diastolic. They may perhaps be diastolic in the most severe disorders of this kind, where it is impossible to distinguish whether there is only one continued murmur, or whether the systolic and diastolic murmurs meet and run into one another.

Granulations of the Conjunctiva Treated by Electricity.

Two methods of treating granulations of the lids by electricity are noticed. Dr. Kohn, of Berlin, employed a battery of one element. Having protected the eye with Jaeger's plates, he placed the heated platinum wire on the eyelid. Dr. Schivardi employed a Bunsen battery of two elements. The negative pole is applied to the inverted surface of the upper lid by means of a buttoned sound. The positive pole is applied to the nucha by means of a sponge saturated in salt water. The session is of about ten minutes duration. Remarkable success is claimed.

Capsuled Volatile Remedies.

THE use of capsules to enclose precise doses of nauseous medicaments is likely to become more general by the introduction into this country of Dr. Clertan's carefully made "pearls" from France, where they have long been highly esteemed—Trousseau and Pidoux, and other authorities having highly recommended them. These "pearls" are quite models of what such a preparation ought to be. Any one may convince himself that their contents are what they profess to be by bursting one of them. Slight pressure between the thumb and finger suffices for this, dispersing the ether, chloroform, &c., through the air, and leaving the envelope for examination, when it is found to be fine isinglass. The "ether pearls" are very important. Each contains about five drops of pure ether. In a few seconds after it has been taken the isinglass is dissolved in the stomach, and a feeling of warmth is perceived as the first effect of the escape of the ether. The same holds good of chloroform. We have taken these ourselves, and given them to patients with much satisfaction.

The "pearls" of valerian, turpentine and assafœtida, enable us to give these nauseous medicines to the most fastidious invalids. Any one who hesitates about the quality of the drug has only to rupture a pearl in the manner we have related and he will be convinced by the sense of smell.

Summer Drinks.

AERATED waters should have their chance now, if at any season of the year. Accordingly, soda water, lemonade, and other drinks meet us at every turn. Where alkalies are desirable, a free indulgence in these is of a certain value, and it is not difficult to discriminate between the cases likely to be benefited by soda, potass, lithia, &c.

It however sometimes happens that patients who ought to take acids are desirous of aerated beverages. For their benefit we may mention that Messrs. Blake, Sandford, and Blake, make aerated mineral acid water, and aerated phosphoric acid water. The former contains twenty drops of diluted nitro-muriatic acid in each bottle, and is therefore a most useful remedy. We believe these acid waters were first made by Messrs. Blake for some members of the Royal Family and they are becoming quite popular.

Good Fortune of the Massachusetts General Hospital.

THE *Boston Med. and Surg. Journ.* announces that a few days ago the treasurer of the Massachusetts General Hospital received for the large sum of \$446,000, which was paid to him as the result of a provision of the will of the late John Redman. Mr. Redman died some twenty years since, leaving a will by which the hospital was made the residuary legatee of his estate upon the death of a son who had a life interest in it. The advance in both real and personal estate since that time has increased the value of the legacy from the \$50,000, which the trustees of the institution once expected to receive, to nearly half a million.

The Windsor Barracks.

WE take the following from an article in the *Berkshire Chronicle* which appears to call for some explanation, and which we therefore commend to those whom it concerns:—
"When we reflect for a moment that a regiment like

that of the Royal Horse Guards, the *élite* of the British army, and a costly luxury to the ratepayers, has been unnecessarily exposed to the effects of bad drainage, &c., what may Her Majesty's other regiments look forward to, as certainly no surgeon will venture a sanitary report in future until he can substantiate his views with a death or two—such is known to be the opinion and decision of the surgeons of the general army. The case stands thus:—The barrack, particularly the officers' quarters, was reported unfit for occupation by Surgeon Major Logie, of the Blues, an officer of 31 years' service, his report being supported by two other Medical officers of the Household Brigades (their combined services amounting to upwards of 67 years). What follows? A board composed of a lieutenant of Engineers—the Royal Engineers—and a staff surgeon of 18 years' standing, were sent five days after to inquire into the accuracy of Mr. Logie's report, he being ordered to wait upon those two young gentlemen. The result was that three weeks after a severe reprimand was handed to Surgeon Major Logie, stating his report, "causing much anxiety, trouble, and correspondence, had not been substantiated, and had resulted in no proof, and coming from an officer of such long standing was shorn of much of its value." Such was the decision and censure of Sir Thomas Logan, K.C.B., Director General Army Medical Department, based upon the report of those two young gentlemen. Luckily for the Blues, they have for their surgeon a gentleman of experience and thorough independence. Surgeon Major Logie took immediate and most active measures for killing the poisonous effects of those drains, &c., in and about the officers' quarters (in which house about a month before an officer of the previous regiment had narrowly escaped with his life from typhoid fever). Notwithstanding these constant efforts, two officers and one non-commissioned officer were seized with symptoms of a typhoid character. Yea, proofs are not wanting to substantiate the forethought, experience, and zeal of Surgeon Major Logie, both officers and men coming forward to vouch, in the strongest language, for his statement in the first instance. Too much credit cannot be given to Mr. Logie for his care and the active line of conduct he has shown towards his regiment, at the same time never having acted without the knowledge of, or expressed approval of, his commanding officer, Colonel Baillie; and we can confidently say that had it not been for his constantly employing disinfectants in all shapes, stopping the use of water which became contaminated with organic matter, and also his causing all the fresh supplies of water to be filtered, for both cooking and drinking purposes, the chances are that that fine regiment would have been rendered totally unfit for duty."

Special Report on Diseases of the Throat.

TO-DAY we begin another of those Special Reports for which this journal has long been distinguished. The clinical character of this new report and the reputation of its editor, lead us to hope it will equal its predecessors in interest and value. Dr. Prosser James was the first physician who employed the laryngoscope in this country, and his work was the earliest in which its uses were described. Moreover, he may claim to be the father of laryngoscopical medication, for, long before Türch or Czermak had turned their attention to the subject, he had succeeded by the aid of a primitive instrument of his own constructing in curing a patient by local treatment. All his writings, both in this journal and elsewhere, have been characterised by a scrupulous anxiety to be impartial and to do justice to every one. We, therefore, feel sure that no better authority on the subject could be found to pass in review its literature, especially when we remember that years of foreign travel have made him familiar with the practice and languages of our continental *confrères*. If we

lose some of his services in Medical politics we are glad to enrich our columns with his clinical work.

Those desirous of bringing under his notice their inventions or writings can address them to either of our offices or foreign agents, or by post direct to Dr. Prosser James, 18 Dover Street, Piccadilly, London.

Public Health Bill.

THE debate on this measure, though a very important one, was not—being principally on financial subjects—of much special interest to the Medical Profession. In his opening remarks, however, Mr. Stansfeld let fall some observations which are worthy of close attention by our readers. He said,—

The measure proposed that the Imperial treasury should bear half the salary of the Medical officers of health to be appointed under the Bill, stipulating that as Government was to bear that proportion of the salary it should be entitled to share in the appointment; and he hoped this joint appointment would be the rule rather than the exception. If the Government were to be partners in payment it should also be partners in the appointment and partners in dismissing; that was to say, when an appointment was made the consent of Government should be asked, and no officer should be subject to dismissal without the sanction of the Government or the Local Board. Next to the Medical officer of health, the most useful officer was the sanitary inspector. It was of the greatest consequence that the local authorities should be encouraged to appoint a sanitary inspector, and that he should be a man free from capricious dismissal, and at liberty to perform the duties which the legislature had imposed upon him. With these views he proposed to ask Parliament to contribute one-half of the salary of the sanitary inspector also. These three features—the lending local boards at 3½ per cent., the payment of half the salary of the Medical officer of health, and the payment also of half the salary of the sanitary inspector, constituted the principal proposals of the Bill.

Sir M. Beach thought when the time came for the house more fully considering this important question, it might very fairly be argued that the whole instead of the half of the salaries of the officers of this character should be paid by the Treasury, and that nothing at all should be paid from the rates. The house would recollect that, as a matter of practice, the salaries paid to these officers were not within the control of the local authorities. They would wish to raise or lower the salaries paid to them, but they had to apply to the Local Government Board previously for their consent. And seeing the Local Government Board exercised this control, they would be put to no risk of the local authorities dealing with the money of the Imperial exchequer in the way they might be disposed to deal with it if at liberty to spend it as they chose. It was satisfactory, however, that the right hon. gentleman had gone as far as he had done.

Mr. Corrance regretted that a Bill equal in importance to any which had been before the house should have been delayed to the end of the session. He thought it was a most incomplete and imperfect measure. The right hon. gentleman had told them that his present proposal was only provisional; that was, that the main point and pivot on which the Bill turned was only provisional. That fact ought to be considered. Then, as regards its nature, he thought its operation would be only partial.

Dr. Brewer believed it would be most important that the Government should encourage the idea of Medical officers being appointed, not merely for a parish or union, but for several parishes, unions, and even districts. They did not want Medical officers to be mere inspectors of nuisances, nor did they want them to make reports upon all sorts of subjects. The special function of a Medical officers should be to report, not only upon the special cir-

cumstances of his own district, but so to concentrate his attention upon all the sanitary peculiarities of the locality as to be able to make suggestions to the central office for them to carry out in connection with the Government for the improvement of the sanitary condition of the people.

After an effort by the opposition to postpone the Bill to next session, the antagonism was eventually withdrawn, and the debate adjourned.

The Long Bow.

In the *Philadelphia Medical Reporter* of May 25, we find a case of *soi disant* puerperal convulsions, reported by a Dr. Schumo, of New Jersey. He says:—The girl (for she was but a child), was lying in bed with her arms pinioned, breathing stertorously and totally unconscious; her pulse gave but little evidence of her alarming condition, it being normal as to number of beats and volume. I immediately bled her to the extent of about three pints. After taking over a quart of blood, she gave some evidence of returning consciousness, but doubling the propriety of stopping at that quantity, I let the stream flow until the pulse flagged. I left the house before she was able to articulate sensibly.

Truly, the Medical theorising of late years has accustomed us to the exercise of an abundant credulity, but we admit that we—to use the Gladstonian phrase—require to be “educated up” before we can gorge and assimilate the record of puerperal convulsions, occurring three days before labour, in which the practitioner, in presence of a pulse “normal as to beats and volume” bled the patient to a measured quart, and a further indefinite quantity; “until the pulse flagged.”

A New Means of Combatting Muscular Contraction.

EVERY one is familiar with the resistance offered by muscular contraction in the reduction of dislocations or of fractures with displacements of the fragments. In order to avoid this difficulty, resort is had to reduction as soon after the accident as possible to profit by the condition of stupor existent at that time. After this period etherization becomes necessary. M. Broca has devised, says the *Lyon Médicale*, a means which is void of the inconveniences of anæsthesia; it is compression of the principal artery of the wounded limb. The muscles deprived of the blood necessary for the exercise of their functions by compression of the brachial or femoral arteries are unable to contract.

A New Method of Arresting Epistaxis.

DR. F. MARIN, of Geneva (*Journal de Méd. et de Chir. Prat.*, May) has discovered a new and simple method of arresting hæmorrhage from the nasal cavity. It consists in applying pressure to the facial artery at a point immediately beneath the ala of the nose, where the vessel can be pressed against the superior maxillary bone. In epistaxis the hæmorrhage is usually confined to the anterior third of one of the nasal fossæ, and as pressure upon the facial artery causes a diminution in the flow of blood to this cavity, the hæmorrhage is arrested almost immediately, and this proceeding is therefore recommended as preferable to that of plugging the posterior nares by the aid of Belloc's sound, in attempting which the surgeon is generally pretty thoroughly smeared with blood, and is not

unfrequently bitten. Dr. Marin has had occasion to give numerous trials to this method suggested by him, and has generally found it effective. In two instances where it failed, plugging the posterior nares was attended with like result.

THE fiftieth anniversary of the foundation of the Royal Society of Medical and Natural Sciences at Brussels, is about to be solemnized by a great assembly of the Profession in that city, which representatives from all parts of the Continent have notified their intention of attending.

WE are threatened with a “bakers' strike;” if it takes place it will be, indeed, a serious matter, especially for the poor. As well as the twelve hours, &c., the journeymen bakers now require, they absolutely need lifting up above the mere drudgery of their unclean, repugnant, and unhealthy labour, as the manufacture of our daily bread is of vital importance to the whole community, together with the life and death of many thousands yearly of journeymen bakers. We once more call attention to the facts elicited before a Committee of the House of Commons. Dr. Guy found that 108 bakers out of 111 were actually diseased, and many other items went to show the unhealthiness of these men. When will machinery universally be employed?

Special Report

ON

DISEASES OF THE THROAT.

Edited for the “MEDICAL PRESS AND CIRCULAR.”

BY PROSSER JAMES, M.D., M.R.C.P.,

Physician to the Hospital for Diseases of the Throat and to the North London Consumption Hospital; Lecturer on Materia Medica and Therapeutics at the London Hospital.

THE object of the present series of reports is to bring together, for the convenience of the readers of the *MEDICAL PRESS*, a mass of material in reference to the subject that has accumulated in my hands during the last few years, and at the same time to keep them *au courant* with a branch of practice that has made, and is making, rapid and steady progress. For this purpose it will be necessary to pass in review a considerable proportion of the literature of the subject. This review cannot, however, be exhaustive. It must be not only incomplete, but fragmentary, particularly as it is continually receiving fresh and important additions. I shall therefore not pretend to follow strictly any classification, nor shall I scruple to return to a subject previously considered, should new contributions seem to call for remark.

I do not even promise to criticise all the views to which I may have occasion to refer, but will endeavour to represent them correctly, and should I misapprehend any author, shall feel grateful if he will kindly correct me.

In not a few cases I shall merely reproduce the writers' own words, though in the majority abridgment will be absolutely necessary. From this it will at once be seen that a finished work is not my intention, and considerable latitude of arrangement may therefore be permissible. My reports will, in fact, be but a selection from the gleanings I have made during a long series of years in this depart-

ment of Medical study. Should I be able to carry them on for some time, they may perhaps be looked upon in the light of *mémoires pour servir*, a branch of literature but little represented by English journals, but which is so striking and useful a feature of our French contemporaries.

This much being premised, a word or two will suffice to indicate the scope of these reports.

It was at first intended to extend them to all diseases of the respiratory organs, but the great extent of such a subject would utterly forbid my passing in review anything but the most recent contributions to the subject, and I have therefore determined to limit them to a narrower sphere. Still, "Diseases of the Throat" will be understood in its widest sense, so much so that I shall not scruple to speak of diseases that are closely allied to those usually passing under that name. It is not as a specialty that I propose to deal with the subject, but simply as a convenient branch of practice. Some writers limit their attention to a single organ, the larynx, the pharynx, and so on. A very convenient division of our subject may thus be obtained, but such a classification would not serve my purpose. If compelled to divide my subject in that way, I should rather treat first those diseases affecting the mucous membrane. It is, in fact, to them I shall invite first attention, and that for several reasons—among others, that it is with this membrane that we have chiefly to do in the majority of diseases of the throat, and particularly in the practice of laryngoscopy. It is the nature, diagnosis, and treatment of diseases of the mucous membrane that is the division of the subject which constantly occupies the attention of all practitioners, and even when we limit our consideration to particular organs brings us into intimate relation with all others.

We could, in fact, with a little care classify most throat diseases under this title. At the same time it embraces a larger sphere; for the continuity of the gastro-pulmonary tract prevents our losing sight of a larger surface of this membrane, a point of great practical importance when we consider how often diseases of the throat extend to other parts. The lungs are peculiarly prone to suffer concomitantly, and it is chiefly the largeness of my subject that causes me to postpone for the present any gleanings respecting the bronchial division of the membrane. On the other hand the nose and mouth are quite as intimately connected with the throat, and as they receive less attention from most writers I shall venture to include a number of their diseases in my reports, more especially those originating in their mucous membranes.

In this branch of practice the introduction of the laryngoscope was an event the influence of which it would be difficult to exaggerate. What was before dark is now light. The most difficult problems have become clear as day. Looking back to the pre-laryngoscopic period is, therefore, like turning back to a comparatively dark age, and we shall only rarely have occasion to complete a subject by earlier citations, at least so far as laryngeal diseases are concerned.

Some of my readers are aware that my book on "Sore Throat" was the first English work in which the uses of the laryngoscope were shown. That book was written before Czermak's memoir had been translated, but it alluded to all the circumstances in which the instrument would probably be of use. After it appeared, Czermak visited England, and I had the pleasure of witnessing one of his auto-laryngoscopic demonstrations and of presenting him

with a copy of my work, in which he could observe how nearly he had been anticipated. In this book at least one case was related in which a mirror had been employed, not only for diagnosis, but for treatment—proving incontrovertibly that I was the first practitioner who used the laryngoscope for the purpose of aiding in the application of topical remedies. It may easily be understood that having, as it were, thus been a pioneer in the exploration and treatment of laryngeal diseases, I have never lost interest in the subject, and although, unfortunately, ill-health constrained me more than once to leave the sphere of my labours, since my re-establishment in London I have not ceased to devote much time and energy to the elucidation of these diseases, and, having accepted a post on the staff of the Hospital for Diseases of the Throat, I have abundant opportunities of practical work. I propose, therefore, to make my first report chiefly on laryngeal diseases, and, by way of introduction, to give some account of the laryngoscope and the art of using it—a brief sketch, in fact, that may serve the purpose of notes to the instruction I give at the hospital, and which I have often been asked by the pupils and visitors to publish.

I shall feel obliged to those of my professional brethren who have paid attention to the subject for any hints they may furnish, or for information as to the scope and intention of their writings, or the construction of instruments they have invented, it being my wish to faithfully describe the work of all who have advanced our knowledge of Diseases of the Throat.

Literature.

THE HALF-YEARLY ABSTRACT (a).

We might say almost the same of the Abstract as we have said of Braithwaite's Retrospect; it is a curiosity that two volumes should be so ably edited from the same material and yet resemble each other so little. Dr. W. Domett Stone succeeds well in carrying on the work which was planned and so long executed by Dr. Rankin.

We naturally judge most by our own pages with which we are but too familiar, and we find them well represented in the extracts made of the communications of Drs. Mapother, Tichborne, Corley, Swanzy, Luther, Prosser James, and others. The editor of the Abstract often places very interesting papers in the Appendix, and this time we find there Dr. Losterfer's paper on syphilis corpuscles and Professor Besiadecki's conclusions respecting them. As this subject has lately been brought prominently before our readers, we avail ourselves of this version for extract.

ART 1.—On the possibility of Diagnosing Syphilis by Means of Microscopical Examination of the Blood.
By Dr. LOSTORFER.

(*Medizinische Jahrbücher*, 1 Heft, 1871.)

"THE great mistrust with which, in almost all quarters, retailed observations on certain appearances in the blood in infectious diseases are received, induces me to commence this time with the results of my work hitherto obtained, and a statement of the manner in which I have shown that I can distinguish the blood of a syphilitic from the blood of a non-syphilitic individual."

"Prof. Stricker, who was kind enough to put my assertion to the proof, gave to me on several occasions a number of prepared blood tests, concerning the origin of which I was ignorant, some of these having been taken from healthy and others from syphilitic persons. They had been numbered and noted in

(a) "The Half-Yearly Abstract of the Medical Sciences." London: J. and A. Church

writing. After three, four, and at the most six days, I made him acquainted with the results of my examination; and then a comparison with the notes showed that—except in those instances where one or more preparations, either immediately after they were made or in the course of the examination, had been found useless, and so placed on one side—there was accordance between these notes and my results. Those tests which had been taken from healthy men I indicated as the blood of non-syphilitics, and those from syphilitic patients as the blood of such individuals.

"In a similar manner I have successfully carried out with success a test put by Prof. Hebra.

"The manner in which I have carried out my investigation is as follows: A drop of blood obtained by a puncture in the skin is transferred as rapidly as possible to a smooth slide, and covered by a thin protector. The blood test thus obtained is now placed in a bell-glass, arranged as a moist chamber, in which there is a stand for twelve preparations. In every glass of this kind I place the blood tests both of syphilitic and non-syphilitic individuals.

"The examination of these preparations is made daily with a N. 10 oc. 3, Hartnack's immersion lens.

"Whilst in general, during the first two days, nothing of a foreign nature was to be seen beyond some vibriones, bacteria, and sometimes the early forms of sarcena, on the third, many times on the fourth or fifth day, and exceptionally after the first twenty-four hours, I found small bright bodies, some of which were at rest and others presented vibratile movements. On some of these bodies a small process could be made out.

"On the fourth, exceptionally on the third, fifth, or sixth day, these bodies had become larger and increased in number. Many of the enlarged bodies presented the above-described process, which proved itself clearly to be due to a process of budding. In some, this had increased so much in size that it was almost as large as the maternal body.

"On the following days, the bodies increased more and more in size, so that some soon reached or even exceeded the size of shrivelled red blood-corpuscles. At the same time, however, smaller corpuscles were present in all gradations of size. Bud-formation also was now a frequently observed phenomenon, and many corpuscles had not only one outgrowth but several, which, some with and others without a stalk, were fixed to the maternal corpuscle. There were many instances in which one outgrowth was the bearer of secondary buds. Not all of these corpuscles were circular; many were irregular in form. After the specimen of blood had been kept for eight or ten days, a vacuole was formed in each of the larger corpuscles, which enlarged more and more, so that at last it was surrounded by only a thin membrane, indicated by a double contour. At this stage the development of the corpuscles had reached its end, and no further changes were observed, even in those cases—which, however, were very rare—where the blood remained suitable for examination at the end of a month.

"I proved also the conduct of the corpuscles on the addition of various fluids—such as solutions of sugar, distilled water, Pasteur's fluid, a solution of common salt, and a solution of acetic acid. These fluids, on the first day of their addition, had, notwithstanding their diversity, the same action. The corpuscles became shrivelled, and ran together into a quite irregularly-formed and opaque mass, and all further development was arrested. This change occurred with the greatest rapidity on addition of solution of sugar and of Pasteur's solution.

"At a later period, say about six or eight days after the appearance of these corpuscles, shrivelling occurred on the addition of one of the above-mentioned fluids, but by no means to such an extent as before. Many of the corpuscles appeared to be folded and had acquired an irregular form. Others retained their circular form, but were smaller, their contours were more distinct and their brightness not so well-marked. I have observed however a further development on the addition of distilled water, of an extremely diluted solution of sugar, and, in one case, of a solution of salt. In those instances the vacuoles enlarged rapidly, budding occurred, and there was also a formation of long extended processes which resembled very much the germ sacs of fungi.

"With regard to the quantity of the corpuscles in question; this varied very much: in some instances they were much scattered, in others they were very numerous. In one instance I counted on the fourth day, fifty in the field of the microscope. Whether the number of corpuscles has any relation to

the existing syphilitic symptoms remains to be determined by further investigation.

"The deviations from the above described modes of development consist chiefly in a more rapid or a slower development. In the first instance I found on the fourth day corpuscles which had attained almost the size of shrivelled blood-corpuscles. In cases of this kind, the corpuscles undergo the most manifold changes of form. The bud-formation was extremely unimportant. In later cases the corpuscles became distinctly perceptible for the first time on the fifth day; their growth was very slow, and when fully attained was rapidly followed by dissolution.

"Although I had first examined the blood of many healthy men without finding any of the above described corpuscles, I still persevered in the examination, and during a period of three months, I made use of simultaneously with specimens of blood from syphilitic subjects, specimens from healthy or at least non-syphilitic persons, and recently blood from patients affected with gonorrhœa, ulcers, and eczema. Generally the blood of syphilitic was kept in the same chamber with that of non-syphilitic persons. I have recently examined blood specimens of several patients suffering from typhus and lupus, and also one with elephantiasis græcorum.

"Now, since in no blood specimen from a non-syphilitic person, could I, notwithstanding the most careful examination, find any of the above described corpuscles, therefore must the possibility of finding these after several days' incubation in the blood of syphilitic persons, be regarded as somewhat characteristic of this disease. From this time I would give to those corpuscles the provisional name of syphilitic corpuscles.

"I have not yet carried on investigations at all times of the year, but have had occasion to remark that special attention ought to be paid to the temperature. Many of my researches were made at an indoor temperature fluctuating between 10° and 18° R., others in a place where the fluctuations of the temperature were still more considerable. In low temperatures I found that the results were negative."

Dr. Losterfer gives the details of thirteen cases of syphilis in which the blood of the patients presented the above described corpuscles.

Correspondence.

REPORTS ON FOODS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the interest of truth I feel impelled publicly to take exception to some of the teachings of your reporter on this subject.

In your issue of the 19th June, after showing that "Brown and Polson's Patent Corn Flour" contains 86 per cent. of starch and 9.2 per cent. of water, he adds, "it is decidedly a genuine article." Now, on the very face of it, this is a statement, that a preparation almost wholly composed of starch is a genuine "corn flour," which is substantially untrue. If your reporter had taken the trouble to make himself acquainted with Brown and Polson's process, he would have ascertained that it consists of means for obtaining common starch from maize by washing out the gluten, fat, &c. But this is not his only shortcoming. His statement implies that starch alone is a good article of diet. Such reckless utterances are most deplorable in a moral as well as in a scientific point of view.

The same deleterious twaddle is repeated in the reports on "Duryea's Prepared Maizena," and "Kingsford's Oswego Prepared Corn," both of which, like Brown and Polson's corn flour, are neither more nor less than common starch obtained from maize by a complicated system of washing.

On the other hand, hardly less pernicious are the statements put forward in the unfavourable report of June 26th on Du Barry's "Revalenta Arabica." It was surely enough to expose the impudent quackery of the greater part of that charlatan's assertions. Instead of confining himself to this legitimate work, your reporter has gone out of his way erroneously to depreciate the dietetic value of the lentil, which is the product whereof "Revalenta" is composed, and whose excellent properties are precisely that which renders it possible for the Du Barry imposture to be carried on successfully. He says, "the lentil is of food stuffs, one of

the most unpalatable, indigestible, and flatulent. Lentils are worth about twopence per pound, and are used on the Continent as a cheap food." The first part of this statement is utterly erroneous, as I can testify from having resided in a country where the lentil is the chief article of food of the working classes. When properly cooked it is palatable as well as digestible, and not particularly flatulent, except to those who are not in the habit of using it for food. The fact that "lentils are used on the Continent as a cheap food," instead of being a reason for warning the British public against eating them, is one for ascertaining and publishing their real dietetic value. But it is certain that the lentil, like many other varieties of pulse, is almost equal to butcher's meat as a flesh former. Experience, in countries where it is extensively used, proves it to be both nutritious and wholesome. It is moreover, very cheap. There is, consequently, nothing but vulgar prejudice, combined perhaps with culinary incapacity, to prevent the lentil being used with advantage by large numbers of people in this country. What an infinitely better food for children, for instance, would a savory "mess of pottage" of lentils eaten with bread be, than the usual British slops?

Cheap nutritious food is more than ever an acknowledged want. A wholesome nitrogenous article like lentils, costing no more than twopence per pound in the dry state, is evidently one well-fitted to supply that want; and as such is deserving to be commended by those who have the pretension to give lessons to the public on the subject of diet, instead of being rashly depreciated in accordance with the ignorant prejudices of our common people.

Yours obediently,

ERVA LENS.

* * In the "interest of truth," we must decline to endorse the remarks of "Erva Lens," which are certainly more energetic than discreet. The starches, when mixed with milk (it is in this form they are generally used), are invaluable as foods. The well-known arrow-root may be viewed as a type of this class of preparations. Bermuda arrow-root consists of 13 to 14 per cent. of moisture, the remainder being nearly chemically pure starch.

We made no such statement that starch alone is a good article of diet; but have already pointed out that foods which almost entirely consist of starch should be used with milk.

The writer of the above will have to bring forward more logical arguments before he persuades the public or the Medical Profession that lentils or peas are desirable foods for invalids or infants, because they are rich in vegetable casein. Lentil meal might be excellent food for a strong man leading a very active life, but we doubt if even the enthusiastic "Erva Lens" would recommend as a proper diet for a newly-born infant Dutch cheeses, because they contain so large a percentage of casein.

The flatulent and indigestible nature of the lentil or pea is so well recognised that we are surprised to find anyone has the temerity to dispute it. Yet the preparation that "Erva Lens" advocates is especially put forward for the use of invalids. The nutritive value (if digested) we did not express an opinion upon.

As regards the fact that lentils are largely consumed, as pointed out by ourselves, in other countries, it is no argument at all. In certain parts of the globe there are earth eaters, yet such a fact does not constitute earth containing a limited amount of organic matter, a desirable article of food for invalids and infants, or even for the hale and adults. An infinitely larger proportion of children die from over and improper feeding than from starvation.

A *propos* of casein and such like substances, we can lay our fingers on sundry analyses executed by good and efficient men in which the so-called flesh formers are calculated from the determination of the nitrogen by combustion. Can anything be more absurd as such a practice in estimating the value of a food, when some of the nitrogenous substances are contained in the portion of the cereals, which are perfectly incapable of assimilation, and simply pass through the

body mechanically and undigested? This, in our opinion, is "deleterious twaddle."

And now a word about the tone of "Erva Lens" letter. We think it "deplorable in a moral and scientific point of view," to find a writer of some slight ability allow his force of vituperation to exceed his common sense. In fact, the letter is a mass of assertions put in a most ribald style, and without the slightest point. We will tell him, however, what is our point. When manufacturers send out the starch of maize or any other grain carefully prepared, and when they make no secret of its composition or sources, and also sell it at a fair price (8d. per pound), such a preparation we consider good and genuine in every respect. But when a manufacturer sends out a substance that is retailed at the exorbitant rate of 5s. per pound, makes a secret of its composition, and denies that it is made from the grain of which it mainly consists, then, "in the interest of truth, we intend to speak out" in spite of the advocacy of such physiologists as "Erva Lens."

EDITORS OF THE FOOD REPORTS.

IS DISEASE IN THE SOLIDS OR IN THE FLUIDS?

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In my short and very imperfect article in your paper of the 15th of last May, I gave it as my opinion that disease was not in the solids but in the fluids—that is, in the blood. The soft solids are composed of arteries, veins, nerves, and lymphatics, and by this latter term I mean all those vessels which secrete and absorb, and as those form the whole animal economy, I will now endeavour to substantiate my opinion. The first disease I will examine is that which goes by the general name of "fever." The symptoms are all present and in full force, and I now ask, where is the disease? In the solids or in the fluids? Can it be in an artery or a nerve? I think not. What keeps up the heart's action? If it is not something in the blood, what is it? It is a plain question, where is the disease? It must be somewhere, and as the vessels are merely doing their duty, it is evident, I think, that it is in the blood. The artery pours out the blood, the vein takes it up, and the lymphatic absorbs the nutritive part which sustains the body, the disease cannot be in them, therefore the blood must be its seat. You want to lessen the heart's action first: How will you do it? What will your medicine act upon, the solids or the fluids? How can you act upon the heart unless through the blood?, with the pulse at 130 the blood is doing harm somewhere; now, if it is not doing the injury, what is it? The vessels? How can or could they do it? They are merely acting their part in the animal economy. When you give medicine it must act upon the blood, and if by so doing it removes the disease, does it not follow that the disease has been in the blood? if not, where has it been? in the arteries and veins, &c.?

What is the use in giving medicine if you do not know upon what it will act, and whether it will act or not? Let it act where it will, its first and direct action is on the blood. Ague is called an intermittent fever, yet it consists in a single paroxysm with three distinct stages: Where is the fever? What caused the paroxysm? Was it the solids? Where does the cause remain until the next attack? In the solids or fluids? Is it not evident that whatever the cause is, it is in the blood? You may remove the patient to another locality, but the cause goes with him. I do not see how a cause could lie in a solid, in an artery, or vein.

Cancer.—The parts were perfectly healthy until a small tumour the size of a pin's head was first felt; how did it come there? It is a deposit of some foreign matter from the blood, it becomes a foreign body and increases in size until ulceration takes place, or it may remain indurated. If the former, the healthy parts are rapidly absorbed, commonly called an "eating cancer." The matter secreted from the blood seems fatal to the surrounding parts, new vessels have been formed, and a new and peculiar action has taken place, because they secrete all this deleterious matter. What has occasioned all this? The blood, the foreign matter deposited by the artery from the blood, and refused to be taken up either by the vein or lymphatic; hence, the disease was in the blood. Why

cut it out? Because we possess no medicine powerful enough to alter the constitution of the blood in that locality. When this matter is deposited in a gland and runs along the lymphatics from gland to gland, the case is hopeless; we have no power over the blood.

Gout.—In this case it appears to me that the blood runs to the joints to cause it—upon the same principle as it runs to the liver—to secrete bile; it acts upon certain parts and nowhere else. I have suffered from it for forty years. It is strange that gout only attacks half of the joint, the upper or outer part; now, for instance, the back of my hand from the wrist to the end of the fingers have only been attacked, the palm of my hand and the inside of the fingers have been perfectly free from it; and the same has been the case with both great toes and feet, the upper or outer vessels are the only ones engaged, and they have been injected with blood to the utmost extension possible; then a relaxation took place until it entirely subsided, absorption going on but slowly, though surely. Nothing can prevent the rush of blood; when it begins it will have its way, and nothing can relieve the pain except opium. You cannot cure gout, because you cannot prevent the rush of blood, it is utterly impossible. Where is the cause? Is it in the vessels of the part or in the blood? I have watched my hand from the first twinge until it was swollen fully one inch, then it stopped, and the pain was only terrible, from pressure on the nerves, which was only relieved by opium deadening the sensibility; the middle joint of both little fingers were engaged, but only the upper half. I could rub the under parts with impunity. Why is this one circle of vessels only engaged? It cannot be the fault of the vessels, the cause must lie in the blood; but why attack a particular part? I might as well ask why bile, urine, and gastric juice are secreted from the same blood. Take inflammation of any kind, and say that the engorgement of the arteries depends upon the arteries themselves. What causes a dry hot skin, and why do not the lymphatics pour out their usual fluid? Is it in the blood to pour out? The tongue and mouth are dry and parched, and the stomach calls out for fluid. May not the latter be as dry as the former? Why will the vessels not secrete? Is there anything to secrete? Is not the blood in some disorganised state? If not, what is wrong and where? If you cannot find the cause of disease in the blood, where will you look for it? In an artery, vein, nerve, or lymphatic? These compose the solids. Take any disease you like and trace it to its source, and you will find the "casus belli" in the blood and nowhere else. If the stomach will not absorb any of the medicine you put into it, of what use is the medicine? And if it is absorbed, is it not thrown first into the blood, and is not its chief action upon it? What do your diuretics and diaphoretics act upon, if they do not act upon and prepare the blood for its proper use? Even suppose that they act upon the vessels—the solids—it must be through the blood. If the blood is pure, you have no disease; hence, it must be that there is a something in the blood, a something which entered it, "*ab externo*," that causes disease. There are diseases induced by debility of, as well as poisonous miasma in, the blood, and there is a distinction between diseases and maladies, but of these hereafter.

I remain, Sir,

Your obedient servant,

ALEXANDER LANE, M.D., R.N.

Ludlow, Salop, July 4, 1872.

P.S.—I had thought that the authorities engaged in drawing up our new nomenclature would have paid some attention to the names of diseases, and made some analogy between the name of the disease and the disease itself; but they did not, and went on in the old beaten track. To wit "hydrophobia"; a fear of water is no disease, besides, it is wrong; a mad dog bites a man, the poison is absorbed, thrown into the blood, and attacks the brain, and the disease is called a "fear of water." Again, "sunstroke." There is no such disease; the sun cannot strike a man, intense heat may cause a rush of blood to the brain which the veins cannot return quick enough, and thus cause "congestion," and this is in reality the disease. Again, "phlegmasia dolens." I never saw inflammation here in any case that came under my observation, it appeared to me to be obstruction in the lymphatic system. Is the English language so poor that it cannot give a name to a disease, but we must look to the dead languages for one, Greek or Latin.

WHAT CONSTITUTES A DR. ?

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having for some time noticed several letters in the MEDICAL PRESS and *The Doctor* on the subject of the right of men to sign M.D. after their names, they not possessing a degree from a British University, I think it would be well to state the wording of the Medical Act on the subject. It says, at Section 40, "That any person who shall wilfully and falsely pretend to be or take or use the title of Physician, Doctor of Medicine, or any title, name, addition, or description implying that he is recognised by law as a physician, shall, upon summary conviction, pay a sum not exceeding £20." This is to my mind a very clear legal qualification for any registered physician to sign himself by any name, title, addition, or description that he may think proper to show that he is a physician and recognised by law as such. If this view is wrong, then a M.D., although he may be registered and recognised by law as such, has no right or title to call himself a physician, unless he holds a diploma from one of the Colleges of Physicians authorised by law to grant the same. In conclusion, I think it only right to say that Mr. Chandler not only deserves the thanks, but the support of the whole Profession.

I am, Sir,

Your obedient servant,

WILLIAM DONOVAN, L.R.C.P.Ed., &c.

Adare, July 4th.

Gleanings.

Elixirs and Wines.

(Continued.)

Elixir of Pyrophosphate of Iron, Quinia, and Strychnia requires particular manipulation, which precludes the use of simple elixir. The following formula—the result of concert of experiments of my friend Mr. E. Scheffer and myself—has been used by me since autumn, 1869, and I can recommend it as uniformly successful when the manipulation is carefully conducted:—

Take Sulphate of quinia	60 gr.
Strychnia	1 gr.
Citric acid	5 gr.
Stronger alcohol	f ʒij.
Solution of oil of orange	℥ i.
Syrup	f ʒ vj.
Pyrophosphate of iron	ʒss.
Distilled water	f ʒvij.
Aqua ammonia	q. s.

Triturate the sulphate of quinia, strychnia and citric acid together until minutely divided, then add the alcohol and solution of oil of orange. Warm the syrup slightly (to about 150° F.), and add to the turbid alcoholic mixture; when, upon stirring, the mixture becomes clear. To this add the pyrophosphate of iron, previously dissolved in the distilled water, and finally aqua ammonia carefully (drop by drop), until the elixir is perfectly neutral to testpaper; filter.

The finished preparation has a greenish yellow colour, a pleasant flavour of orange, and is permanent.

Elixir of Calisaya Bark with Iron.

Take of pyrophosphate of iron 128 grains, soften in two fluid drachms of water, and stir in gradually 1 pint of Elixir of Calisaya Bark; filter.

Elixir of Calisaya Bark with Iron and Strychnia.

Dissolve 1 grain of strychnia and 1 grain of citric acid in two fluid ounces of water, add 1 pint of elixir of Calisaya bark with iron, mix and filter.

Elixir of Calisaya Bark with Iron and Bismuth.

Dissolve 128 grains of pyrophosphate of iron and 128 grains of ammonio-citrate of bismuth in 2 fluid ounces of distilled water, add 14 fluid ounces of elixir of Calisaya bark; mix and filter.

Elixir of Calisaya Bark with Iron, Bismuth, and Strychnia.

Dissolve 1 grain of sulphate of strychnia in 2 fluid drachms of water, add 1 pint of elixir of Calisaya bark with iron and bismuth; mix and filter.

Elixir of Calisaya Bark with Iron and Beef.

Dissolve half an ounce of extract of beef (prepared by Liebig's method) in 1 pint of elixir of Calisaya bark with iron; allow it to stand several days (if possible), and filter.

Elixir of Pyrophosphate of Iron.

Soften 256 grains of pyrophosphate of iron in half fluid ounce of water, add 15½ fluid ounces of simple elixir; mix and filter.

Elixir of Bismuth.

Dissolve 256 grains of ammonio-citrate of bismuth in 4 fluid ounces of distilled water, mix with 12 fluid ounces of simple elixir, and filter.

Elixir of Valerianate of Ammonia.

Dissolve 256 grains of valerianate of ammonia in 2 fluid ounces of simple elixir, carefully add aqua ammoniac until the solution is exactly neutralised; then mix with 14 fluid ounces of simple elixir; filter and colour with cochineal colour to a bright red.

Elixir of Valerianate of Ammonia and Quinia.

Triturate 64 grains of valerianate of quinia until minutely divided, then dissolve in it 1 pint of elixir of valerianate of ammonia, and filter.

Elixir of Valerianate of Ammonia, Quinia, and Strychnia.

Dissolve 2 grains of strychnia in 2 fluid ounces of water, by the aid of just sufficient valerianic acid; mix with 1 pint of elixir of valerianate of ammonia and quinia, and filter.

Elixir of Valerianate of Quinia.

Triturate 128 grains of the valerianate of quinia until minutely divided, mix with 1 pint of simple elixir, carefully add valerianic acid until the liquid becomes clear, shaking after each addition, and filter.

Elixir of Valerianate of Quinia and Strychnia.

Dissolve 2 grains of strychnia, minutely divided, in 2 fluid ounces of water by the aid of just sufficient valerianic acid; mix with 1 pint of elixir of valerianate of quinia, and filter.

Elixir of Valerianate of Strychnia.

Dissolve 3 grains of strychnia in 2 fluid ounces of water by the aid of just sufficient valerianic acid; mix with 1 pint of simple elixir, and filter.

Elixir of Bromide of Potassium.

Dissolve 1 ounce of bromide of potassium and 1 ounce of sugar in 1 pint of simple elixir; add 20 minims of solution of oil of orange and 10 minims of solution of oil of bitter almonds, and filter. Colour with cochineal colour.

Elixir of Bromide of Sodium.

Prepare this like elixir of bromide of potassium, substituting bromide of sodium for bromide of potassium, and omitting the colour.

Elixir of Bromide of Ammonium.

Prepare this like elixir of bromide of potassium, substituting bromide of ammonium for bromide of potassium, and omitting the colour.

Elixir of Hops.

Add 2½ fluid ounces of fluid extract of hops—made according to formula for F. E. Gentian, U.S.—to 13½ ounces fluid ounces of simple elixir; mix and filter.

Elixir of Lupulin.

Triturate 2 ounces of fluid extract of lupulin with 2 ounces of carbonate of magnesia, add 14 fluid ounces of simple elixir; transfer to a bottle, agitate occasionally for several hours, and filter.

Elixir of Gentian and Pyrophosphate of Iron.

Triturate 100 minims of solution of oil of orange with 2 ounces of sugar; dissolve it in 8 fluid ounces of elixir of pyrophosphate of iron and 6 ounces of simple elixir, add half ounce alcohol and half a fluid ounce of fluid extract of gentian; mix and filter.

Elixir of Chloral Hydrate (a).

Dissolve 2 ounces of chloral hydrate in 1 pint of simple elixir, and filter.

Wine of Iron.

Dissolve 128 grains of ammonio-citrate of iron in 2 fluid ounces of water, add 1 pint of wine of orange; mix and filter.

Bitter Wine of Iron.

Dissolve 128 grains of soluble citrate of iron and quinia in 2 fluid ounces of water, add 1 pint of wine of orange; mix and filter.

Wine of Wild-cherry Bark.

Mix 1 ounce of fluid extract of wild-cherry bark, 2 fluid ounces of syrup of wild-cherry bark, 10 minims of solution of oil of bitter almonds, and 13 fluid ounces of wine of orange. Allow to stand several days, and filter.

Wine of Wild-cherry Bark and Pyrophosphate of Iron.

Soften 128 grains of pyrophosphate of iron in 2 fluid drachms of water; add 1 pint of wine of wild-cherry bark, mix and filter.

Wine of Beef.

Dissolve half an ounce of extract of beef (Liebig's method) in 1 pint of wine of orange, and filter.

Wine of Beef and Iron.

Dissolve half an ounce of extract of beef (Liebig's method) in one pint of wine of iron, and filter.—*Pharmacist.*

Medical News.

Royal College of Surgeons of England.—The annual meeting of the council for the election of the president and vice-presidents, the several professors and examiners in medicine and midwifery, was held last Thursday, when Henry Hancock Esq., of Harley Street, was elected president in the room of George Busk, Esq., F.R.S., and T. B. Curling, Esq., F.R.S., and F. Le Gros Clark, Esq., F.R.S., vice-presidents of the college for the ensuing year. Dr. Thomas B. Peacock, physician to St. Thomas's Hospital, and Dr. Wilks, F.R.S., physician to Guy's Hospital, were elected examiners in medicine; Dr. Arthur Farre, F.R.S., Dr. Robert Barnes, and Dr. Priestley, were elected examiners in midwifery; William Henry Flower, Esq., F.R.S., was elected professor of comparative anatomy; Erasmus Wilson, F.R.S., professor of dermatology; T. Holmes, Esq., F.R.C.S., professor of anatomy and surgery, and Dr. Humphry, F.R.S., of Cambridge, professor of anatomy and physiology.

Apothecaries' Hall of England.—At a Court of Examiners held on the 11th instant, the following gentlemen, having passed the necessary examinations, received the L.S.A. diploma, viz.:—Messrs. Oliver Barber, of Sheffield; J. L. W. Forder, of Mauritius; Robert Bruce Low, of Edinburgh; Frank Reid, of London; Francis Leigh Riley, of Sydney, New South Wales; and Alfred Milward Sculthorpe, of Tamworth. And the following passed the primary professional examination, viz.:—Messrs. Samuel Bingham, of Guy's Hospital; Richard Jelley, of University College; William V. Lindsay, of St. Mary's Hospital; Rees Ralph Llewellyn, of the London Hospital; and Russell Main Talbot, of Guy's Hospital.

The Danger from Infectious Diseases.—In the case of *Best v. Stap*, heard in the Court of Queen's Bench, an important question as to the liability of taking about persons suffering from infectious disease so as to endanger the health of others, has been raised. The plaintiff is a lodginghouse keeper at Eastbourne. The defendant is a gentleman residing near London. The action was brought to recover damages for the losses the plaintiff had sustained by the death of his children and illness of his wife, and from being

(a) This elixir was first prepared by me at the request of a gentleman who habitually used the chloral hydrate, and he finds that the chloral dissolved in this way retains its virtues most completely during the period required for the consumption of one quart. For this reason I have given the formula for its preparation, thinking that if such a preparation is desirable this seems to serve the purpose.

prevented from letting his lodgings, in consequence of the defendant having brought his family into the plaintiff's house when they were suffering from scarlet fever. The evidence for the plaintiff was given by his wife, Mrs. Best, who said that in August, 1870, arrangements were made by the defendant's wife to take rooms in her (Mrs. Best's) house, and ultimately, on September 1, Mrs. Stap, the defendant's wife, came with her family, governess, and nurse. The plaintiff had four children living in his house. Mrs. Stap brought five with her. Mrs. Best was engaged when they came, and did not see them, but she was told that Mrs. Stap's little boy was ill from a cold, and he was put in bed. In a few days Mrs. Best spoke to Mrs. Stap in consequence of it having been suggested to her by her other lodgers that something more than a cold was the matter with the children, but she was assured by Mrs. Stap that this was not so. Mrs. Best also advised a doctor being called, but this was declined. On the 10th of September a doctor was called in to attend Mrs. Stap's daughter, who also was taken ill, and she was found to be suffering from scarlet fever. The doctor told Mrs. Best this, but up to this time she had not known or heard anything about scarlet fever having been the illness from which Mrs. Stap's family were suffering. On the 12th of September Mrs. Best's child was taken ill. Shortly after that one of Mrs. Stap's children died, and on the 29th Mrs. Best's child died. On the 1st of October another of Mrs. Stap's children died and on the 16th another of Mrs. Best's. After the death of her first child Mrs. Stap went to London and never returned. Her family were not allowed to leave for some time by the officer of health, as they were not in a fit state to travel. The plaintiff's wife said that nothing at all was told her previously to Mrs. Stap coming to her house about the children suffering from scarlet fever, and evidence was given that Mrs. Stap had endeavoured to conceal the fact from Mrs. Best, and also that they were absolutely affected with it when they went down to Eastbourne, and that Mrs. Stap knew it. At the conclusion of the plaintiff's case, Mr. Field, on behalf of the defendant, submitted that there was no evidence against the defendant personally, and that the wife was not the agent of her husband to make the alleged false representations.—Mr. Justice Quain ruled that if the wife knew of the children being ill from scarlet fever at the time she took them to the plaintiff's house, there would be a verdict for the plaintiff, as the wife must be taken to be the agent of her husband, the defendant. The evidence for the defence was, that one of the children had suffered from scarlet fever, but had recovered, and that the doctor told Mrs. Stap that they might be removed, as they were out of danger.—Mrs. Stap also denied having concealed the fact of the children having the fever from Mrs. Best. Ultimately the jury returned a verdict for the plaintiff, damages £120.

Opium Eating.—The Legislature of Kentucky, in order to check the practice of opium eating, which is greatly on the increase, has just passed a bill that on the affidavit of two respectable citizens, any person who, through the excessive use of opium, arsenic, hasheesh, or any drug, has become incompetent to manage himself or his estate, may be confined in any asylum and placed under guardianship, as in the case of habitual drunkards or lunatics.—*Med. and Surg. Reporter.*

NOTICES TO CORRESPONDENTS.

Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this request.

All communications intended for insertion, must bear the name and address of the writer; not necessarily for publication, but as a voucher of good faith.

Rejected MS. will always be returned, if a request be received from the author, within one week after the article or letter has been declined.

Subscriptions in the United States.—A Correspondent has drawn our attention to the fact, that some of the houses in the United States are charging the enormous figure of 15 dollars per annum (more than £3) for supplying this Journal to different parts of the States. We beg, therefore, to state that we shall be happy to supply the same

regularly post free per annum, if paid in advance, for considerably less than half this amount, viz., six and-a-half dollars (about £1 6s. 0d.), either direct from our offices in this country, or through our recognised agents in the United States.

To our Subscribers.—It having been suggested to us that it would be a matter of great convenience to Subscribers visiting the metropolis to know where they can give instructions for their letters to be addressed previous to leaving home, we have pleasure in informing them that the Publisher has consented to take charge of letters addressed to his care, and that he will place a desk at the disposal of Subscribers whose names are upon our lists, for short correspondence, where such accommodation is desired.

Reports on Foods.—A Correspondent writes: "I was much pleased with the exposure by the analysis of Barry Du Barry's Revalenta in your columns. This stuff has for years past appeared in almost every newspaper at home and abroad, and is, to my mind, further proof of how the fools will support the knaves. If such patent (?) is to be allowed and protected by Government stamps, its composition should be correctly stated, and if altered so as to be injurious to the health of the people, its proprietor should be visited with a heavy fine. The Profession is much indebted to the MEDICAL PRESS AND CIRCULAR for its fearless exposure of every kind of quackery." We thank our Correspondent.

The Bastardy Laws.—In the House of Commons on Friday last, an honourable member moved that 5s. per week should be the maximum fine for the maintenance and education of illegitimate children, instead of 2s. 6d. as at present. The proposition was defeated on a division.

L. A. R.—The publication is a very small one, but contains some really good matter, and will be found very interesting, especially to one interested in the treatment of the insane. The publishers' names were given in our last.

Swiss Milk.—The *Swiss Times* says that at the condensed milk manufactory in Cham there are 10,000 quarts of milk condensed every day, and as many more in the branch establishments at Gossau (Canton St. Gall) and Düringen (Canton Friburg) taken together. Four-fifths of this condensed milk goes to London.

A Sufferer.—We make a point of never recommending one practitioner in preference to another. The fact of your having consulted "a qualified Medical man" in your town without deriving benefit is no argument that you should leave him for another. The fault may be, and probably is, entirely your own, as the malady of which you complain is so simple, and of such an every day occurrence, that the merest tyro in medicine would readily prescribe an effectual remedy. We commonly hear of cases in which the real cause of your particular illness is sedulously kept from the family Medical attendant for fear that "he will reveal the secret." If this be so with you, you little imagine how you libel the Profession, and prolong your own suffering.

Dr. Francis Hogg, Woolwich.—We will look up the names of a few authorities on the subject, and send you a private note. Your communication is interesting, and the case of rare occurrence.

VACANCIES.

Board of Police, Glasgow. Sanitary Medical Officer, at a salary of £6 0 per annum. (See advt.)
 Manchester General Hospital for Sick Children. Medical Officer. Salary £100 per annum, with board and residence. (See advt.)

APPOINTMENTS.

DOBSON, N. C., Lecturer on Anatomy at the Bristol Medical School.
FRENCH, E. T., L.R.C.S.I., Medical Officer, &c., for the Glasson D's dispensary District of the Athlone Union, Co. Westmeath.
GRIFFITH, R. G., M.R.C.S., House-Surgeon to the Carnarvon Infirmary.
JONES, M., L.R.C.P., Medical Officer for the Aberystwith Union Work-house.
LATHAM, W. H., M.R.C.S.E., House-Surgeon to the Salford and Pendleton Royal Hospital and Dispensary, Manchester.
LOWNDES, F. W., M.R.C.S.E., Medical Officer for District No. 12 of the Parish of Liverpool.
M'SWENEY, M. O' C., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer, &c., for the Oulart Dispensary District of the Ennis-corthy Union, and Medical Officer to the Fever Infirmary.
MORRIS, J. H., M.R.C.S.E., District Surgeon to the Salford and Pendleton Royal Hospital and Dispensary, Manchester.
PARKS, Dr. W. J., Medical Officer, &c., for the Ely Dispensary District of the Enniskillen Union, Co. Fermanagh.
PIKE, W. R., M.R.C.S.E., Medical Officer for Out-patients of the Royal Portsmouth, Portsea, and Gosport Hospital.
SMITH, A. M.D., F.K.Q.C.P.I., Treasurer to the King and Queen's College of Physicians in Ireland.
FRENCH, W. H., Lecturer on Physiology at the Bristol Medical School.
STOREY, J. A., L.R.C.S.I., House Surgeon, *pro tem.*, to the North Riding Infirmary, Middlesborough-on-Tees.
WOODS, B. A. H., M.R.C.S.E., Medical Officer for District No. 6 of the Parish of Liverpool.
WISE, G., M.D., Hon. Secretary to the Apothecaries' Benevolent Fund, Ireland.

Marriages.

EWART-KANE.—On the 4th of July, at St. Mary's, Islington, John Henry Ewart, L.R.C.P.L., of Cheetham Hill, Manchester, to Emily Matilda Christine, daughter of Matthew Kane, M.D., Deputy Inspector-General of Hospitals H.M.'s Madras Army, of Dinan, France.
REW-COKE.—On the 4th of July, at Christ Church, Luton, James Rew, Esq., M.R.C.S., of Luton, to Margaret, youngest daughter of the late R. Cooke, Esq., of Stamford, Lincolnshire.
TAYLOR-CURRIE.—On the 4th of July, at the Parish Church, Glyn Ceiriog, near Llangollen, Jas. Taylor, L.R.C.P.L., of Chester, to Annie, daughter of the late Robert Currie, Esq., of London.
WILLS-HOLMES.—On the 3rd of July, at St. Peter's Church, Dublin, C. S. Wills, Staff Assistant-Surgeon, to Louisa Lucy, second daughter of the late Rev. James P. Holmes, Rector of Gallen, King's County.

Deaths.

ALLAN.—On the 6th of July, at Grafton Terrace, North John Street, Glasgow, J. Allan, M.B., L.R.C.S.Ed., L.M.
BRADLEY.—On the 3rd of July, J. K. Bradley, L.K.Q.C.P.I., L.R.C.S.I., of Kilmoganny, Co. Kilkenny, aged 27.
COULTER.—On the 3rd of July, at Penally, near Tenby, South Wales, of pneumonia, John R. K. Coulter, M.B., L.R.C.S.E., Staff Assistant-Surgeon Army Medical Department, aged 31.
COLCHESTER.—On the 29th of June, T. Colchester, M.R.C.S.E., of Bushy Heath, Herts, late Surgeon Royal Artillery, aged 70.
EVEREST.—On the 28th of June, at Mayland Road, Shepherd's Bush, George James Everest, M.D., aged 77.
FITZPATRICK.—On the 1st of July (after a short illness), at Lenham, Kent, John Fitzpatrick, M.D., Surgeon-Major H.M.'s Ind. an Army (retired), aged 54.
SMITH.—On the 20th of June, J. G. Smith, M.D., of Union Terrace, Aberdeen, aged 45.
SUFFIELD.—On the 23rd of June, Wm. H. Suffield, M.D., of Letter-track, co. Galway, aged 66.

ST. THOMAS'S HOSPITAL, ALBERT EMBANKMENT, WESTMINSTER BRIDGE, S.E.—THE MEDICAL SESSION for 1872 and 1873, will commence on TUESDAY, the 1st OCTOBER, 1872, on which occasion an INAUGURAL ADDRESS will be delivered by Mr. CAWST, at Two o'clock.

GENTLEMEN entering have the option of paying £40 for the first year, a similar sum for the second, £20 for the third, and £10 for each succeeding year; or, by paying £105 at once, of becoming perpetual Students.

PRIZES & APPOINTMENTS FOR THE SESSION.

THE Wm. TITE SCHOLARSHIP, founded by Sir Wm. Tite, C.B., M.P. F.R.S., the proceeds of £1,000 Consols, tenable for three years, will be awarded at the end of the Winter Session.

First Year's Students: WINTER PRIZES—£20, £15, and £10. SUMMER PRIZES—£15, £10, and £5.

Second Year's Students: WINTER PRIZES—£20, £15, and £10. SUMMER PRIZES—£15, £10, &c. The DRESSERSHIP, and the CLINICAL and OBTURIC CLERKSHIP.

Third Year's Students: WINTER PRIZES—£20, £15, and £10. Mr. GEORGE VAUGHAN'S CHESEBOLD MEDAL. THE TREASURER'S GOLD MEDAL. THE GRAISNER TESTIMONIAL PRIZE. THE TWO HOUSE PHYSICIANSHIP. THE TWO HOUSE SURGEONSHIP. THE RESIDENT ACCOUCHERSHIP. TWO MEDICAL REGISTRARSHIPS, at a Salary of £40 each, are awarded to 3rd and 4th year's Students, according to merit.

MEDICAL OFFICERS.

HONORARY CONSULTING PHYSICIANS—Dr. Barker and Dr. J. Bisdon Bennett.

Dr. Peacock, Dr. Britow, Dr. Clapton, Dr. Murchison, Dr. Barnes, Mr. Le Gros Clark, Mr. Simon, Mr. Sidney Jones, Mr. Croft, Mr. Liebreich, Dr. Stone, Dr. John Harley, Dr. Payne, Dr. Gervis, Mr. MacCormac, Mr. Francis Mason, Mr. Hy. Arnott, Mr. J. W. Elliott, Dr. Evans, Mr. W. W. Waststaffe, Mr. E. W. Jones.

MEDICINE.—Dr. Peacock and Dr. Murchison. SURGERY.—Mr. Le Gros Clark and Mr. Sydney Jones. GENERAL PATHOLOGY.—Dr. Britow. PHYSIOLOGY and PRACTICAL PHYSIOLOGY.—Dr. Ord and Dr. John Harley. DESCRIPTIVE ANATOMY.—Mr. Francis Mason and Mr. W. W. Waststaffe. ANATOMY in the dissecting room.—Anatomical Lectures—Mr. Rainey, and Mr. Wm. Anderson. PRACTICAL and MANIPULATIVE SURGERY.—Mr. Croft and Mr. MacCormac. CHEMISTRY and PRACTICAL CHEMISTRY.—Dr. A. J. Bernays. MIDWIFERY.—Dr. Barnes. PHYSICS and NATURAL PHILOSOPHY.—Dr. Stone. MATERIA MEDICA.—Dr. Clapton. FORENSIC MEDICINE and HYGIENE.—Dr. Stone and Dr. Gervis. COMPARATIVE ANATOMY.—Mr. C. St. John. OPHTHALMIC SURGERY.—Mr. Liebreich. BOTANY.—Rev. Wale Hicks, M.D. DENTAL SURGERY.—Mr. J. W. Elliott. DEMONSTRATIONS MORBID ANATOMY.—Dr. Payne. MENTAL DISEASES.—Dr. Wm. Rhys Williams. GEOGRAPHICAL DISTRIBUTION OF DISEASES in ENGLAND and WALES.—Mr. A. Haviland. B. G. WHITFIELD, Medical Secretary.

T. D. PEACOCK, M.D., DEAN.

For entrance or Prospectuses, and for information relating to Prizes and all other matters, apply to Mr. WHITFIELD, Medical Secretary, St. Thomas's Hospital, S.E.

THE ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road (Founded A.D., 1814)

NOTICE IS HEREBY GIVEN, that the Council will meet in the Board Room of the Hospital on TUESDAY, the 6th day of August, 1872, at Four o'clock in the afternoon, to receive and examine applications from Candidates for the office of PHYSICIAN to the Hospital, vice Dr. J. C. Fish resigned.

The qualification required according to Law XIII is, that the Candidate must be registered as a Fellow or Member of the Royal College of Physicians of England, and not practising Midwifery or Pharmacy. Any further information may be obtained on application personally or by letter to the Secretary or Resident Medical Officer.

Letters of application with testimonials to be sent to the Hospital addressed to the Secretary on or before 12 o'clock at noon, on Tuesday, August 6th.

The Election will take place at a Special General Court of Governors, to be held on Monday, August 26th. Governors may vote by proxy.

By order, C. LOWTHER KEMP, Secretary to the Council, &c.

INDIAN MEDICAL SERVICE.

NOTICE IS HEREBY GIVEN, that an Examination of CANDIDATES for fifteen appointments as ASSISTANT SURGEONS in her Majesty's Indian Medical Service will be held in London, on MONDAY, the 12th August, 1872, and following days.

Copies of the regulations for the examination of Candidates, together with information regarding the pay and retiring allowances of Indian Medical Officers, may be obtained on application at the Military Department, Westminster, London, S.W.

T. T. PEARS, Major General, India Office, 2nd July, 1872. Military Secretary.

GENERAL HOSPITAL and DISPENSARY for SICK CHILDREN, 18 Bridge Street, Manchester.—A VACANCY having occurred in the office of Resident Medical Officer, through the illness of the present holder of it, Candidates are required to send in their APPLICATION and TESTIMONIALS on or before July 22nd. Candidates must be unmarried and their names must be on the Medical Register. Salary £100 per annum with residence and board.

PRACTICE FOR SALE.—A very moderate figure will be taken for Introduction. £800 a year can be realised easily. Situate in one of the most fashionable watering places in Devonshire. House and furniture can be had by arrangement, if desired. None but a thoroughly qualified Medical man need apply. L. S. M., London Office of this paper, 20 King William Street, Strand.

THE ARMY SURGEON, HIS WORK AND WORKS (a).

By C. A. GORDON, M.D., C.B., Dep. Insp.-Gen. of Army Hospitals.

(Continued from page 41.)

WITHOUT those reinforcements that day must have been lost to our arms. As a contrast, permit me to remind you of Walcheren. You all know the history of our expedition to that island in 1809. The causes of disease were rife. Sir James M'Grigor and Sir William Burnett, the Medical heads of the land and naval forces, jointly drew up a code of hygienic rules, equal, it may be observed, to any of the more modern and scientific. Those instructions, however, found no favour in the eyes of the commanders. They were consequently unapplied. The expedition came absolutely to nought. The following year, a parliamentary investigation into the miscarriage took place; and in the proceedings of that Commission you may still read that, in the opinion of the commissioners, had the instructions of the Medical officers been followed, thousands of lives and tens of thousands of pounds sterling would have been saved to England. Perhaps in our day the hygienic recommendations of responsible authorities dared not be ignored by commanders as they were in the days to which we have just referred. The present very advanced state of public opinion would doubtless check the evil in its bud, or, at any rate, before its full development; nevertheless, have we not as a body the right to ask whether, our functions having, as I have just pointed out, so enormous an influence upon the efficiency and consequent success of armies, we are not justly entitled to receive a measure of consideration proportioned to the importance of the services we perform?

(a) Presidential Address delivered at the St. Andrew's Graduates' Association, on Saturday, July 6th, 1872.

Unhappily for ourselves, we for the present occupy a sort of no-man's land. When public recognition of civil Medical services is on the tapis, we learn in a very marked manner that we are in the army. When for military services before an enemy, we are reminded that we are "doctors." It has not been so always; neither will it be. There was a time when military commanders and authors wrote of army surgeons in terms which the poet transposes:—

"A wise physician skilled our wounds to heal,
Is more than thousands to the public weal."

History repeats itself. The time has come when the services rendered by army surgeons more than ever merit the delicate paraphrase of Pope.

May I be permitted to allude very briefly to some of the ameliorations in the condition of the soldier, mainly or altogether due to the Medical officers of the army.

It is not so long ago since the sleeping places of our soldiers consisted of a series of shelves, arranged in double tiers along the sides of their barrack room, like bunks on board an emigrant ship of the olden time. On each such shelf, two, and, in emergencies, three men lay side by side; the recruit just joined, filthy and often diseased as he was, was accommodated in the first berth that happened to be vacant; when a soldier went on guard, his place was taken by the next who happened to need a bed; and he on his return from his turn of duty was similarly disposed of. Truly, the soldier of those days had many strange bedfellows; nor were they of his own seeking.

Need we wonder that typhus and eruptive fevers were rampant in the army, and cutaneous affections all but universal among the soldiers? This system, injurious alike to the physique and morale of the soldier, was abandoned in consequence of the loud and long-continued protests of the army surgeons; and the paragraph in their regulations, as those stood prior to 1859, now reads strangely—that every man should have a separate bed. Will you believe it? what has long since been banished from the army still lingers in the militia—one *billet* is even now taken for two militia men! Means of personal

ablution were, perhaps, upon a par with the sleeping accommodation, so much so that satirical writers were wont to describe the process by which the British grenadier performed his morning toilet—taking a mouthful of water, then squirting it into his hands, he thus washed his face. How he dried his manly countenance is not recorded in history; but as to his dandruff-covered person, his gorgeous uniform compensated for and concealed all that. See now the ablution and the bath rooms erected in every barrack for the soldier. Recollect that while all that has been effected in both respects, has been so on the urgent recommendation of army surgeons, very much more would have been done, in these and other respects, had more than a tithe of their recommendations been carried out.

In regard to food, the abolition of the old system whereby soldiers on foreign stations were restricted to salted provisions almost completely as if they were on board ship, was abrogated after years of protest on the part of army surgeons; and good as the present fresh ration is, it would have been still better had full scope been given to their recommendations. As regards appropriate diet for the sick, even so lately as the end of last century a soldier while under Medical treatment, let us say on account of dysentery or yellow fever in the West Indies, received, as diet and support, his regular ration of salted pork and rum, for in those days spirit drinking was compulsory on his part. Our present improved system is due to the representations of army surgeons, some of whom, notably Dr. Robert Jackson, had introduced suitable scales of diet into their hospitals before the system was sanctioned by regulations. It was an army surgeon—namely, Dr. Hamilton—who first protested against the extent to which, in bygone days, the barbarous and degrading punishment of the lash was carried in the army. He did even more than this. He pointed out that many offences are committed by soldiers from sheer ignorance of the code of laws under which they serve, and condemned the nomenclature according to which crimes and offences are enumerated in establishing what is called a *regimental* character; offences merely against military usages and rules being to a certain extent placed upon the same footing as those against person or property.

With reference to other matters of general hygiene, we need but refer to the works of such men as Pringle, Monro, Jackson, Bell, and Ballingall, to read in their pages the very principles in regard to barrack and hospital construction, the proper size of rooms, and appropriate sites for these buildings, which we find of late years paraded, with all the aspect of originality, in works by so-called sanitary reformers; the opinions, if not the very words, of the army surgeons being given, but not a syllable as to the source from whence the plagiarism had been made. I have indicated the principal old army writers, so that you have it in your own power to test the correctness of my statement, and prove for yourselves whether or not the labours of my military brethren have received in these respects the recognition justly due to them.

Some diseases have, it may be said, been abolished in the army through the exertions of military Medical men. Typhus fever, for example, which, even so lately as the days of the Peninsular War was literally *the* army disease, to such an extent did it prevail, is now next to unknown; dysentery of a severe type is never now met with except in the tropics; and scurvy is all but unknown, except under very unusual circumstances. So also with small-pox: the care with which vaccination and re-vaccination is performed, and other hygienic measures adopted, has brought cases of this disease to their minimum among the troops. The efficiency with which protective measures are employed have rendered such a thing as a general epidemic of infectious disease, scarlatina, for instance, unknown; and although, unhappily, means have not yet been discovered to similarly exclude cholera, when that dire malady sweeps over a military station as it does in

India, nevertheless by removing the troops away from the locality to a more healthy district, a great deal has been achieved to diminish its ravages. This measure, adopted first with regard to yellow fever in the West Indies, was practised in India so long ago as 1825, and yet, to judge from recent printed statements, the measure would seem as but of yesterday. In both cases its authors were army surgeons. Many other sanitary improvements of the greatest importance to the soldier have been introduced by army Medical officers; many more would have been so had their recommendations been fully acted upon. Yet, what is by no means encouraging is the fact, that in comparatively few cases are the names of their actual originators mentioned in connection with them. You hear that such and such improvements were introduced by *Lord* this or *Lord* that; but who ever hears a word about the pertinacity with which the necessity for them had been urged by Doctor So-and-so?

Turning to matters more purely connected with curative medicine and surgery, permit me to allude to a few improvements effected by army surgeons. As they were the first to study the diseases peculiar to the tropics, such as yellow fever, cholera, liver disease, dysentery, and sun-stroke, so the first advances made in the treatment of those affections were inaugurated by them. They also it was who first gave to the Profession connected accounts of the etiology and pathology of those affections. Syphilitic diseases were, from the nature of circumstances, more especially brought under the notice of military surgeons. The ravages of those affections, far greater than they have in our day been, were first counteracted by them; and if at one period mercury was pushed to an extent that would now be deemed unjustifiable, they it was who instituted comparative statistics in regard to the relative success of various means of cure, thus laying the basis of our present improved method of treating what now seems to be a much modified form of disease. To army surgeons the Profession is indebted for the first protest raised against the extent to which in former days calomel was administered in the treatment of diseases of the tropics, and the late Dr. Mackintosh—himself, by-the-bye, an army surgeon—tells us how the first Medical officer in India who protested against the then prevalent practice of profuse salivation, was not only placed under arrest for entertaining heretical opinions, but it is to be feared had his prospects for ever blasted, as an encouragement for his brethren. So also with the old system of profuse bleeding. The first note of alarm in regard to the practice so far as I can learn, was sounded by an army surgeon, a very remarkable man, notwithstanding his somewhat Quixotic tilt against "The Fallacies of the Faculty." That note was taken up by Inspector-General Hume, who is still alive, and who, in a work published about 1840, showed some of the abuses attendant upon the system.

With regard to the treatment of gunshot injuries, army surgeons have naturally monopolised, at least to a great extent, this kind of wounds. The teachings of the Peninsular War in regard to them have been enumerated by Sir Charles Bell and Mr. Guthrie; many of the principles laid down by them being confirmed by the more recent experience gained in the great war so lately ended. I allude more especially to the necessity for securing a wounded artery above and below the seat of injury, the treatment of penetrating wounds of the chest, and the question of primary and secondary amputation. With regard to individual operations, it is at once allowed that almost all the improvements in their manner of performance have come from our civil brethren. We, as a body, can only claim to have adopted them. Permit me to observe, however, that the hurry and confusion of active service, or the surgery of war hospitals, scarcely afford conditions under which to practise experimental methods, for our surgery, like the conditions in which we are placed, must be somewhat rough. But, let me add, it must be ready as it is emergent.

It would be unbecoming in me, and unjust to the memory of the greatest of all surgeons, military or civil,

did I not make one brief allusion to John Hunter, although to you who know so well the literature of his works, it is unnecessary to pass all in review. In 1793 this great man occupied the position of Director-General of the Army Medical Department, and re-organised the Medical arrangements for the army, then being assembled for service on the Continent. With regard to his works on the blood, inflammation, and gunshot wounds, his researches in regard to syphilis, his improved treatment of aneurism, and his labours in elucidation of our common science, all of us are alike still willing to pay him homage. It may not be out of place to remind you that this army surgeon has been justly described as "the greatest man in the Medical Profession, either in ancient or modern times;" that in 1759 he entered the Medical service of the army, in 1762 accompanied the forces engaged in the war with Spain, in 1786 became Surgeon-General, and at the time of his death was fulfilling the important duties connected with the position of Director-General, as well as the highly honourable position of surgeon to St. George's Hospital.

The limits within which my remarks must be compressed prevent me from further enlarging upon this part of my subject, being anxious as I am to glance at a few of the lessons to be gathered from the late great war upon the Continent. Many of those lessons are of great value, not only to the army Medical officer, but to the practitioner in civil life; involving, as they do, points of immense importance in regard to the management of individuals when suffering from wounds or operations, or when prostrated by diseases incidental to campaigns or by those affecting the general conditions of the masses. I can pretend to no more, however, than to solicit your attention to a few out of the number.

With regard to hygienic measures, the experience of the Franco-German War indicates three very remarkable circumstances. Within besieged Paris, for example, great as the mortality continued to be throughout the winter of 1870-71, and rife as were the causes of disease in operation—including a condition of semi-starvation, insufficient fuel, physical and moral depression, together with the prevalence of epidemic diseases among the populace—such was the energy shown by the health authorities, and the discretion of the measures dictated by them, that the death-rates were maintained at a mere fraction of what they had been, not only on the occasion of the previous siege of the same capital in 1590, but also of those of other sieges in more recent times. So it was with other French cities, as Metz and Strasbourg. So, also, it was among the besiegers of those places. On former occasions history tells us that the forces investing a city suffered by disease to an extent only in a degree less than those invested; and, with regard to Metz, that a former besieging army—that of Charles V., in 1552—had actually to withdraw in consequence of the frightful ravages of disease in its ranks. But all this has now been changed. The observance of hygienic principles has enabled commanders to maintain a besieging army in a state of physical efficiency equal to that enjoyed by troops in ordinary quarters. But, and in the second place, it has been demonstrated that circumstances may arise in which the existence of one radical defect may neutralise all the best-directed efforts of hygiene, so long as that cardinal defect is unremoved. Thus, all the measures that it has been possible to take have failed to neutralise or compensate for the evils arising from the adoption—as hospitals for wounded—of buildings unsuitably constructed; of those occupying defective positions; and of those, let me add, that have been impregnated with human emanations, such as churches, ball-rooms, hotels, theatres, and so on. In none of these were hygienic measures capable of preventing the occurrence of hospital diseases. In the third place, there have occurred during the late war, as in previous campaigns, and as there must be in all, occasions on which the pressure or necessities of military operations for the time being supersede all questions of hygiene. A military end has to be attained, a rapid movement effected; the sacrifice of a certain number is inevitable; it is taken

into account, and while the movement is being effected there is neither time nor room for hygiene.

We have learned that it is unsafe to draw conclusions from observations made under one set of conditions, and to apply them in emergencies of a totally different nature. Thus, in civil hospitals, where the establishments are not only themselves arranged with the greatest care and completeness for their purpose, the staff numerous and perfectly trained, but the cases under treatment at any one time inconsiderable in number, the rules, there suitable, cannot safely be applied to extemporised war hospitals, established in unsuitable buildings, often with few and imperfectly-trained attendants; with food, clothing, and cleanliness limited; and with wounded being brought in large numbers for assistance, as is the case after a modern battle. Neither, again, would rules of treatment, suitable in establishments such as these, be applicable where wounded had to be carried with their several forces, whether advancing or retreating; or where from circumstances it was necessary to have them transported to a great distance. Nor must I omit to observe, that the general arrangements for the wounded of armies, which are suited for civilised countries, are totally inapplicable in operations against an uncivilised enemy, or at least one whose civilisation is not according to the western model. In the one case, the civil population have ever shown themselves ready to extend help to those disabled in battle: a wounded soldier has long ceased to be an *enemy*, his life is held sacred by foe and friend alike, and now he receives the additional security of the Red Cross of Geneva. Left wherever he may be, alike in the hands of the hostile forces, in an enemy's country, or upon his own natural soil, he is sure of care. How different all this would be, say in India, in Africa, or in New Zealand! We have, alas! too many instances where the wounded, during late wars, were barbarously put to death by those enemies into whose hands they had unhappily fallen. It is, therefore, obvious that arrangements for their protection, unnecessary in the one case, become matters of absolute necessity in the other.

Another point of great importance seems to me to have been indicated in the late war. The Prussian Government had sent with particular *corps d'armée* one or more surgeons of eminence, whose duties were merely consultational, the venerable Stromeyer being among their number, and their chief. The nature of the services rendered by these men is acknowledged to have been very great, and seems to me to indicate the propriety of a similar plan being adopted in our own army when next engaged in war. Men of great experience among war hospitals would, in such a case, be invaluable merely for their opinions in regard to the suitable treatment to be followed in particular cases, relieving the *executive* surgeons of much responsibility, and would doubtless be the means of saving many lives. Thus, it is only necessary to indicate how important would be the results were it authoritatively said, "Treat that limb conservatively," or "Time will be lost if you attempt to save it," "This man, wounded through the chest, may recover if retained where he is," "That man must be transferred elsewhere," and so on.

Adverting to questions of a more purely professional nature, many important lessons have been learnt, and teachings of former campaigns confirmed, by the late war. Let us take conservative surgery as an example in point. Unfortunately, the rate of mortality was very great among the wounded; it was very large among those who had been subjected to operation; but so it was, with very rare exceptions, among those who were treated conservatively. As a rule, it may be said that a more numerous and better trained staff is required for the successful practice of conservative surgery than for that of a more radical description. It would seem that the risks of hospital diseases are increased by attempts at preserving shattered limbs; that in many instances secondary operations have to be performed while the patients are in an unfavourable condition; and that for any other than stationary hospitals this method of procedure is, as a rule, unsuitable.

I have already alluded to the lessons we have learnt from the late war in regard to penetrating wounds of the chest. In cases where the wound implicates the upper portion of a lung, and has gone clean through, or otherwise escaped from the thorax, we would not now despond, but rather treat the patient with a considerable degree of confidence as to his speedy recovery. We would hermetically close both openings of the wound; would place the patient in a hut or tent where the temperature admitted of being regulated; would, in the first instance, direct our measures to the state of more or less collapse or *shock* into which a man thus wounded is sure to fall; would combat reaction some forty-eight hours afterwards; and finally, in due time, support and nourish our patient, keep him quiet, but at the same time cheerful.

In cases of wounds in the near vicinity of the large joints, our first consideration would be—Can an apparatus be so applied as to immobilise the member? our next—Can our patient be treated under conditions of a nature to render conservation probable? In a gun-shot fracture of the femur we would in like manner ask—What are the conditions under which the patient may be treated? and having ascertained them would now have relatively little difficulty in deciding upon the method of treatment to follow. And what about that very vexed question—gun-shot wounds penetrating the knee-joint? I think that although during the war some instances have undoubtedly occurred in which life and limb have been saved, the general conclusion arrived at is that immediate amputation is, as a principle, the plan of treatment to follow. With regard to excisions of joints, the results of operations in cases of disease occurring in metropolitan and other civil hospitals give no safe indications of what those in war would be. Take, for example, the knee-joint: it may now be taken as conclusive that for wounds in battle excision of this articulation is no longer justifiable.

In regard to the very important subject of hospital diseases, the experience of the late war and inquiries arising out of it, in France, in England, and elsewhere, have done more to give us a clear insight into their etiology and pathology than we have hitherto possessed, and thus the better enable us not only to treat them when they occur, but to guard against their occurrence among the wounded. M. Démarquay, in Paris, has in a manner made this investigation his own.

Finally, I would briefly enumerate, as they were written at the time, a few of the other lessons to be gathered from the great drama so recently enacted, confining myself to that portion of it with which I was more immediately connected—namely, the siege of Paris. These lessons are:—

That in all arrangements having reference to war, the requirements of the wounded demand pre-eminent attention.

The necessity and importance, in a public point of view, of the highest professional skill, the best attendance and attendants that are available, have been demonstrated.

The importance also, in a public point of view, of the services of surgeons made itself apparent during the siege, and was then frankly acknowledged by the authorities, civil and military.

It was well known that a considerable amount of the mortality in hospitals was the result of administrative power being in the hands of non-Medical persons; and demonstrated that those conditions required to be altered on future occasions, that all the needs and necessities of sick and wounded men should be controlled and ministered to by professional men.

The superiority of huts and tents over permanent buildings as hospitals gives rise to the question whether, in the event of its being possible on future similar occasions to use these alone, this ought not to be done.

The want of properly-trained *brancardiers* for the removal of wounded men having been the cause of much suffering to the latter, it is incumbent to have for the future specially-instructed men for this purpose, as well as for attendance on them in hospital.

It is, moreover, essential for the comfort of the wounded that the carriages used for their transport from the field of battle to the hospitals should be of the lightest description compatible with strength, their springs of the best material, elastic and in all respects well finished; and that the conveyances be well horsed, so that injured soldiers may be conveyed as rapidly and with as much ease as possible to the hospitals provided for them.

But I must have done. I have in my review carried you over a considerable variety of subjects. I have looked at each in turn from the point of view in which it concerns the military members of our Profession; and if in all cases the points to which allusion has been made have, perhaps, not been within the sphere of our brethren in civil life, they have, I would fain hope, indicated to you the extensive programme it is necessary that the army surgeon should make himself acquainted with, in order that he may efficiently perform the high duties that fall within his province,—duties responsible and important in themselves, on the one hand affecting the efficiency of our army, on the other involving the highest aims of our common Profession, in combating disease, in ministering to the wounded, often in times of greatest peril, and in helping, as far as in us lies, to reduce the amount of bodily suffering and misery among the classes of the community with whom we are associated.

CLINICAL NOTES AND OBSERVATIONS.

By HENRY LEE,

Surgeon to St. George's Hospital.

No. XII.—DISEASES OF ARTERIES (*Continued*).

Aneurism of Popliteal Artery—Ligature—Mortification.—Thomas Evans, æt. 30, a servant in a gentleman's family living in Dorsetshire, has always enjoyed good health.

February 9, 1856.—Last Christmas, whilst jumping over a gate he slipped and struck the inner side of the right thigh at its lower part. He felt an unusual amount of pain at the time and walked home. Then he found a small firm tumour among the tendons at the back of the thigh, not very painful, but evidently pulsating. He continued at work till within five or six days, feeling but little pain in the tumour, which had, however, gradually increased and acquired the size of a 6-yard bandage (rolled). Within the last few days the tumour had more than doubled its former size, although he had taken no unusual exertion. He is a healthy-looking man, the tumour pulsates distinctly and visibly, and the pulsations can be felt from the centre of the rectus in front round to the external hamstring behind. It is soft to the touch and very painful; a bruit can be heard over it; the pulsations are not distinct over the inner side of the thigh; the pain shoots up the course of the femoral artery, indicating to the patient its exact course; the leg occasionally becomes dead, but does not seem any colder than the other. Pressure was first used, the force being applied where the artery passed over the pubes, but the instrument irritating the skin, was after two days changed for another, but no bearable pressure stopped the pulsation. Signorini's instrument was applied on the 11th. On the 13th Castes was again applied, it being more effectual in stopping the pulsations. The aneurism, however, got larger and larger, and the skin over it became very tense and red, and on the 14th it was determined to operate; pressure was left off therefore. On the 16th the thigh over the tumour measured 18½ inches in circumference, and on this day a ligature was placed on the femoral artery at the commencement of the middle third. The needle was passed around quite close to the artery, but unfortunately a large vein (possibly the femoral) was wounded, which bled very freely for a few seconds, but the bleeding stopped when the ligature on the artery was tightened. The wound was

drawn together by two stitches, and then a pad of lint retained on it by plaster. After recovering from the chloroform the patient complained of great pain at the back of the ankle; temperature of the right calf, 89° F., of left, 91° F.

February 17th.—Temperature of right leg, 82° F., left 90°.

18th.—Calf swollen and tense; foot looking rather dusky; temperature, 84° F., left R., right 92.

19th.—The calf of the right leg oedematous and very painful; foot more blue and dusky, as far as just over the ankle joint and is cold to the touch, and devoid of sensation. Temperature of right foot, 78° F., left, 90° F. Aneurismal tumour free from pain; soft and diminishing in size; thigh measures 17 inches.

20th.—Wound looking healthy; foot and leg for two or three inches above the ankle quite void of sensibility, and mottled with blue spots.

26th.—The thigh over the tumour measures 16 inches. The tumour is firm to the touch; less pain.

March 4th.—The site of aneurism measures the same or nearly as the leg of sound limb; the wound over the femoral has healed favourably, all but the spot for the ligature.

March 24th.—Since the last date he has continued on the whole in very good health; but having been on two occasions troubled with great pain in the right hypochondriac region, the ligature gave way on the 6th, and the wound has closed all but a small point. A line of demarcation between the dead foot and the living part of the leg has formed about two inches above the ankle-joint in front, but extending much higher behind.

Amputation below the knee was performed on the 5th of April. The operation was followed with scarcely any bleeding; the veins were obstructed with fibrinous clots; the cellular membrane between the muscles and under the skin was infiltrated by ill-formed pus. A line of demarcation had formed considerably lower than the point of amputation. A large quantity of putrid fluid occupied the cellular tissue at this part. After the amputation this patient continued in a very low state. Many abscesses formed in and about the knee-joint, which previously had afforded no indications of disease. The aneurismal tumour suppurated and was opened, and at the extirpation of several months this patient was sent to Margate.

A man, æt. 51, was seen by Drs. Keyworth and Swaine at midnight on the 21st of September, 1855. He was then lying on his back in bed, bathed in a clammy perspiration, indicative of great anxiety and distress. He complained in hurried accents of a dull heavy pain within the thorax, extending inwardly from nipple to nipple and further, of a sense of weight and aching somewhat below and to the left of the umbilicus. He had but partially rallied from a state of collapse, and Mr. Keyworth drew attention to the remarkable fact that not only had the lower extremities failed to participate in the reaction, but also that neither in the femoral arteries nor in the popliteal was any pulsation discoverable. Mr. Keyworth had been in attendance since 10 p.m. The patient, whose intellect was clear, related that during the day he had ascended a hill on foot, under a burning sun, dined heartily at a friend's house, and afterwards returned to York partly on horseback and partly by train. Walking home from the York station he was, in front of his own house, seized with a sudden and violent pain, "as though," to use his own words, "his chest were torn open from side to side by some outward force." It was instantly followed by a second "agonizing" pain, which seemed to dart from mid-sternum, down the left of the spinal column, and only to be arrested a few finger's breadth below and to the left of the umbilicus, at which point of arrest he (the patient) thought he could hear a distinct crack. The next, almost a simultaneous occurrence, was loss of power in the left inferior extremity, and very soon after in the right also. Carried into his house for a brief interval he became bereft of conscious-

ness, but not until after a repetition of the lacerating pain. Referred this time not the anterior, but to the posterior part of the thorax, from scapula to scapula. On recovering consciousness he vomited his still-undigested midday meal, and felt relieved thereby. Mr. Keyworth now arriving caused him to be undressed and carried to bed, where a judicious use of diffusible stimulants was resorted to with the aforesaid partial success. Meanwhile the kidneys acted copiously, the urine being clear and of a pale amber colour. Dr. Swaine, who had not examined the patient again since March, found the cardiac sounds hardly at all changed from what he recollected them to have been at that period. Over the track of the aorta, however, two finger's breadth above, but to the left of the umbilicus there was an audible bellows murmur (under even a lightly pressing stethoscope) accompanying each systolic action of the heart. Two or three finger's breadth below this point, all pulsation had ceased, whilst a little lower still at the part where the aorta should bifurcate into the common iliac arteries, a tumour the size of a goose's egg, and of doughy hardness, could be distinctly felt. Taking this extraordinary and withal very marked train of symptoms in connection with the previous and present signs of cardiac disease, Dr. Swaine did not hesitate to express his conviction that a circular or transverse rupture had taken place of the internal and middle coats of the aorta near its cardiac orifice; and that the blood stream, partially diverted from its natural channel, had dissected for itself a false passage between the middle coat and the external fibro-cellular sheath of the artery. That meeting with an impediment to its progress in the diverging iliacs it had there speedily accumulated and become consolidated, so as to compress and obliterate the true calibre of the aorta itself, and to arrest the circulation at this point; in short, that the case was one of so-called dissecting aneurism. This explanation suggested at once by Dr. Swaine, in all its details was readily adopted by Mr. Keyworth. Under all the circumstances it was natural to look forward to a fatal termination of the case within a very brief period. Complete rest and abstinence were recommended in the first instance.

On the 22nd of September (the following day) the physical signs all continued unchanged; considerable general reaction had, however, taken place; the thoracic and abdominal viscera, and even the brain manifested much congestion. The countenance was flushed, the skin partially hot, the pulse quick and bounding, the carotids labouring, the bowels constipated, the urine copious, but deeply coloured, and intensely acid. The patient complained much of headache; of a dull throbbing pain behind the sternum, beneath the right clavicle, and in both arms; and lastly, of a sense of weight and oppression over the upper part of the abdomen, and at the seat of the abdominal tumour already adverted to. Here was a state of congestive reaction obviously due in a great measure to the sudden and excessive limitation of the sphere naturally allotted to the blood stream. Venesection was urgently required; it was delayed, however, for another day in deference to the prejudice of friends, and an abortive attempt made in the meantime to relieve the pain by local depletion.

On the 23rd September, the third day, the symptoms continuing unmitigated, about twelve ounces of blood were withdrawn from the left arm, with marked and permanent relief to the sufferer. The blood itself yielded a large proportion of coagulum and a flabby dingy honey-combed crust. No attempt was made to operate upon the bowels until the fifth day, when a full dose of castor oil produced one very copious and well-conditioned motion. From this time the general symptoms began to mend, the appetite and strength slowly to return, the lower extremities to recover a fair amount of warmth, and also of power. Still the femoral arteries continued to fail in their office, and they could now be detected and traced in their natural course, in the shape of hard fibrin-filled cylinders. The bellows sound above and to the

left of the umbilicus was less intense; the tumour diminished in size, although still palpable, and still sensitive upon deep pressure. Three weeks later the patient felt well enough to drive out in an easy carriage, but as the winter approached he again began to droop. He caught cold; cough with rust-tinged expectoration was followed by pleural effusion on the left side, and eventually by general anasarca. His sufferings were great and protracted, nor was he released from them until the 21st of December, exactly three months from the period of his violent seizure.

Examination thirteen hours after death: both lungs much congested, especially the left, which also presents patches of emphysema; the left pleural sac contains about thirty ounces of pink serum; heart very large, firm and heavy; ventricles filled with dark grumous blood; cavity of the left ventricle not inconsiderably dilated, its walls of enormous thickness, the cut surface being of a dingy russet colour, very compact, and appearing to the naked eye as if bereft of much of the natural fibrous structure. Both the mitral and aortic valves are "insufficient" to prevent the reflux of fluid through them, the former are essentially thickened at its margin, the latter not thickened, but on the contrary, attenuated and eroded patchwise, on their arterial surface. Both the semi-lunar valves and the commencement of the aorta are much distended, and seem to have lost their contractile power. A few lines below the point where the left subclavian artery is given off a transverse or circular rupture of the middle and internal coats of the aorta has taken place, leaving the inferior portion of the artery attached to the upper portion only by about one-sixth of the circle at its posterior part. The edges of the rupture are partly smooth as if cut with scissors, partly jagged and reflected from the ruptured part downwards, the fibro-cellular sheath of the artery has (with the exception of its posterior part, which is still adherent) widely separated from the middle coat, the interspace presenting along its entire length a succession of little flattened blood clots, some of which cohere through the medium of lymph shreds with the inner surface of this fibro-cellular sheath. At the bifurcation of the aorta into the common iliac arteries is found impacted between the external and middle coats, a russet-coloured hardened fibrinous coagulum, as big as a rook's egg, this coagulum has, on the one side, become partly organised and adherent to the fibro-cellular sheath; whilst, on the other side, it firmly and thoroughly compresses the true canal of the aorta. Below this point of compression, the left common iliac artery presents a firm cord, and on incision a compact hard cylinder of brown fibrin. The right common iliac is pervious, and contains some dark fluid blood. From this artery a common slate pencil could, without much difficulty, be passed into the aorta at the point of its compression. Latterly, Mr. Keyworth had again detected slight pulsation in the right femoral artery. Several of the intercostal arteries appear injured: the cœliac axis, the superior mesenteric, the renal arteries are severally in good condition, the inferior mesenteric obliterated, the old canal of the aorta is replete with dark grumous blood. Its internal surface or inner coat presents numerous patches smaller and greater of atheromatous degeneration in its various phases, up to the condition of semi-cartilaginous hardness.

The following case occurred in the practice of Mr. G. Austen, veterinary surgeon, Eaton Square:—

The subject was a full-sized horse in very good condition, and about 8 or 9 years old. About one year previous to his death, he had several attacks resembling "spasmodic colic." These attacks became more frequent and also more intense in character, and those which occurred a short time before his death were associated with lameness of the off hind limb. The last attack occurred in August, 1852, when the groom was driving him in a "dog cart." He then fell acutely lame of the

same limb that had before been affected, and so intense was the lameness on this occasion that the groom thought the horse's leg was broken. With some little difficulty he got the horse home, and at once sent for Mr. Austen, who found the poor beast suffering intensely. His pulse was very quick; his respiration quick; sweating profusely, and showing signs of great abdominal pain; but what struck Mr. Austen as being very singular was, that although the animal's surface was wet with perspiration, the hind limb before alluded to was quite dry and *deadly cold*, and completely paralyzed, both as regards motion and sensation. The horse lived only twenty hours after the commencement of the last attack, during which period he suffered severely, laying down, getting up, and throwing himself about with great violence.

Post-mortem.—The viscera of the thorax, and also of the abdomen were quite healthy, as were also the brain and spinal cord. In tracing the larger vessels from the heart, it was discovered that the right internal iliac and its divisions for the distance of at least eight or nine inches were completely plugged with concentric layers of fibrin, which could easily be separated from the internal serous lining membrane of the vessels.

In concluding the present series of communications, I take the opportunity of correcting one or two inaccuracies which occurred in recording a case in No. 1V. The case was described from memory, and I had not any notes of the *post-mortem* examination at hand. The opinion to which I referred as having been given was, that the case was one of accumulation of fœces. My own opinion was that the symptoms depended upon a twist in the intestines, and for this I proposed for consideration the propriety of making an opening into the abdomen. On a *post-mortem* examination a portion of the intestine in the pelvis was found almost in a gangrenous condition, but no apparent cause for this was detected. Some fœces had passed, and some undigested castor oil. Under the idea that there might be some mechanical obstruction to the passage of fœces, I moved the intestines from side to side. This was followed by no relief, but rather increase of distress. In a case mentioned to me by Dr. Ogle, a condition such as I conceived might have existed, was shown to be present on a *post-mortem* examination. A fold of small intestine was simply twisted upon itself, so as to obstruct the passage through the intestines. This twist was undone without the slightest force, and if pressure had fortunately been applied in the right place, might doubtless have been undone during life; and it is not impossible that this may actually have occurred in the case referred to.

In a second case, which Dr. Ogle lately requested me to see, there was complete obstruction, and an opening into the abdomen was contemplated. Fortunately in this case it was not performed, as the cœcum was firmly bound down by a strong band in the situation of the spleen. In a third case, in which I operated for colotomy, the obstruction was not in the large intestine, but in the small. The small intestine was here opened, and adhered firmly to the sides of the aperture. The patient lived some days. In a fourth case the descending colon was opened. The patient was greatly relieved and lived three weeks. He ultimately died of malignant disease of the liver.

A TELEGRAM from Cape Town states that a bill to repeal the Contagious Diseases Act has passed both branches of the Legislature. The chief opposition to repeal here, as in England, came from officials.

THE action raised by the lady medical students against the Senatus Academicus of the University of Edinburgh was tried before Lord Gifford last week. The debate occupied two days. His lordship deferred judgment.

MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS OF IRELAND.

DR. DAUBY in the Chair.

Dr. J. MACEE FINNY read a case

ILLUSTRATING THE GENERAL PHYSIOLOGICAL ANTAGONISM BETWEEN ATROPIA AND MORPHIA.

Miss C., *æt.* 25, a lady of nervous temperament, and who had on several occasions suffered from various forms of neuralgia, consulted me for severe neuralgia in the left side of her face and head, produced by a dental operation to which she had recently submitted.

Having, on previous occasions noticed the hypodermic employment of morphia and atropia combined, to be followed, in this lady, by the happiest results, I determined to use this mode of treatment again for the present existing suffering.

I may here observe that my experience coincides with the teaching I acquired while a pupil of Dr. Stokes—namely, that to obtain the best results from the use of hypnotics, it is advisable to administer the drugs at the usual hour of sleep, so as to anticipate, as it were, the normal process of habit.

In accordance with this principle, I paid my patient a visit at 10 o'clock in the evening, purposing to inject under the skin of the arm $\frac{1}{2}$ grain of acet. morphia, along with 1-50th grain of sulph. atropia.

The addition of the atropia diminishes the tendency to nausea, so constantly following the administration of morphia alone, and produces anodyne effects not to be obtained by morphia.

As, however, my atropia solution had been in my possession for over three months, and as I noticed several fungoid bodies floating through it, I conceived it had lost much of its strength, and that I ought therefore, so as to obtain its full effects, to give of it a larger quantity than usual. Acting on this conception—a proceeding which the circumstances that followed made me greatly regret—I administered subcutaneously double the usual quantity of the atropia solution, along with $\frac{1}{2}$ grain of morphia. In about twenty minutes, Miss C.'s maid hastily summoned me to her bed side.

The condition I found her in was quite new to me. The symptoms were as follows:—Complaining of great cold, so that she was shivering and trembling all over (to which perhaps alarm may have tended), and her teeth chattering, her feet and hands were cold, although a hot jar was to her feet, and additional blankets covered her. The tongue was dry, parched, and rough, and this condition evidently extended to the pharynx, as she complained of dryness of the throat, and constantly asked for drinks, although, when they were given, she was hardly able to swallow them. Her speech was thick and articulate; she complained of dimness of vision, saying she could not see me, and that flashes of bright light passed before her eyes. The pupils were much dilated and unaffected by approximating the light of the candle towards them. The pulse very small, up to 130. Respiration 32, and very shallow. On being questioned why she could not draw a deep breath she replied that she was caught on attempting to do

the case was evidently one of atropism, produced by an overdose of the alkaloid. Hoping the ill-effects would shortly pass away, I remained beside her to watch the result—but instead of becoming better, I soon saw the case change, from one of simple interest, into one of no small anxiety to me.

In about ten minutes, she evidenced great uneasiness, tossed about, flexing and extending her arms and legs; she now became delirious, talking on various subjects, being quite unaware of my presence, and imagined several persons were in the room, giving directions to them on various domestic matters. She grasped at imaginary objects in the air; and from no doubt, the parched state of her throat, frequently attempted to pass her finger to the back of the throat, and frequently succeeded, on one or two occasions, in producing vomiting. The pulse still kept high, and I determined to send for additional aid and advice. Before doing so, however, the thought occurred to me to try the effect of a dose of morphia as a general physiological antidote—as the recollection of cases of belladonna poisoning having been successfully treated, on

this principle by Dr. Wharton, flashed across my memory. (These cases are detailed in the *MEDICAL PRESS* for 1862.)

Accordingly I injected $\frac{1}{2}$ grain of the acet. morphia.

In less than five minutes I observed the restlessness and jactitation cease, the skin to become warm, and the respiration fall to 20, while the pulse came down below 100, and was fuller. In a few minutes afterwards—ten altogether from the second injection—my patient was sound asleep, and in a fair way to spend a quiet night. After remaining in the house about half an hour longer, I took my leave, and in the morning I learned she had slept well, had taken a hearty breakfast and that the neuralgia had entirely disappeared. She visited me in my study in the afternoon, and with the exception of slight inconvenience arising from the still dilated condition of the pupils, she expressed herself as being as well as ever.

The points of interest which this case furnishes to the scientific and the practical man alike are neither few nor insignificant. Whether the quantity injected would have, if left to itself, ended in the same happy way, or otherwise, I am unable to state, but the points of resemblance between the symptoms just detailed, and those of a poisonous dose of belladonna, were too striking to buoy me up with any such hope as that.

Dr. John Harley, in an exhaustive and most able treatise, states that the fullest medicinal dose of the sulph. atropia hypodermically employed is 1-48th grain, after which the following symptoms may be expected.

“After 10-15 minutes an acceleration of the pulse, 20-70 beats with decided increase in the force of the cardiac contractions, and of the arterial tone; a general suffusion of warmth, a slight throbbing or heaving sensation in the carotids, and a feeling of pressure under the parietal bones; giddiness, drowsiness, or actual sleep, with a great tendency to dreamy delirium, and in women slight occasional startings; complete dryness of the tongue, roof of the mouth, and soft palate, extending more or less down the pharynx and larynx, rendering the voice husky, and often inducing dry cough and difficulty of deglutition. No difference will be observed,” he says, “in the rate of respiration, except (as may happen in a nervous woman) a little emotional excitement on the sudden accession of giddiness. After continuing about two hours, the dryness of the mouth is suddenly relieved by the appearance of a viscid acid secretion of an offensive odour, like the sweat of the feet; as moisture returns to the mouth the pulse is observed to fall, and it now rapidly resumes its ordinary rate.” That is, the pulse remains high for over two hours at the least.

“A larger dose, 1-32 gr., produces, in addition to the above, sleep, or instead of sleep a little meddlesome delirium, and the patient will require attention to prevent him getting out of bed.”

It must, however, be borne in mind that while both children and pregnant women are remarkably insusceptible of the action of belladonna, it is equally the truth that the weak and those of excitable temperament are very readily and powerfully influenced by the alkaloid. “The 1-96th gr. of the atropia salt (writes Dr. Harley), will produce as great an effect upon a delicate nervous woman as 1-60th gr. upon a man of average strength.”

On looking through the recorded cases of poisoning by belladonna, in which the treatment was based upon the physiological antagonism of opium or morphia, I find two cases detailed by Mr. Benjamin Bell, in the *Edinburgh Medical Journal* of 1857.

The first case given by Dr. Bell was that of an aggravated case of sciatica, in which, after having failed to give by morphia more than temporary relief, he determined to employ atropia. He accordingly injected behind the great trochanter $\frac{1}{2}$ gr. of sulphate of atropia. This large dose he was led to use from having safely employed 1-12th gr. in a former instance under the skin of the forehead for severe facial neuralgia, and he thought he might, at such a distance from the sensorium as the thigh, with equal immunity and benefit employ a larger dose. Almost immediately the pain was relieved, but in a short time symptoms very similar to those detailed above: as having occurred in my own case, ensued. “Under these circumstances,” writes Dr. Bell, “being acquainted with no more promising plan of treatment, I had recourse, with some confidence, to the subcutaneous injection of morphia. I injected without delay 25 minims of the double strength solution of morphia into the gluteal region of the opposite limb, which happened to be next the edge of the bed. This was about 5 p.m. Almost immediately a decided change for the better was perceptible. He became considerably calmer,

and swallowed a little water without much difficulty. I visited him again at 7.30, and was glad to find he had been sleeping quietly in that posture for an hour and a-half. On the following day before noon I found him entirely relieved from pain and in good spirits.

It is interesting to note how varied are the opinions of eminent men, and how directly opposed they are in regard to this vexed question of antagonism of morphia and opium to atropia and belladonna. They may be ranged in two lines, the one maintaining that these alkaloids are as strikingly general physiological antidotes as nicotin and strychnia are supposed to be, and as physostigma and atropia, denying that any physiological antagonism exists whatever between these drugs, except as regards the pupil.

Between these two extremes lies, I believe, the happy mean—the truth—to come to life more vigorously, when further observations have been recorded of a properly devised series of experiments, and of clinical cases carefully and truthfully related.

In the conclusions deduced by Dr. Harley, I fully coincide, when he says—"1. That in medicinal doses the essential effect of morphia (hypnosis) is both increased and prolonged by the action of atropia, whether induced previously or at any time during the operation of the former. 2. That atropia relieves, and, if given simultaneously or previously, prevents the nausea, vomiting, syncope, and insomnia, which frequently result from the action of opium;" but I cannot go with him when he states "that all the effects of atropia other than that of dilating the pupil are intensified and prolonged by the action of morphia, induced previously, or at any time during the operation of the former, whether given in medicinal or toxic doses."

Dr. Harley has with much labour and care tabulated forty-three cases of, as he considers it, the supposed antagonism of these alkaloids. Table I. contains twenty-one of opium poisoning, treated by belladonna. Table II. twenty-two cases of poisoning by belladonna treated by opium. These tables I have very carefully studied, and I confess that no other conviction is forced on my mind than that opium or morphia is directly antagonistic to belladonna.

In conclusion, I would impress the advantages of using the antidote by the hypodermic method for the following reasons:

1. It can be employed when the patient is unable, or from delirium, unwilling to swallow.
2. The rapidity and certainty of the antidote thus applied.
3. The quantity given can be accurately measured.
4. The dose can be repeated as often as may seem necessary.

Dr. M'SWINEY gave the particulars of a similar case; 30 minims of liquor atropia were given to a man, *et. 40*, in mistake for 30 minims of Battley's sedative solution. Almost immediately after the dose was taken it produced the most violent excitement on the part of the patient. He jumped about, screamed, declared he was dying, and raved and stormed in the most excited manner. The mistake was immediately discovered, and an emetic was at once administered, which acted. He also got a dose of brandy and of aromatic spirits of ammonia, and hot jars were applied to the feet. At 7 o'clock—three and a-half hours after he got the poison—he was seen, and 30 minims of hydro-chlorate of morphia were given to him. He was just able to swallow the dose, and his condition was then one of entire insensibility. He appeared to be perfectly anæsthetic, as pinching the skin did not produce the slightest response. The eyes were open and staring; the irides might be said to have disappeared; the pulse was very quick and small; the surface of the body was cold and bathed in perspiration; the respiration was slow. Doses of twenty minims of the solution of hydro-chlorate of morphia continued to be administered at intervals for an hour and a-half until he got three drachms of the solution, or one grain and three-quarters. After the first drachm was given the pupils slowly began to contract, and there was no appearance of a return to consciousness. He was carefully watched, and by 12 o'clock that night consciousness had returned, and he spoke correctly. As there was a great tendency to drowsiness, he was not allowed to sleep until the following morning. At that time his consciousness became perfectly restored. He was able to state that he could not see, and although he was well in all other particulars, his pupils were insensible to light. No further bad consequences resulted, and the man was now perfectly well.

Dr. HAYDEN said the case which had come under his observation was not, in some respects, a parallel case to that of Dr. Finny, for, in the first place, the toxic agent was the berries

of belladonna. The child came in to his dinner, but the mother noticed that he was strange in manner; he took very little food, but that which he did take he ejected, and there was found in the ejecta a dark matter, which appeared on examination to be the husks of the berry. He exhibited all the symptoms characteristic of belladonna poisoning. He placed the boy immediately under treatment, gave him a dose of Dover's powder, and on the following day he was comparatively well. The whole of this subject was of the deepest interest; and not less so, because they knew so little of the causes that were in operation in the production of these various results. They knew something in a general way of the action of belladonna—that it was a stimulant of the vaso-motor system and of the vascular system. Many of the symptoms that followed the toxic action of belladonna might be explained in the same way; for example, the rapidity of the heart's action. He was not so sure, however, that the action on the respiratory functions could be thus explained. They were taught that opium in any form acted on the heart as a stimulant; and it seemed strange that a drug which acted as a stimulant of the vaso-motor and of the vascular systems should be antagonised by another that had a precisely similar action.

Dr. HAWTREY BENSON had the notes of a case of poisoning by belladonna berries, which occurred under his own care about three years ago, which afforded strong presumptive evidence of the antagonistic action of the two drugs.

After some preparatory treatment he put the child on opium, giving him three minims of tincture of opium every two hours. He continued very well under this treatment for thirty hours, and at the end of that time was so far improved that he stopped the treatment. In the meantime he had got eighteen doses, that is to say 54 minims of opium. He thought this was a strong presumptive evidence that opium was antagonistic to belladonna, not merely from the fact that the child recovered, but from the fact that it showed, after taking 54 minims of tincture of opium, no sign of the physiological effects of opium, which he must have done if there were not some strong antagonistic influence at work.

Dr. FINNY, in reply, said the first case mentioned by Dr. M'Swiny was remarkable for the large quantity of opium given after the atropia; but it was given 3½ hours after, which was an objection to the case as an illustration of the theory for which he contended; because Dr. Harvey said that after a period of three hours the usual effects of atropia poisoning were passing off of themselves. The point alluded to by Drs. M'Swiny and Hayden was well known, *viz.*, the long continuance of the dilatation of the pupils. Though the general physiological effects of the two poisons showed they were opposed one to another, the local effect of poisoning by atropia on the pupil was not contracted by the greatest quantity of opium.

THE INCUBATION OF MEASLES.

Mr. TUFFNELL detailed a few facts involving the question of the incubation of measles, or of the starting of the disease *de novo*.

On the 16th of May, last year, a soldier of the 16th regiment was sent up from Enniskillen to the military prison in Dublin. On the 28th of June, the man had the symptoms of an ordinary cold, and was confined to his cell. On the 1st of July, when he (Mr. Tuffnell) entered the prison, he was told the man was ill, and when he saw him he found him covered with measles. He had been forty-five days in the prison, and had had no communication with the external world during that time. He (Mr. Tuffnell) was not attending any other case of measles, no other person in the prison had the disease, the washing was all done within the walls, and yet the man had a genuine attack of measles. Therefore, the case was this—either the period of incubation was forty-five days, or the disease had sprung up *de novo*. He had looked through the various Medical works and journals to find the longest period of incubation recorded, and the longest he could find mentioned was in Dr. Churchill's work on the diseases of children, in which he said the period of incubation could be from ten to thirty days.

Dr. HENRY KENNEDY said he was not aware of any cases of measles where the stage of incubation was as long as the instance given by Mr. Tuffnell, and that for a long period he had held the opinion that measles and allied affections were capable of being generated from within. As bearing on the subject of measles, Dr. Kennedy said he could not but allude to a case published by himself some years since, where a young

gentleman had a handful of mouldy linseed meal thrown in his face at a moment when he was laughing. The effects were very remarkable, for he was at once seized with symptoms of violent corza, attended by swelling of the face, and a dark circle round the eyes, and within thirty-six hours a distant rash like wheals, but of a red colour. The attack lasted three weeks. At the time of its occurrence, Dr. Kennedy was in complete ignorance of its nature; but shortly after his eye was caught by a paper in the *American Journal* by Dr. Salisbury, in which it was proved to demonstration that the fungi of mouldy straw could, by inoculation, generate a disease very like to measles. The writer had not only inoculated himself, but also several others, and in each instance a distinct disease, like measles, was generated, in a period varying from two to three days. This most valuable paper seems not to have attracted the attention to which it is beyond question entitled; for if vegetable fungi thus produce disease, and if the special case already noticed by himself be kept in mind it might well be asked where would such a state of things end? Would not every fungus produce its own disease, and might not every anomalous rash, whether with or without fever, and such were very common, be fairly attributed to some like cause?

Dr. M'SWINEY—Dr. Kennedy said he did not see why typhus fever might not arise spontaneously, and that observation induces me to mention the facts of a case that came under my notice. The hospital with which I am connected does not receive typhus patients, and accordingly we see none there as a rule. Some time ago a strong-looking countryman, who came recommended by a patron of the hospital, was admitted complaining of lumbago. He remained there fifteen or sixteen days, taking his food and apparently in good health, so that it was considered as rather an abuse of the charity to keep him any longer. At the end of the period I have mentioned he was suddenly attacked with typhus fever, and he had to go through it in the hospital, and it was an extremely well pronounced case of the disease. There was no other case of typhus fever in the hospital, and but little intercourse with the external world, and it had all the appearance of a case of typhus fever arising *de novo*. I made every exertion to trace the source of the contagion, but failed to find any.

EPIDEMIOLOGICAL SOCIETY OF LONDON.

JUNE 12TH, 1872.

ROBERT LAWSON, Esq., President, in the Chair.

A PAPER was read by DR. SMART, C.B., R.N., on

ASIATIC CHOLERA IN AFRICA.

Africa, from its geographical features and social conditions, possesses four epidemiological regions:—

- 1st. Egypt and Tripoli.
- 2nd. The Western basin of the Mediterranean, so far as Algeria and Morocco form part of it.
- 3rd. The West Coast, South of the Sahara.
- 4th. The East Coast, from Abyssinia to the Portuguese settlements.

Egypt, next neighbour to Arabia, has not suffered invariably when Arabia has done so. Its visitations have been of short duration. It has on one occasion only been the source of European infection in 1865, and, on the other hand, it would appear to have been infected from Europe in 1854.

Tripoli, although not always involved in the epidemics of Egypt, as in 1847-48 and '54, has had its visitations concurrently with others of that country. Tunis has generally followed on Algeria after a year's interval. In 1859-60 it escaped when Algeria was infected. Egypt was also then untouched, Arabia being infected. The Western basin of the Mediterranean, except in 1835, when it received its infection from Egypt, has participated in the epidemics of Northern Europe, imported into its Atlantic States. But in 1853, and again in 1859, its epidemics are said by some to have had regional origin and growth in the Peninsula. Algeria and Morocco have been always indebted to the European shore for the "contagium" of cholera—the former generally to France, except in 1834 and 1859, when it was so to Spain, and the latter to Spain usually. Morocco was free in 1865, when Spain was severely visited; but this was reversed in 1868—Spain

being then free, and Morocco diseased, having relighted the epidemic that had been present in Algeria in 1866-67; and in Tunis in the latter year. Both Morocco and Tunis had excluded cholera by quarantine in 1865, but they failed later on their land frontiers. The West Coast of Africa was visited for the first and only time in 1868-69, when the disease appears to have been carried from Fez across the Sahara to an upper trading station, on the river Senegal, by caravans. It then extended to the Gambia and Rio Grande, through the inland stations, and was at the same time present in the State of Boradoo—800 miles inland betwixt the water sheds of the Niger and Gambier. The East Coast of Africa, from Abyssinia to the Portuguese settlements, has had a series of epidemics entirely apart from those of Egypt. Abyssinia is in constant communication with Arabia, and during the season of the N.E. Monsoon, from December to March inclusively, Zanzibar has many arrivals from India, the Persian Gulf, and Arabia, from either of which cholera might be conveyed, to be spread from it Southward by means of the native trading craft. The first visitation was in 1836-37, affecting almost exclusively the negro race. It crept along the coast North of Zanzibar, and from that post to the stations South of it, remaining only a few weeks in Zanzibar. The second visitation was in 1856. It was confined to Abyssinia. Arabia had suffered in the two preceding years, and Zanzibar was undergoing a heavy loss by small-pox in the same year. The third visitation fell in 1858-59, whilst Arabia was in an epidemic from Muscat to Djeddah. The disease appeared early in the monsoon in the ports South of Guardafui, and extended to Mozambique with great epidemic force. The fourth visitation of 1865, the year of the last great epidemic that spread into Europe from Arabia, the disease showed itself very early in the year in Abyssinia, and at the fair of Berbera on the South shore of the Gulf of Aden. From this latter place it was conveyed by caravans to the coast of the Indian Ocean; but being late in the monsoon season, it did not extend to Zanzibar. The fifth and last visitation of Zanzibar, in 1869-70, has been traced by Dr. Christie as far as the Galla country, travelling slowly southward among pastoral tribes; it seems not impossible that it may have been conveyed into Africa by the negro pilgrims of Soudan, called "The Takroories," or people of Tocru, which embraces the fertile plains from the Nile to the Niger. This race was the first to suffer from the epidemic in Arabia, and they may have carried it home with them into the centre of Africa, from which it may have extended Westward, to Bonadoo, by the course of the Niger, and Southward by the Nile to the places where the Arab caravans from Zanzibar fell in with it, and took it back with them to that emporium from which it was carried again inland by caravans that followed a more southerly direction, and northward by native craft to Socotra. In 1870 it spread southward as far as Quillimane, and seaward to the Comoro Islands and Madagascar, and from it to Mauritius, an island that had on previous occasions been infected direct from India, or had grown its own epidemics of cholera. A remarkable feature of the epidemics of the East coast of Africa is that they have, with the exception of that in 1865, arisen in the Apogee of the great epidemic cycles when about to cease beyond the limits of Arabia, and not when issuing forth from them, which is strange if we consider its direct intercourse with India. The history of cholera in Africa bears very strong evidence to the theory that its spread is entirely regulated by human intercourse, and timed relatively to the rapidity or slowness of that intercourse, Africa in this respect representing the very antithesis of what is shown where mankind travel by steam power; consuming years in effecting as much as is then completed in months. In the African epidemics, the native negro races have suffered incomparably more severely than the Arabs, Indians, or Europeans present with them. On the Mediterranean shores of Africa there have been repeated instances of the abortive introduction of the "contagium" of cholera, and others where epidemic intensity has speedily followed on apparently trivial importations. In Algeria the outbreaks have always followed a history of importations, and they have been manifested in crowded hospitals, prisons, and barracks, and in camps, and evacuations of these wherever it has been applied to such foci, has been invariably successful in cutting short the epidemic. Ample proofs have been amassed of the efficacy of strict quarantine in excluding cholera on the seaboard, although it has appeared in parts thus temporarily exempted after suspicion had ceased and quarantine relaxed; being introduced by a slower land intercourse.

Hospital Reports.

HOSPITAL FOR DISEASES OF THE THROAT.

Exophthalmic Goitre.

(Under the care of Dr. PROSSER JAMES.)

(Notes by DR. WAGNER.)

MARY ANNE SCRIVENER, *æt.* 38, married, had six children. Not had good health for many years; always feeling weak and languid.

About four years ago first noticed a swelling in the front of the throat, and went to Charing Cross Hospital. Shortly before this her husband had noticed a "staring" in her eyes, and great palpitation of heart. Since that time the throat has enlarged, and palpitations are very distressing; sight not so good. No history of rheumatism. Pulse 140, weak.

Thyroid gland much enlarged, especially right lobe. Eyeballs very prominent. There is a loud systolic bruit at midsternum, level of fifth costal cartilage. The bruit is still louder at fifth costal space directly below nipple, where the heart's apex appears to beat. The slightest pressure on thyroid causes a feeling of suffocation. Sometimes she fears to lie down from an apprehension of suffocation.

This case was examined carefully by several visitors. Dr. Prosser James made some clinical remarks on the case, and compared it with several that had been under his care, going carefully into the usual combination of symptoms. He remarked that no disease more aptly illustrated the need of a possession of a knowledge of all branches of medicine. Many cases were seen at the ophthalmic hospitals on account of the interference with vision; others came here because throat symptoms were prominent from the pressure of the enlarged thyroid, and he had often been consulted for palpitation of the heart when this curious disease existed.

This patient has improved somewhat. She has been treated at present by iodide of iron.

Amongst other interesting points mentioned by Dr. Prosser James may be named that of the history of the disease, cases having been related prior to those of either Graves or Basedow. But as the subject of exophthalmic goitre will be included in the Special Reports commenced in this Journal, it is not necessary to go further into it on this occasion.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 24, 1872.

SANITARY REFORM.

As it seems the Public Health Bill is not to be massaged with the rest of the innocent, we suppose we ought to express some satisfaction, and yet so much has been said against it, that we might find condemnation enough even from its friends.

Perhaps the most encouraging feature of the discussion, has been the willingness of both parties to pay attention to the health of the people, and if the bill must be acknowledged to be imperfect, it is something to get any measure

at all through the House at such a time as we have lately passed through.

Last week we gave some account of the debate. Since then, Mr. Disraeli has spoken upon it in a manner that induces us to quote some of his remarks. His objections having been removed by the recent changes in the bill, he supported it as a good instalment of sanitary reform, in a speech, of which the following is the substance:—

"The merits of this measure are not to be estimated by comparing it with any large and adequate measure of sanitary legislation, consolidating all the existing powers and constructing new ones, which at the commencement of the session, if the Government had made up their mind to direct their principal energy to the treatment of such a measure, no doubt might have been carried. But the question we have to ask ourselves is whether the sanitary legislation of this country will, if this bill passes be more efficient than it is at present. That really is the practical question, and I cannot but believe that every candid man, whatever may be his expectations as to the future treatment of the question of sanitary legislation, or whatever were the hopes in which he may have previously indulged on the subject, must admit that the sanitary condition of this country will be more satisfactory than it is at present if this bill passes. Now, I think, considering the public requirement of the country on this matter, and the strong convictions of those who are most competent to guide public opinion on any important question, we should undertake a very grave responsibility if, under such circumstances, we did not agree to the passing of this measure. The measure as originally proposed would certainly have led to a further and, perhaps, not an inconsiderable increase in the local taxation of the country; and after the vote at which the House had arrived in the earlier part of the session on that subject there would have been such a glaring inconsistency in acceding to a measure which would increase the local taxation without any arrangement on the part of the Government tending to alleviate an increase of taxation, that I myself, strong as are my views as to the absolute importance of this House proceeding with sanitary legislation, should have felt the greatest difficulty in giving my support to the measure of the Government. But the Government have made a proposition which has been considered by those who take a very great interest in the subject of local taxation as being on the whole a fair and reasonable proposition. It has removed the great difficulty I just referred to, and therefore I trust the House will assent to the passing of this measure. I have no doubt that, in considering the machinery which we are about to institute, many details will be found which may be fairly liable to criticism, and many suggestions may be made which may improve the proposition of the Government, or which may even remove such of their proposals as the House may deem objectionable; but the present is not an occasion on which we need enter into these details. What the House has now to do is to declare that it will support the policy of the Government in passing this measure. It is one which is not, in my mind—nor, indeed, is it in the opinion of the Government—adequate to the great subject we shall have ultimately to deal with, but it meets many difficulties that are now encountered, it renders more efficient existing legislation, and it is a preparatory step to the large measure which the Government have announced that they will on the first opportunity introduce.

ARMY HOSPITALS IN AMERICA.

ALTHOUGH somewhat late in the day to give an account of some of the hospitals during the war of Secession, yet it is considered that at the present time when the subject of Medical Administration is on the *tapis*, the following extracts from a report by a gentleman who visited Washington at the time in question, may not be without interest, more especially to our military readers.

The buildings at Washington used as temporary hospitals, in number about 35, are some of the finest and those most suited for the purpose in the city; the Medical and sanitary arrangements were excellent; every adjunct

tending to the health and comfort of the men was adopted ; their wants were sedulously attended to both by the Medical officers and those working under them, and the utmost liberality displayed in meeting all their requirements.

The "Armoury Hospital," so designated from its vicinity to a building of that description, is capable of accommodating 500 patients, its site is in the immediate vicinity of the railway communication with that portion of the country where the troops have been chiefly engaged, it is composed of eleven wards, each being a separate building ; they are arranged parallel to one another and at a distance apart of about 40 or 50 feet, they are erected entirely of wood, their plan of construction similar throughout, one story high with pent roofs, the floors are raised a foot from the ground with open space underneath to admit a free current of air, in length they measure 182 feet, breadth 25 feet, and height 14 feet ; for ventilating purposes there is a small opening on both sides of the edge of the roof extending the entire length, in each side wall are 15 large windows capable of being opened, and in the centre a door communicating by a roofed passage with the adjacent ward, on either side, in the lower part of the walls and under the beds are a number of openings about 10 inches square which can be closed when necessary, at the ends are two large windows with a door intervening ; the extremities of these buildings are partitioned off at one end into two rooms, in one those patients out of bed take their meals, the other is appropriated to the female nurses ; (2), at the opposite end are three compartments, one a sleeping room for the orderlies ; (3), one an ablution room with bath arrangement, the other a water closet. In both of the latter water laid on and floors tile, the remainder of the ward accommodates the patients, fifty in number, the beds are placed along both sides about 2½ or 3 feet apart, the cubic space afforded each man is 1,400 feet ; the beds are of iron with frame tops supporting curtains of fine white gauze for keeping off flies, &c., the mattresses are composed of hay with the usual covering of sheets, blankets, rugs, and pillows, &c., beside each bed is a chair and table, with utensils of delf. At the head of every bed is recorded the letter distinguishing the ward, number of bed, name of occupant, nature of injury or disease, with the daily treatment, and articles of diet shown in numerals. Those beds which contained patients with more formidable injuries are marked by a small coloured flag fixed to the foot rail. Through the centre of each ward between the beds thick matting extends the whole length, which, in addition to aiding towards cleanliness, adds much to the comfort of the sick in preventing noise being caused by passers through.

One of the wards is occupied differently to those (ten in number) just described, in its external appearance it resembles them, it is divided into a number of compartments, which comprise quarters for the assistant-surgeons, Medical cadets, Medical officers' mess, surgery, dispensary, store rooms for medicines, comforts, linen, and bedding, &c., private office for Medical officer in charge, also a large room for general purposes in which the Medical officer on duty remains during his turn ; one corner of this room contains a post-office. All the wards have a deep drain cut round them and the whole are enclosed by a neat wooden fence, together with the outbuildings pertaining thereto,—viz., a cook house on a very extensive scale with appliances for boiling, baking, and roasting, laundry with

drying room attached, pack store, general store, guard house, dead house, &c.

The atmosphere of the hospital, every bed full, is cool and pure. Chlorides are freely used in the waterclosets and urinals. Strict discipline is maintained among all. Both patients and their beds presented a most tidy and cleanly appearance. Religious books, periodicals and medicines in use are only sanctioned in the wards. As well as I recollect I was informed no cases of erysipelas or hospital gangrene had occurred, and pyæmia had been extremely rare.

Medical Staff and Attendants.—The entire management and control is invested in a Medical Inspector, under him are 10 Assistant-Surgeons (1 for each ward), Medical Cadets, 1 Head Ward Master, 10 Assistant Ward Masters (1 for each ward), 3 Assistant-Stewards, 30 orderlies (3 for each ward), and 20 female nurses (2 for each ward).

Respective Duties.—The Medical Inspector visits the hospital every morning, receives written daily reports from the Orderly Medical Officer, sees bad cases under the charge of the Assistant-Surgeons, examines returns, accounts, attends to correspondence, signs passes, &c. On Sunday morning he inspects all the wards, bath rooms, water closets, outbuildings, hospital drains, grounds, &c., and notifies their condition as "perfect," or otherwise. The Assistant-Surgeons reside and have their meals in the hospital, visit their wards at 7 o'clock a.m. and 6 o'clock p.m. by bugle call, act as Orderly Medical Officer by turn, whose duty is to attend anything required in the wards, to visit the guard at stated hours, day or night, to go round the wards during the meals and report complaints, to order diet for the following day for all patients out of bed, "table patients," and hospital attendants, and to register the same in a book in order to ensure variety. This being always referred to previously, furnishes a "morning report" to the Medical Inspector. Medical Cadets act as dressers in their respective wards. Head Ward Master has charge of all the stores, comforts, linen, bedding, pack, &c., keeps accounts of each, and overlooks Assistant Ward Masters in their duties. One Assistant Ward Master has charge of bedding and linen, furniture, of each ward, cleanliness, &c., and is under the orders of the Head Ward Master. Three orderlies to each ward ; these act under the Assistant Ward Master, they wait on the sick and maintain order and cleanliness, &c. Two female nurses also attend to the wants of the sick of each ward, administer medicine, linen, &c. ; one accompanies the Assistant-Surgeon round at morning visit and notes the diets prescribed, each article being distinguished by a numeral as shown on accompanying scale. Three stewards ; two are fully qualified dispensers of medicines and act as such, the other attends to the dieting and purchases articles as they are required. Cooks prepare lists of the different articles required for the diets from the female nurses, and these are examined by the Medical Inspector. Washing is done by "contrabands" in the hospital enclosure ; the grounds and drains, &c., are also kept clean by them.

Diets.—There are no formulæ of diets for hospital purposes laid down, the articles prescribed are left entirely to the discretion of the Medical officers. At the "Armoury Hospital" the plan adopted was, the patients were divided into two classes ; one included those out of bed, called "table patients," the other those unable to leave their beds. Each was dieted differently ; for the "table

patients" and attendants the ordinary soldiers' rations were drawn from the "Subsistence Department," the lists being prepared daily by the Orderly Medical Officer; for those in bed a "Numerical Diet Table" was prepared of all those articles most likely to be required, many of them being contained in store. From this table, in order to ensure variety, four separate lists were formed, each containing separate and appropriate ingredients for the various meals. From one of these lists articles of diet were selected for Mondays and Tuesdays, from another for Wednesdays and Thursdays, and so on for those so dieted and not drawing rations. Commutation of 18 cents per diem was granted, and which formed a fund for defraying the expense of those articles included in the list and not contained in store.

The gentleman from whose report we quote, thus continues:—

"The soldiers generally presented a robust appearance, though some were mere lads; they seemed to be well clothed and fed, and possessed of a fair amount of physical endurance. I saw some regiments pass through Washington, said to have marched seventeen miles, they appeared not fatigued and had no stragglers, they were in heavy marching order, packs supported by shoulder straps, leaving the chest free, their blankets were in a roll and carried across the left shoulder. I did not observe a single case of drunkenness among the men either at Washington or on the Potomac; the sale of spirits was completely suppressed, neither malt nor spirit formed part of the rations, coffee being issued instead. This arrangement was not departed from either on going into or after action; the men seemed invariably orderly and well-behaved."

Notes on Current Topics.

An Important Medico-Legal Decision.

JOHN HAMILTON, a notorious London quack, who was convicted some few weeks since, at the instance of Mr. Henry Chandler, for falsely using the title of "Doctor," and who has appealed through his solicitor to the Court of Queen's Bench, to quash that conviction, was on Friday last again summoned before the magistrate at Marlborough Street court by Mr. Deakin, house-surgeon to the Lock Hospital for a like offence. When the case was called, the prosecutor was unfortunately absent, and so the defendant's solicitor had it all his own way. Of course the summons was dismissed, but the most curious part of the affair was, the utter perversion of the opinions so frequently expressed by the Medical journals, upon the use of the title of "Doctor." The legal Profession is fond of a chuckle at the expense of the Medical, but in the present instance the scales are unquestionably turned, and the difference of opinion of the two judges is a very serious matter for reflection. About a fortnight since, Mr. Knox convicted this man Hamilton, "for that he fraudulently misled the public, by falsely calling himself, and using the title of 'Doctor,' to which a sham American diploma in his possession did not entitle him." On the other hand, Mr. Mansfield ruled on Friday, "that a person might call himself a doctor the same as a captain, if he pleased." The defendant's solicitor further stated, that the Medical press was totally opposed to the view taken by Mr. Knox, and in favour of that held by Mr. Mansfield. Now, this is

absolutely at variance with facts. The whole Medical press has never expressed such an opinion, it has been, and must be in the interests of the Profession and the public against fraud and imposition, when palmed off upon ignorant and unsuspecting victims, by diplomas which no more, either legally or morally, entitle their holders to pass themselves off as Medical men, than does the manufacture of base coin, because it is a good imitation of the real thing, exempt the coiner from a situation for a long term of years in one of Her Majesty's prisons. Mr. Ricketts, the defendant's solicitor, may take this as our opinion gratuitously: that one is just as much a swindle as the other, and that as the coiner touches only the pockets of his victims, and the quack doctor, both the body and the pockets, so the latter's punishment should be proportionately greater.

Electro-Therapeutical Apparatus.

At a recent meeting of the Boston Society of Medical Sciences Dr. Lincoln exhibited the electro-therapeutical apparatus of Brenner, consisting of a mahogany tablet thirty inches square, upon which are arranged the following instruments:—

1. "Current-selector" or switch-board, for introducing into the circuit any number of elements, up to sixty. Brenner himself prefers the use of pegs to that of the switch, but they are more troublesome to handle.

2. "Upright tangent-galvanometer," the wire of which measures 0.008 inch in diameter and offers 82.4 B. A. of resistance.

3. "Commutator," for instantly reversing the direction of a current, whether galvanic or Faradic, without changing the position of the electrodes in reference to the body.

4. "Rheostat," forming a portion of an accessory circuit. It contains 2,100 units of resistance (Siemens, = 200.7 B. A. units), and as these are arranged by tens, the instrument enables us to measure 210 grades in the intensity of the current, whether generated by one cell or several. Brenner attaches great importance to its use in treating the auditory nerve, as by it we are enabled to begin with a very minute fractional dose of electricity and to raise the quantity by degrees, so as to avoid the infliction of a sudden shock, which might prove a serious injury.

5. "Rheotome." This instrument acts in two ways, depending on the arrangement of certain pegs connected with it. In the first place, when a constant current is flowing, it can produce a single momentary interruption; in the second place, the current not flowing, it can produce a single momentary passage of the current; and the shock—from the interruption, or from the passage of a current, as the case may be—can be made to last a longer or shorter time by sliding a metal plate in or out. The instrument is essentially composed of a finger of brass, swinging horizontally upon a pivot, and its course impinging upon the plate of metal just mentioned—the current enters at the pivot—and is conveyed through the brass finger to the metal plate during the moment of contact.

6. "Automatic interruption of the constant current." This consists of a "Neef's hammer," similar to those attached to the electric alarm-bell. The rate of rapidity with which interruptions can be effected varies from four to ten in the second, which is sufficient for practical use. The indicator of the galvanometer, which during the passage of the uninterrupted current would mark 35°, points to the neighbourhood of 15° and 20° when the current is interrupted by this apparatus; showing that a great quantity of the current still passes.

7. Du Bois-Raymond's "sledge apparatus" for generating the Faradic current. The primary coil contains about 320 turns of wire, the secondary 9,970. The teta-

nizing effects of the current from the primary coil seems greater than that from the secondary; its *quantity* is distinctly apparent in the deflection of the galvanometer-needle to the extent of nearly one degree. The secondary coil gives a spark of a tenth of an inch only, its construction not being suited for the development of the enormous tension which some of Mr. Ritchie's coils display.

The hammer is made in two pieces, the inner of which may be drawn out like a telescope slide for the purpose of retarding the rate of vibration. By weighting it with two or three small copper coins it may be retarded still farther, giving as few as four strokes in the second: the extreme rate of rapidity being indicated by the production of the musical note F , proving that 168 interruptions per second are effected.

The motive power of this Faradic apparatus is furnished by two Leclanché elements; the galvanic current is obtained from sixty Daniell's cells, as modified by Siemens and Halske.

The Leclanché element consists of a cylinder of zinc immersed in a solution of sal ammoniac, and a piece of carbon packed with powdered binoxide of manganese and carbon in a porous cell. The cheapness of the exciting fluid—for only one fluid is required—is a recommendation of this form of battery; it is said also to be very constant, and it certainly makes very little trouble or dirt. It generates ammonia gas when in action, which would be an objection to the use of a large number of cells in an occupied room.

The Siemens-Halske element cannot well be described without a diagram. It is a very constant element and requires little attention. The metal and fluids are the same as in an ordinary Daniell's cell, but the diaphragm (of porous clay) is reinforced by a layer of papier-maché some inches thick, which increases the resistance very much.

The arrangement of switches in the apparatus is such that three patients can be operated upon at once, one receiving the current from the primary coil, another that from the secondary, and a third the galvanic current.

The apparatus deserves especial praise for the solidity with which all connections are made, and the accuracy with which the switches are adjusted, and the pegs fitted. The only instrument liable to be injured by careless usage is the Faradic apparatus, especially the hammer; it would not be a proper thing to entrust to the management of a nurse; but it is capable of producing a great range of effects, and its currents are very smooth and equable.

Krüger and Hirschman, of Berlin, constructed the apparatus.

In answer to a question from Dr. Bowditch, Dr. Lincoln said that the papier-maché served the purpose—First, in keeping the zinc and copper at a fixed distance from each other; and second, in offering a great *resistance*, which increases the penetrating force of the current. In passing from the zinc to the copper, the current had to traverse two inches of the densely-packed papier-maché besides the earthen diaphragm.

Alcohol as a Nutritive Agent.

We find in the new number of the *Boston Medical and Surgical Journal* a paper on this subject, read before the Boston Society of Medical Sciences, by Dr. H. P. Bowditch, in which he observes that the experiments of Dr. Subbotin were performed on rabbits enclosed in an apparatus by means of which the exhalations of the skin and lungs could be examined for alcohol. The urine was also collected and examined for the same substance.

The experiments showed that in the first five hours after the introduction of 3.45 grammes of alcohol into the stomach of a rabbit, about 2 per cent. was eliminated by the kidneys, and 4 per cent. by the lungs and skin.

Experiments extending over a greater length of time led

to the conclusion that, usually, during twenty-four hours at least 16 per cent. of the injected alcohol leaves the body in an unchanged condition (or perhaps as aldehyde), and that besides this elimination by lungs, skin and kidney, a portion of the alcohol is oxidized in the organism. Although by this oxidation force must be set free in the organism, the author does not consider that alcohol is on that account to be regarded as a nutriment, for the functions of the animal body depend for their performance, according to Dr. S., upon the transformation of living material, *i.e.*, of the constituent parts of the body, and not upon the decomposition of matter foreign to the body.

In a note appended to Dr. Subbotin's essay, Prof. Voit expresses himself as follows: "I do not agree entirely with Dr. Subbotin in his views on the importance of alcohol as a nutriment. I define a nutriment as a substance which is capable of furnishing to the body any of its necessary constituents or of preventing the removal of such constituents from the body. To the first class belong such substances as albumen (since it can be deposited as such in the body), or fat or water or the mineral constituents of the body; to the second class belong such substances as starch, which hinders the loss of fat from the body. If a nutriment is defined as a substance which by decomposition furnishes living force to the body, the definition would not be exhaustive, for it would exclude water and the mineral constituents of the body. Alcohol must, therefore, to a certain extent, be regarded as a nutriment, since, under its influence, fewer substances are decomposed in the body. It plays in this respect a similar (though quantitatively very different) part to that of starch, which also protects fat from decomposition and, when taken in excess, causes deposition of fat in the organs or fatty degeneration. If a part of the alcohol is decomposed in the body into lower forms of chemical combination it *must* give rise to living force, which either benefits the body in the form of heat or may perhaps be used for the performance of mechanical work; the same is true of acetic acid, which is also not to be considered as an ultimate excretory product, and from which, therefore, in decomposition potential force passes into living force.

"It is another question, however, when we ask what importance alcohol has for us as a nutriment, and whether we take it in order to save fat from decomposition and furnish us with living force, in other words, to introduce a nutriment into the body. Since alcohol, when taken in considerable amount, causes disturbances in the processes of the animal economy, we cannot introduce it in quantities sufficient for nourishment as we do other nutriments, and in the amount which we can take without injury its importance as a nutriment is too small to be considered. In this point, then, I agree entirely with Dr. Subbotin; we use alcohol not on account of its importance as a nutriment, but on account of its effects as a stimulant or relish."

Prof. Voit's definition of a nutriment is rather more comprehensive than those usually given, but it has the merit of great exactness, and of leaving no doubt as to its applicability to any given substance. Whether this definition or any other be adopted, it is, of course, essential, as a preliminary to the discussion of the nutritive value of alcohol or any other substance, that we should define as exactly as possible what we understand by the terms "nutriment" and "nutrition."

Although, as Prof. Voit says, alcohol cannot, under normal circumstances, be introduced into the body in sufficient amount to be of any importance as a nutriment without producing toxic effects, may it not be that in those morbid conditions of the system where large amounts of alcohol are borne without causing narcotism, the nutritive properties of the substance really become important, and that patients who are supported by alcohol through periods of great weakness or exhaustion are really nourished and not simply stimulated by it?

Dr. P. A. SIMPSON has been elected Professor of Medical Jurisprudence in the University of Glasgow.

The Small-Pox Epidemic in Canada.

DR. ALLISON contributes to the last issue of the *Canada Medical Journal* a statistical statement of the recent severe inroad of small-pox in that territory. The cases, so far as made known to the Board of Health, were 205 in all: 98 males and 107 females. Of these, 32 males and 39 females died; 71 in all, or nearly 34 per cent. of the whole number attacked. This heavy mortality was chiefly due to three circumstances, each of which claims a word or two for itself. 1st. The neglect of vaccination; 2nd. The large proportion of those who were attacked during the early months of life; and 3rd. The great malignity which has everywhere characterised the epidemic of 1871. Of 138 unvaccinated people who took the disease here last year, only one escaped with a varioloid attack, and 69, or just half of them, died; 25, or not far from half of these, again, had either hæmorrhagic small-pox, which is invariably or speedily fatal, or the petechial form, which, though a little more protracted in duration, is hardly less deadly. All the rest, except some eight or nine, had confluent or copious eruptions, which, even in epidemics of the ordinary type, prove fatal to a full third of those who exhibit them. On the other hand, 67 vaccinated people took the disease, and 30, or nearly half of them, got off with varioloid attacks. Only two of them died, or about 3 per cent., which is just the usual mortality of small-pox after vaccination. This furnishes us with an important addition to the argument in favour of vaccination, which I have not found dwelt upon as strongly as it deserves to be by any of our authorities, *i.e.*, that the malignity of the epidemic does not raise the percentage of mortality amongst the vaccinated. While the mortality from the natural disease, never lower than 12 or 15 per cent., may be swelled to 50 per cent., and upwards, by an increase of malignity in the type of the epidemic, small-pox after vaccination, is, on the contrary, an uniformly mild disease, and attended with an uniformly low rate of mortality, whatever the type of the epidemic may be. The malignity of the epidemic has been noted during the last two years in every locality where the epidemic has shown itself. It is evinced in the large number of hæmorrhagic and petechial cases, both of which are usually great rarities. Twenty-six, or more than a third, of these cases, died before the fifth day, only one lived beyond the nineteenth, and the average duration of the whole 71 cases was but seven days and a fraction.

The St. Bartholomew's Convalescent Home.

DR. FORSHALL, of Highgate, has been appointed visiting Medical officer to the new Convalescent Hospital, in connection with St. Bartholomew's Hospital.

The Looshai Expedition.

THIS expedition has now come to a close, the despatches describing its incidents and successes have been published, and a very fair share of credit and praise accorded all round to the officers. The Medical department has, the *Indian Medical Gazette* observes, not been forgotten. How largely the success of the expedition depended on Medical arrangements and officers, those who know its circumstances best can best testify. Deputy Inspector-General of Hospitals H. B. Buckle, C.B., has been highly complimented, and most deservedly, for his indefatigable exertions and judicious arrangements. Surgeon-Major F. F. Allen, of the 2nd Goorkhas, who was administrative

Medical officer of the right column, performed his share of the work most admirably, and most of the executive Medical officers who served with the expedition have been commended in the despatches for their zeal and willing exertions. Surgeon J. B. White, of the 42nd Assam Light Infantry, especially distinguished himself by the able manner in which he dealt with a serious outbreak of cholera among the Nepalese coolies. The general principle of the Medical arrangements, as described in the papers, contributed by Drs. Smith and Harvey, which we have recently published, was to provide a series of general hospitals in rear of the advancing columns to which the sick and incapable should be promptly carried for treatment.

Australian Meat.

THE *Cork Examiner* mentions the result of some trials of Australian meat undertaken by the Cork Board of Guardians, which appears to be highly favourable to its use as a substitute for fresh meat. On Sunday last the foreign meat was used in making soup for 136 children, and while the quality of the soup was quite satisfactory to the physicians, the saving effected was very considerable. From figures submitted by Dr. Wherland, it appeared that the cost of one meal of fresh meat to 416 patients was £1 18s. 1d., and by using Australian meat £1 11s. 6d., thus effecting a saving by the use of Australian meat of 6s. 6d., or about 18 per cent.; and by utilising the tins at the rate of 2d. each, there would be a saving of 9s., or about 21 per cent. The fresh meat for the children's soup cost for one meal £1 8s. 10d., while the Australian meat only cost £1 1s.; the use of the latter causing a saving in one meal of 27½ per cent., or by utilising the tins of 31 per cent. To make assurance doubly sure, the Board has resolved to continue the trials for another fortnight.

Adulteration of Food, Drugs, &c., Bill.

THIS Bill, which has already been printed, is set down for Committee on Thursday, July 11th. Lord Eustace Cecil has given notice of amendments in Clauses 4 and 5 that would have the effect of making compulsory the appointment of analysts and the duties of inspectors in procuring samples of suspected articles for analysis. He also proposes to add the following definition of adulteration:—

“The word ‘adulteration’ shall mean—

“1. The admixture of any mineral substance (excepting the harmless compounds of potash, soda, and ammonia) with any article of food or drink.

“2. The admixture of anything with an article of food or drink for the purpose of increasing its bulk or altering its natural strength or flavour, unless such admixture is declared by the dealer or vendor to the purchaser at the time of sale, or unless such admixture is clearly set forth in a label upon the article.”

The Cholera in Oude.

THE *Pioneer* gives the following figures, which fix approximately the mortality in Oude from cholera during the present year. To the 5th of May 7,456 persons had been attacked, and 5,221 had died. During the succeeding week 417 persons were attacked, and 288 died. The total, therefore, of cases up to the 12th was 7,873, and of deaths 5,509.

Doctors and Ladies' Dress.

SOME of our contemporaries are quoting with horror a statement in the *Swiss Times* that "several of our future 'doctoresses' are adopting costumes which are neither male nor female. They wear short dresses, their hair not so long as many of the students of the opposite sex, small round hats, &c. In a word, their whole appearance confirms the opinion that if a young girl wishes to study medicine she must cease to be a woman. In short, she must be, 'as was said of Queen Elizabeth of England, 'more than a woman, and less than a man.'" Why not? If the lady doctors should succeed in introducing comfort and common sense into the dress of either sex they will have done something for which we ought to be grateful. We groan this hot weather under chimney-pot hats and black-cloth coats. While ladies' dress in England is neither healthful, nor indeed at times, quite decent, a sort of compromise would be good for both sexes. And as to trousers being unfeminine, the ladies wear them on horseback, and they are certainly more delicate than what are called low neck dresses, but which retire to such a distance from the neck that it is quite a misnomer. We prefer half-masculine covering to no covering at all, both in the sense of health and modesty.

The Sanitary Condition of Edinburgh.

LORD KINNAIRD, in moving in the House of Lords for the return submitted to the Town Council of Edinburgh by the burgh engineer, stated that it gave a most alarming account of the sanitary state of that city, and it was a fact that the death rate in Edinburgh had increased so considerably that the insurance companies were contemplating the raising of their rate of insurance. Perhaps some of the companies will be prepared to take up the neglected risks, but the Scotch companies we fancy are too canny to let them go.

Italian Medical Journals.

WE beg leave to call the attention of English Medical men to the very great progress made of late years in Italy in all that relates to the sciences and art of medicine. Italy bids fair again to renew the days when her medical schools were resorted to by the Harveys, the Lockes, and other Medical men of renown. Let such as doubt this read the *Revista Clinica* of Bologna, the *Indipendente* of Turin, the *Ippocratico* or the *Sperimentale* of Florence, the *Venetian Journal of Med. Science*, and many others, and they will be ready to concur with us. Many of the Italian editors are well acquainted with all that goes on in England, can speak English and French well, and translate both languages with facility. Dr. Eugenio Rey, of the *Indipendente*, has contributed some valuable translations. His version of Dr. Tilt's "Change of Life" was recently mentioned in this journal, from which he has also translated Dr. Prosser James's articles on *Ozæna*, and *Syphilitic Diseases of the Throat*. The new number of the *Indipendente* also contains from his pen a criticism of Dr. C. R. Drysdale's new work on *Syphilis*, which cannot but gratify the author. We take the following words from Dr. Rey's review:—"Speriamo perciò che molti nostri compatrioti intraprenderanno la lettura di questo utilissimo libro."

Dr. G. H. SAVAGE has been elected Assistant Medical Officer to Bethlem Hospital.

Two Aspects of the Siege of Paris.

THE *Lyon Médicale* contains some valuable statistics from a work by M. Sueur on the Siege of Paris. Taking the population of the capital before that event at 1,900,000, it increased to 2,000,000 during the Prussian siege. From the 4th September, 1870, to 18th March, 1871, the deaths numbered 78,000, against 25,000 in the corresponding period under ordinary circumstances. Children, among whom the deaths in the same six months were 7,500, gain now 19,000, cold, want of care, and especially inanition, being the chief causes of the difference. Old people, that is, those beyond sixty years of age, died in great numbers, especially towards the end of the siege; those between the ages of forty and sixty appeared to resist the best, while the men between fifteen and forty years, and particularly those of fifteen to twenty-five, furnished the greatest death-rate, it being in the latter class six times its usual figure, nor was the increase caused so much by wounds as by disease, the young men being the most exposed to cold and fatigue, while their powers of resistance were less than in their elders. Typhus fever, so common in armies and during other sieges, did not appear, for the reason that, although the population suffered from insufficient food, there was no over-crowding. Dysentery was of comparatively mild form; diarrhœa was more frequent, arising from the combined effects of cold, insufficient food, and the inferior quality of what was to be obtained. Two affections followed a steady increase as the siege lasted, namely, typhoid fever and pneumonia, without apparent reference to temperature, while, on the contrary, the curve in the line of prevalence of small-pox and bronchitis followed that of the temperature. During the same eventful period, the conceptions as indicated by the subsequent occurrence of births and abortions descended to less than half their usual ratio, the causes of this being inanition, fatigue during the day, night duty on guard, the number of men constantly in the advanced posts, the decrease in the number of marriages, and the moral unrest of the people, the bare enumeration giving us a somewhat strange insight into the train of thought and social state of our erratic and gallant neighbours. "But," according to M. Sueur, "like the rainbow after the storm, so the armistice proclaimed the return of nature—*La courbe amoureuse est reconite*," en février et mars, "d'un bond à ses hauteurs premières."

Increase of Salary.

THE Guardians of the Edenderry Union, at a special meeting held on the 29th of June, unanimously voted an increase of £20 per annum to the salary of Dr. Saunderson, Medical Officer of Edenderry Dispensary. The Commissioners sanctioned the increase.

Mad Literature.

A NUMBER of our contemporaries seem to have been surprised at the appearance of "Loose Leaves," an elegantly got up little periodical, produced in the Church Stretton Lunatic Asylum. Mr. Hyslop, the Proprietor, deserves credit as the first in England to adopt an amusement and occupation that has elsewhere been such a success. Medical men will, of course, not be at all surprised to find the periodical well conducted, nor will they look in it, as some lay editors seem to have done, for indications of the insanity of the writers. Should

anyone doubt this let him read the "Portrait of a Gentleman" by "One who is thought Insane," and who, despite this article, very likely is. But the gem of this little periodical is "The True Method of Extracting Sunbeams from Cucumbers," which might pass anywhere as a capital satire on certain pseudo-scientific processes.

DR. SHEPHERD has been appointed Assistant-Physician, and Dr. Wiltshire Assistant Obstetric Physician, to St. Mary's Hospital.

THE *German Pharmacopœia* has just been published in Berlin, and is to come into use throughout the German Empire on November 1st.

THE *Société Française de Secours aux Blessés* has presented its bronze cross and diploma to Mr. J. B. Walker, of Clifton Gardens, Bayswater, for services rendered in the ambulances of Beaumont, Saarbruck, and Metz.

WE understand that Inspector-General of Hospitals, R. Dane, M.D., will shortly be given a distinguished service reward after thirty-four years' full pay. He was promoted to the rank of Inspector-General in March, 1869.

A COMPETITIVE examination for the admission of Assistant-Surgeons into the Royal Navy will take place at the University of London, Burlington-gardens, on Monday the 12th of August, and following days, at 10 o'clock.

DR. RAWDON MACNAMARA, of Dublin, continues to make, we are happy to learn, steady but slow progress towards convalescence. He is still resident at Howth, and is under the care of Dr. Stokes.

THE Annual General Meeting of the Medico-Psychological Association will be held at Edinburgh on Wednesday, July 31st, Sir James Coxe, M.D., Commissioner in Lunacy for Scotland, President, in the chair.

THE Mahometan Nawab of Rampoore has presented to the Bareilly Mission a large building for the purpose of a Medical school. Several women have already commenced a scientific course of instruction.

A COMPETITIVE examination for the admission of assistant-surgeons into the Royal Navy will take place at the University of London, Burlington Gardens, on Monday, 12th August, 1872, and following days, at 10 o'clock.

THE President of the meeting at Birmingham will be Alfred Baker, Esq., F.R.C.S., Senior Surgeon to the General Hospital. An error as to the President crept into our last issue.

THE meeting of the International Ophthalmological Congress will be held at the Royal College of Physicians, Pall Mall, on August 1st, 2nd, and 3rd. A preliminary meeting will take place at the College on Wednesday evening, July 31st, at 8 p.m. The meetings will be open to any member of the Profession. Tickets of admission (including the Reports) will be 12s. 6d.; for the meetings only, 8s. 6d. On Saturday there will be a grand banquet at the Crystal Palace at 6 p.m. Tickets, £1 1s.

AT an inquest last week Dr. Lankester said sixty children died the previous week from diarrhoea. He attributed the greater part of this mortality to the influence of the recent heavy thunderstorms upon milk, which was extensively consumed by infants.

WE are informed that the Medical Council has applied to the government for a site on which to build a temple dedicated, we presume, to the wind. We suggest that the Council should be housed in a portable iron house, and a contract made with the builder to take back the edifice when, a year or two hence, the Council shall be reformed out of existence.

MR. C. READ has given notice, in the House of Commons, that in consequence of the unsatisfactory working of the Act, he should, early next session, move for the appointment of a select committee to inquire into the operation of the Contagious Diseases (Animals) Act, and the constitution of the veterinary department of the Privy Council.

AT the Professional Examination now going on at the Faculty of Medicine at Paris, two ladies were candidates. Miss Archer passed well the "1^{er} Examen de fin d'année," and Mrs. Chaplin Ayrton passed well the "2^e Examen de fin d'année." The Faculty having, with their usual courteous liberality to foreigners, accepted the latter lady's certificate of study from Apothecaries' Hall and the University of Edinburgh as equivalent to the Baccalauréat and 1^{er} Examen de fin d'année examinations.

ONE of the latest deaths from chloroform has occurred under the hands of Professor Billroth, and has become the subject of an action at law. It was the occasion of critical reflections in the *Gazette Medicale de Vienne*. Reviewing all the unsuccessful operations of this celebrated surgeon, it remarks that an exactly similar casualty took place under his care in a similar case, of which he took no notice; that another chloroform death took place during his examination of a wounded finger; that, on another occasion, he tied the lingual vein instead of the artery; perforated the bladder in a lithotomy operation, &c., &c. The Journal remarks that if such errors occurred in the case of a provincial practitioner, imprisonment would be the result.

Professor Billroth has instituted an action for libel in order to vindicate his professional character.

Foreign Medical Literature.

UNITED TWINS,

Union of the two Heads by the Occipital Bones, completed on the Right by an Extra Bone common to both Occipitals, and to which I shall give the Name of third Parietal of the Right Side.

By DR. GINE.

(Translated from the *Independencia Medica* for the MEDICAL PRESS AND CIRCULAR, by Dr. AMADEO.)

ON the 29th of August of this year, at half-past ten in the night, I was called to give assistance to Teresa Gimener

de Dalmau, 22 years of age, married and primipara, who had been many hours in labour. Proceeding to the examination, I found the presentation of a foot, which organ was pretty cold, indicating the long duration of the labour. I proceeded to place the woman in the most convenient position, and taking a place before her, commenced the manipulations, and without any difficulty extracted the other foot, and afterwards both arms. In this state I was acting with great caution to bring down the head, and as I could feel the chin I predicted the termination of the labour. But it was not so, because if it is true that the head was descending slowly, and that the greater part of the face was already out of the vulva, there were still some clear indications of an obstacle in the way preventing the full termination of the process.

During the slight traction that I made I endeavoured to place the head of the child in a manner that the occipito-frontal diameter would correspond to the oblique of the mother, and I easily succeeded in this, but the resistance was still the same. Without saying anything to the family in presence of the difficulty, and as I could not cease the manipulations in the state in which the labour was, I suspected a monstrosity, but not the one that I found afterwards. With slight movements of rotation and slight tractions, and by placing the fœtus in the horizontal position and using it as a lever, I noted that the resistance gave way, and I terminated the labour. Then I saw with great surprise that instead of one fœtus there were two, being united by the head in the way seen in the adjoining diagram, and into the description of which I shall enter.

I cut both umbilical cords without ligating them, seeing that the fetuses were dead, although only a few days. I extracted the placenta, and that was attended with no difficulty. There was only one placenta, the cords proceeding near its borders (two centimetres), as I shall show hereafter.

At eleven o'clock the woman was in bed without any accident, and the puerperal state so happy that on the fourteenth day she was out of doors.

Although dead, neither fœtus showed any signs of putrefaction; they were of full term, as indicated by the good conformation, the complete formation of the nails, and other signs; and although they were not of the largest size, they presented sufficient regularity of development.

No other anomaly was exhibited, except the union of the two heads, and in an inverted position.

My wishes were to preserve them, but there was opposition on the part of the parents that prevented me. They only allowed me to take the adjoining drawing.

The monstrosity was only in the head, and consisted in the following:—Both fetuses exhibited the sagittal and parietal sutures well marked, and the union was in the middle and left part of both occipitals, and for prolonging the union in the same side there was an extra bone common to both occipitals, that might be considered as a third irregular parietal. In the right side a depression shows the separation between both heads.

The day following they allowed me to separate the fetuses, and, acting with care, I proceeded to incise the integuments that were common to both in all the circumference, and as the union of the bones was strong, with great care I used the costotome without destroying any part with this instrument. After having cut the bones, I proceed to investigate the condition of the cephalic membranes, each fetus having its own, except in the point of union where they were common to both. To my regret they would not allow me to proceed any further with my investigations, but it seems to me that the cephalic masses were of good conformation, and entirely separated the right from the left side. The orifice that remains in both skulls was of six centimetres in all directions, and almost of circular forms. As I said before, there was only one placenta, the umbilical cords proceeding from its border and being diametrically opposed; from the cords the main blood-vessels start, diminishing in size as they converge to the centre, until they get lost in it.

I shall say nothing here in regard to the classification of the union of the two fetuses, neither what could be the position in the uterus, as I did not observe any deformity that would indicate this.

I must add that the moveability of the bones in both heads over the respective sutures, was a great help for the happy termination of the labour, as this circumstance allows the diminution of the cephalic diameters.

Another Spanish physician, Don Pedro Salvador, writing the clinical history of the case remarks as follows:—

That the monstrosity in question belongs to the monstrosity that Geoffrey Saint Hilaire called "*Simplex Autostiticus*." In fact, each fetus enjoys an independent life, and does not offer in itself the least anomaly. The essentially teratologic, consisted in the fusion of both heads in the parietal regions. Although the observer said that the union was effected by the presence of an extra-parietal bone, we do not see this fact well proved, inasmuch as the section in the point of adhesion produced a hole in the head of one of the two fetuses through which the membranes protruded. For this reason we are inclined to think that, far from there being three parietals, only one existed common to both individuals, and in this way, instead of being a monstrosity by excess, it was by deficiency.

In other respects, the facts of *diplo-genesis* with adhesions are not rare in the science of medicine, one of the most remarkable, being that of the Hungarian girls, Elena and Pudit, whose history is given by Buffon; they had a common anus, and felt simultaneously the desire of going to stool, each girl had an urethra, and felt individually the desire to pass water. Pudit, that was the smallest crooked, had hemiplegia at the age of six, Elena remaining in good health. In opposition to that, both suffered simultaneously from measles. Their constitution was very different, Elena enjoying habitually good health, Pudit living always suffering and weak, until twenty years of age, when she had an attack of typhoid fever that caused the almost sudden death of Elena.

As a most recent fact of history, we may mention the Siamese brothers, of whom the *MEDICAL PRESS* has spoken, and which were the subject of curious debates in consequence of their separation by surgical means having been proposed.

All these cases have reference to adherences from some of the regions of the body, but we do not know of any by fusion of the heads, in which life has continued when once out of the uterus, for which reason, we think

that such monstrosity must be considered as a condition of no viability for both fœtuses.

The clinical observations relating to monstrosity would be all wanting in interest if we had to say of them, that they were aberrations of nature, we do not endeavour to find the causes that give origin to them, and the mechanism by which they are produced. This study is essentially of physiological importance, because it may lead to the illustration of many points little known in the intra-uterine development. Let us proceed to investigate the etiology of the precedent cases, but before doing this, it is necessary to take into consideration the theories emitted in regard to these anomalies of the organisation. The ancients allow a transcendental influence to the imagination of the mother, and still to day many vulgar people believe in this. Everyone knows the artifice employed by Jacob in order to obtain many spotted and speckled goats, which, according to agreement with his step-father Laban, ought to belong to Jacob. One princess accused of adultery, because she gave birth to a black child, was absolved by Hippocrates declaring that this fact was duo to the influence exercised upon the imagination of the mother, by seeing a negro picture hanging near her bed. Heliodoro relates that, when a queen of Ethiopia gave birth to a white fœtus, this particular fact was explained by the impression made upon the labouring woman by the portrait of the beautiful Andromeda. According to Malebranche, a woman gave birth to a child with the arms and legs broken, in consequence of the mother having seen torn into pieces a criminal; and Damaseno relates, that he knew a girl that was born with the body covered with hairs, in consequence of her mother, having, during the pregnancy, fixed her attention upon a figure of Saint John dressed with a sheep skin. In spite of the prestige of antiquity, and of the vulgar acceptance of this doctrine, it is so unscientific, that it does not deserve the honour of a formal or serious refutation. All know to what extent we must believe (or how we may look), in regard to the influence exercised upon the fœtus by the imagination of the pregnant woman, and in the representation of the desired object in the *nævus materna* or *ephelides* in the children. Experience contradicts in the most determinate way, the pre-occupations that are only professed in these days by persons that like to live in ignorance. The imagination of the mother cannot have any transcendental influences upon the organism of the fetus, inasmuch, as the blood of the first does not pass substantially into the veins of the second. The product of the conception has an independent life, and during the embryonic state, it has not any connection with the uterus.

Another theory much more satisfactory and more in harmony with physiology is that which attributed the monstrosity to alterations accidentally produced in the product of the conception during the different periods of the intra-uterine life. If in the embryonic, as well as in the foetal state, the new being enjoys an independent life, how can we deny that this organism, like the others, might be the seat of certain morbid changes affecting its development, under the influence of conditions analogous to those which after birth give rise to pathological states. For the same reason that it is a living being, it may get sick, and its functions being reduced exclusively to those of formation and development, those most necessary are to be affected in any perturbation occurring in the intra-uterine life. The causes giving rise to these changes might be materially inorganic, but are inherent to the body of the fœtus, or also depending on alterations taking place in the vital medium in which it resides. Only in this last way and remotely can the moral emotions of the mother take part in the monstrosities of the fœtus.

The doctrine of those that admit that the monstrosities resultant from the exaggeration of certain anomalies pre-existent in the germs, although not unscientific it is hypothetical. In order that such an assertion might be received, it would be necessary to demonstrate the existence of aberration in the germs before receiving

the prolific impulse. This is the reason why such explanation is only accepted when the precedent theories cannot be applied. In fact, it is not shocking to admit it, after conception, the germ can suffer alteration in its development; the same perturbations can occur before fecundation, because, although considering the germ as a mere product of secretion, we find that, as the humours secreted by the glandular structures suffer modification, so it may be the seat of analogous alterations of the product elaborated by the ovaries or by the testicles. Could not that explain the hereditary transmission of certain congenital deformities?

Making application of these theories to the case in question, we find that this, as well as those produced by excess, adherence, or fusion, may be explained much better by the accidental alterations, than by the aberrations of the pre-existent germs. We have, in fact, anatomical proofs of the duplicity of the germs; it is only necessary to look to the drawing to see this evidently in the seat of adhesion. It is a case of double conception in which the ovum, after being fecundated, adhered reciprocally. But when and where did the fusion take place? Probably in the Fallopian tubes in the descent of the ova through this passage during the glairous state of the embryonic period. The adhesion, in fact, does not take place by the integuments, but by the osseous system, which proves that the germs ought to be in contact in one period in which the parts were so soft and diffuent, that they allow its reciprocal penetration; had the fusion been later, or in a more advanced period of development, it should have been limited to the skin. The fissure that indicates the separation of the two organisms was persistent. There was not, therefore, any fecundation of a double germ, but two germs fecundated at the same time, and afterwards fused in a point where they were put in contact. It happens, as in a hybrid in which two distinct plants remain fused in a single one, giving each the proper fruits of its species, although partaking both of the same.

If the extra-uterine life of this monstrosity had been possible, each individual would exercise separately its functions; then it would have been curious to observe whether the functions of the brains were individually or simultaneously accomplished. Certainly, the life of these two beings would have been very important to illustrate many problems of transcendental physiology.

Literature.

SICK CHILDREN (a).

If we mistake not, Dr. Hogg is the writer of those clever and amusing, although somewhat disjointed, letters in a weekly Medical contemporary, which treat "*de omnibus rebus et quibusdam aliis*," which everybody reads and everybody likes. The lecture before us displays all the best, and some of the worst, qualities of the author's style. Full of humour, abounding in anecdote and illustration, yet suggesting and enforcing graver thoughts, and always leading his hearers' and readers' sympathies in the right direction—there is yet an abruptness of style, a rapid and sometimes jerking transition from one train of thought to another, which somewhat jars upon the critical ear, although it was, doubtless, far less perceptible in the spoken lecture than in the printed page. Dr. Hogg appears to have had two special objects in the lecture—one to call the attention of parents to the essentials of health, the other to awaken and sustain a wider and deeper interest in the children of soldiers. We need not say that he lends to both no small amount of eloquence.

(a) "Sick Children." A lecture delivered at the Royal Artillery Institution, Woolwich, April 22nd, 1872. By Francis R. Hogg, M.D. R.H.A., &c., &c. London: J. and A. Churchill. 1872. Pp. 32.

and erudition, which, we doubt not, will fully achieve its objects. One of the facts he mentions is so curious as to deserve quotation :—

“During the space of ten years, scarlet fever has but once appeared in the female hospital (and that a mild, isolated instance), although during that time Woolwich was never free from visitation, and no particular precautions could be adopted. The explanation seems to depend on the fact of the wards being very cold; and cold, like light, is opposed to pestilence.”

How far the explanation tallies with the marked prevalence of scarlet fever in the winter months we will not stay to enquire, but conclude by most cordially recommending Dr. Hogg's lecture to the perusal of our readers, and expressing our sincere wish for further contributions from his facile pen.

ON CLINICAL EDUCATION (a).

THERE are many still living who can remember the days when it was thought neither impious nor impolitic for a great surgeon to publicly thank God for his ignorance of both physic and physiology. Nor was the physician of the period less illiberal in his notions of the dignity of the Profession, for he denounced the use of the test-tube in uroscopy as “unfit for a gentleman.”

Mr. Furneaux Jordan is well-known as a leader of that advanced School of Surgeons who are bidding fair to accomplish the unity of the Profession in spite of Acts of Parliament, Charters, and of all vested interests and prejudices. On the Continent Billroth is the best representative of this School. In our own country we have, happily, many more like him, and to increase their number is the worthy object Mr. Jordan has set before him. A couple of extracts will best show the thoroughness and catholicity of the author's views. First, from page 9 :—

“One great art in clinically teaching the rules or facts of disease is to classify them according to their importance. To interest and impress the student it is necessary to group clinical truths very much as an artist groups objects in a picture. The large objects must be in the foreground, they must be well-defined and stand in a good light; next to these are objects a little less noteworthy, and still further in the shade—are smaller, but still visible objects. So, in disease, there are the large truths, the truths only a little less in size, and the crowd of smaller truths. To put these clearly in their proper place is a laborious, but a much more effective educational means than to relate a dull chronicle of facts. There is as much difference between the two methods as there is between Carlyle's ‘History of the French Revolution’ and the driest chronicle ever written.”

Again, at page 11 :—

“Acuteness of touch, of the muscular sense, of sight and hearing, quick action, endurance, courage, are all necessary to give ideas their fullest value. Trained sight for the use of the microscope, ophthalmoscope, and laryngoscope; trained hearing for the stethoscope; trained touch for the detection of fluctuation, elasticity, doughiness, crepitation, and crepitus, are necessary adjuncts to trained observation and trained reasoning power. I have a strong impression that high nerve functions run together. Oftenest in the same man are combined the most delicate touch, the truest eye-sight, the keenest emotions, the clearest ideas, the strongest will, the promptest action.”

The whole lecture should be read by every clinical teacher, and by every Medical student in the three kingdoms.

(a) “On Clinical Education.” The Introductory Address to the Clinical Session, 1871-2, at the Queen's Hospital, Birmingham. By Furneaux Jordan, F.R.C.S., Surgeon to the Queen's Hospital, Professor of Surgery at the Queen's College, &c., &c. London: J. and A. Churchill. Pp. 13.

Medical News.

New York Academy of Medicine.—Dr. Tilt, of London, has been unanimously elected a corresponding Fellow of this Society.

Sewage in Towns.—On Wednesday last, a meeting of municipal authorities and others, interested in remedying the nuisance of sewage in towns, was held in Stafford House, by the kind permission of the owner, the Duke of Sutherland. The meeting was very well attended, and the chair was occupied by his Grace. The immediate purpose for which the meeting was called was, to discuss the plan of Major-General H. Y. D. Scott, for getting rid of such nuisances by fire; and to devise measures for applying the principle to the removal of the present difficulties. It might be as well to mention that Gen. Scott's process is in actual operation at Ealing, and that the subject has been discussed by the Society of Arts and the Architectural Association, Conduit Street. The Chairman introduced the subject by expressing the pleasure with which he saw so large and intelligent a meeting assembled, and called on General Scott to explain his method of dealing with the question of sewage. General Scott then proceeded to give a sketch of his plan, and the method adopted by him, which he thus summarised :—The sludge must be taken out of sewage water before employing it for irrigation. If the sludge be allowed to deposit on the land, it choked the pores of the soil and created an intolerable nuisance. Subsidence and straining without proper chemical precipitation did not efficiently clarify sewage water. When filtration was necessary for the complete purification of sewage, the better clarified the sewage water the less was the area of ground necessary for the filtering bed. The best clarified sewage was also the best for irrigation. Sludge deposits, whether dried or not, had little or no value as manure. The chief manurial value of sewage passed off with the liquid. A great variety of remarks and questions on these several points, proceeding from Mr. Morgan (Barking), Mr. Hawkealey, C.E., Mr. Rawlinson, C.E., Mr. Webster, Colonel Hogg, M.P., Mr. Bennett, Mr. W. Hope, Mr. Jones (Ealing), Mr. Bramwell, C.E., and others followed, which were answered by General Scott.

Apothecaries' Hall of England.—At a Court of Examiners held on the 18th instant., the following gentlemen, having passed the necessary examinations, received the L.S.A., Diploma, viz. :—Messrs. William Edward Balkwill, of Kingsbridge, Devon; William Allison Dunn, of Louth; N. A. R. Harrison, of Lambeth; Arthur Graham, of Castle Street, London; Herbert Alfred Lawton, of York Street, Borough; Herbert Price Taylor, of New Cross; and Mr. George Williams Parker, of St. Thomas's Hospital, passed the primary professional examination.

Hampstead Hospital.—The managers of the Metropolitan Asylums Board have resolved that no more cases shall be admitted to the Hampstead hospital, and that when the beds at present filled are empty the place shall be disinfected and prepared for imbeciles now in the London workhouses. All the small-pox cases arising in the districts hitherto covered by the Hampstead Hospital, will be sent to the Homerton or Stockwell Asylum. This course has been adopted owing to the great decrease of the disease all over London.

College of Physicians, Ireland.—At examinations held on the 8th, 9th, 10th, and 11th of July, the following gentlemen obtained the licence in Medicine and Midwifery : *Medicine.*—Samuel Brereton, Walter Charles Skardon Burney, Robert Fair Frazer, John Armstrong Irvine, Ayres Moore, Joseph John Nolan, Terence O'Brien, John Baker Reid, Richard Edm. Ross, Henry Plunkett Esmonde-White. *Midwifery.*—Samuel Brereton, Hugh Doherty, John Armstrong Irvine, Elias William Kerr, Ayres Moore, John Baker Reid, Henry Plunkett Esmonde-White.

The Horton Infirmary, Banbury.—The commodious and costly infirmary, presented to the inhabitants of Banbury by Mr. John Henry Horton, was formally opened on Wednesday last by the Bishop of Oxford. The infirmary, which has been named after the founder, as a token of gratitude on the part of the town, stands in thirteen acres of land, about a mile out of Banbury, and commands some charming views across a piece of country beautifully undulated and wooded. In addition to this, the situation is a remarkably healthy one, and in every way adapted to the purposes to which it has been applied. The total cost of the ground and building—both given by Mr. Horton—is £10,000.

The Cholera in Russia.—The cholera, says the *Eastern Budget*, has now made its appearance in various parts of Russia. At Moscow official bulletins showing the progress of the malady are being published daily. There were 78 cases between the 1st and 16th of June, and on the 17th there were 20 more. The number of deaths is on the average eight times as great as that of cures. At St. Petersburg two persons have died of cholera, and the papers urge the inhabitants at once to take sanitary measures with a view to preventing the spread of the disease. The great number of cholera patients at Kieff is attributed to the crowd of pilgrims who have recently visited the convent of Kiero-Petchersky, where the accommodation is quite insufficient for sanitary purposes, and it is proposed, in order to prevent the influx of any more pilgrims, to post placards at the principal stations on the railway, warning travellers of the risk of visiting Kieff at this season.

NOTICES TO CORRESPONDENTS.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this request.

All communications intended for insertion, must bear the name and address of the writer; not necessarily for publication, but as a voucher of good faith.

Rejected MS. will always be returned, if a request be received from the author, within one week after the article or letter has been declined.

SUBSCRIPTIONS IN THE UNITED STATES.—A Correspondent has drawn our attention to the fact, that some of the houses in the United States are charging the enormous figure of 15 dollars per annum (more than £3) for supplying this Journal to different parts of the States. We beg, therefore, to state that we shall be happy to supply the same regularly post free per annum, if paid in advance, for considerably less than half this amount, viz. six and a-half dollars (about £1 6s. 6d.), either direct from our offices in this country, or through our recognised agents in the United States.

TO OUR SUBSCRIBERS.—It having been suggested to us that it would be a matter of great convenience to Subscribers visiting the metropolis to know where they can give instructions for their letters to be addressed previous to leaving home, we have pleasure in informing them that the Publisher has consented to take charge of letters addressed to

his care, and that he will place a desk at the disposal of Subscribers whose names are upon our lists, for short correspondence, where such accommodation is desired.

W. B.—A Licentiate of a College of Physicians is frequently called "Dr." by courtesy. Obviously he is not "legally" entitled to the appellation which implies the Doctorate in some University.

INTERNATIONAL SYSTEM OF WEIGHTS AND MEASURES.—In the House of Commons on Friday last, Mr. J. B. Smith asked the Under Secretary of State for Foreign Affairs whether any communication had been received from the French government inviting Great Britain to a congress of nations on the subject of an international system of weights and measures: and, if so, whether the government proposed to send a representative to the congress. Lord Enfield said that the French government had notified that the international commission which was suspended in 1870 would resume its labours on the 24th of September next, and it was intended by the Board of Trade to send out Professor Miller and another gentleman to attend on the part of this country.

WANTED, A DEAF DOCTOR.—Upon the hoardings in the streets of London may be seen a placard as follows:—"Wanted, another Deaf Doctor for the City Police Hospital. Apply, &c." We confess to a happy ignorance of the meaning of this strange advertisement, and fall back for information upon those of our readers who are good at enigmas. We throw out this suggestion; is it a printer's error, and the authorities are in want of a *deft*, or perhaps a *daft* Doctor? The latter, probably as an excuse for some of the idiotic measures set on foot by them. Police, you are wanted!

THE FOOD REPORTS.—We are favoured by "Erva Lens" with another letter relative to the above question, in which he repeats, although in somewhat more polite language, the statements in his last, which appeared in our issue of the 17th inst. We inserted that letter—notwithstanding the forcible language used—in accordance with our accustomed practice of giving space to both sides of a question. As "Erva Lens" adduces nothing new in his second communication, we are unable to find room for it; his first, with our reply appended, must therefore stand on its merits, and so far as we are concerned, close the controversy.—[Ed. Food Reports.]

DR. BURGESS.—We forwarded your letter with addressed envelope to the Secretary of the Hospital, requesting him to send you a reply direct.

MR. C. R. C. T.—The price was corrected in proof, and inserted in proper form.

COMMUNICATIONS, Enclosures, &c., have been received from:—Dr. Hy. Bennett, London. Dr. Handzel Griffiths, Dublin. Dr. J. Eames Brown, Morland. Dr. Waring Curran, Mansfield. Dr. Harding, Sutton-in-Ashfield. Dr. Chapman, London. Dr. Lane, Ludlow. Dr. Piersol, Scarborough. Dr. Wilmot. Dr. Davidson, Chester. Mr. Stevens, Mr. Frank Buckland. Mr. Kemp. Dr. Harris, Redruth. Mr. Blacker, Midsomer. Mr. Hy. Murray, Portsalon. Dr. Mitchell. Dr. Macnamara, Torquay. Mr. Fox, Manchester. Mr. Hammond. Mr. Lang, Glasgow. Anthropos. Mr. Hyslop, Church Stretton. Dr. Fowler, Winkfield. Mr. Gorham, Tunbridge. Mr. Black, Edinburgh. Mr. Tichborne, Dublin. Mr. Golding. Mr. J. T. Jones, Weedon. A. S. Cowes. Dr. Dwyer, Tuscum. Dr. Dudley, Kenneley. Dr. Preston, Kilkel. Dr. Wharton, Dublin. Dr. Crowley, Kinsale. Dr. Underwood, Loughrea. Dr. Fallon, Athlone. Mr. Morris, Callan. Dr. Callan, Dundalk. Dr. Madigan, Drumclogher. Dr. McKear, Coleraine. Dr. Stoker, Dublin. Dr. Haughton, Dublin. Dr. O'Connell, Kilmacthomas. Dr. O'Hanlon, Rathkeale. Messrs. Savory and Moore. Dr. Gordon. Mr. Claron, Melbourne. Dr. Lynn, Sligo. Dr. Francis Hogg, Woolwich. Dr. O'Reilly, Trinn. Dr. Bennett, Ludlow. Mr. Thacker, Dublin. Mr. W. H. Hatfield, Dewsbury. Dr. Stanton, Galway. Mr. Gangee. Dr. Parker, Killarney. Dr. Shackleton, Husband's Bosworth. Dr. Dennehy, Clonmel. Dr. Brown, Esketh. Dr. Andrews, Chapelizod. Dr. Fitzerald, India. Dr. Thomson, Billboro'. Dr. McDonnell, Dunmore. Mr. Morris, Kilmogaony. Dr. Hayden, Dublin. Mr. Ponsouby, Dublin. Dr. Mitchell, London. Dr. Burgess, &c.

ERRATUM.—In our list of Medical Appointments published in the MEDICAL PRESS AND CIRCULAR of July 10, the name of Dr. Frank Thorpe Porter is inadvertently printed as one of the Medical Officers of the Dublin Eye and Ear Infirmary, in lieu of that of Mr. G. H. Porter, Surgeon to the Queen in Ireland, and Surgeon to the Meath Hospital, who is Consulting Surgeon to the Infirmary.

VACANCIES.

West London Hospital, Hammersmith. Surgeon. Honorary. (See advt.)

Board of Police, Glasgow. Sanitary Medical Officer, at a salary of £6 0 per annum. (See advt.)

Royal Hospital for Diseases of the Chest, London. Physician. Honorary. (See advt.)

Manchester Royal Infirmary. Physician's Assistant. Salary £54, with board.

Dorset County Hospital. Honorary Physician.

Warneford Lunatic Asylum. Medical Superintendent. Salary £260, with board and residence.

Hertford County Lunatic Asylum. Assistant Medical Officer. Salary £100 per annum.

Stourbridge Dispensary. House-Surgeon. Salary £120 per annum.

Devonshire Hospital, Buxton. House-Surgeon. Salary £100, with board.

Township of Manchester. Junior Assistant Medical Officer. Salary £120 per annum, with residence.

East London Hospital for Children. Medical Officer. Salary £80 per annum, with board and residence.

ETHER versus CHLOROFORM.

ON THE USE OF ETHER AS AN ANÆSTHETIC IN SURGICAL OPERATIONS; AS A SAFER AND MORE EFFECTIVE AGENT THAN CHLOROFORM IN PRODUCING THE AVOIDANCE OF PAIN.

With a Description of an Inhaler, and the Mode of Administration.

By J. MORGAN, M.D., F.R.C.S.,

Professor of Surgical and Descriptive Anatomy Royal College of Surgeons, Dublin, Surgeon to Mercer's Hospital, &c.

SINCE the all-important era of the introduction of anæsthetics into surgical practice, and the invaluable boon of the avoidance of pain, whether in small or large operations; claims have at times been set forth in favour of various means of attaining this desirable end—chloroform, ether, a mixture of both, nitrous oxide gas, &c., have had their advocates; and the great object of producing a temporary state of insensibility has been achieved by any one of these agents. Chloroform, undoubtedly, in these countries, has as yet carried the palm, and has had the most ample use: its successes can be counted by hundreds of thousands. No one who has either witnessed or experienced its value in the extinction of pain, can possibly doubt its efficacy, or can question the honours and laudations which have been so bestowed upon the late Sir J. Simpson as the introducer of this agent into practice; but in order to attain the state of "suspended sensation," even in small operations, and, in addition, to retain this condition for a length

of time, as is necessary in some of the larger and more tedious proceedings of surgery, the gauntlet of certain dangers, unfortunately, has to be run, which every practical surgeon will candidly admit, cause him much anxiety, and, I think I may add, in many instances impress him with responsibility far more than the operation in which he is about to engage.

The very appointment of special and skilled "chloroformists" to large institutions, and the anxiety felt that a Medical examination should be carefully made as to the condition of the heart and other organs of a patient about being operated on, lest any accident from chloroform should arise, proves the "arrière pensée" which admittedly exists in the minds of surgeons as to its dangers. How few would undertake the performance of even a simple operation, which involved the use of chloroform, without guarding against its risks, or without having by him the recognised means of restoring animation, and being prepared to apply them according to the emergency of the case; from the use of stimulants even to the last and critical resource of keeping up artificial respiration, as in ordinary instances of suffocation. Indeed, it must be admitted that in proceeding to operate, the surgeon should be accompanied not only by his assistants, but by a chloroformist, and the latter again should be furnished with the necessary means of combatting, not the results of the operation, but of the agent he is intrusted to administer, necessitating as it does an admission of responsibility, and of an inseparable amount of hazard, as proved by the arrangement of stimulants—ammonia, the galvanic battery, &c., so as to be at hand.

The danger of chloroform is an admitted one by the Profession, and is anxiously questioned by the Public. The chapters devoted to its consideration, and to the discussion of the use of "Anæsthesia in Surgery," by writers prove that, while chloroform stands as yet foremost in use in these countries, it has its inseparable difficulties, its dangers, and its anxieties.

The column "Death by Chloroform" is not unfilled, and the reports of coroners' inquests, where death has

been attributed to such cause, do not fail to produce so painful an impression of distrust on the public mind that a patient who has undergone its influence will, at times, recall his sensations in Endymion's words.

"Long in misery
I wasted, ere in one extremest fit
I plunged for life or death."

When to the deaths by chloroform we add those not unfrequent chloroform accidents, where artificial respiration alone restored the patient, where life was hovering on extinction, and where the faintest attempt at respiration was so anxiously watched for, and heard with such intense relief, though such cases do not come under immediate publicity, it must indeed be admitted they would tend very much to intensify the distrust which is more or less acknowledged, and is the real impediment of this "pain destroyer," when we are about, by its means, to use the words of a modern surgical writer (a), reducing the patient to a condition in "which, to the uninitiated, he appears in *articulo mortis*," and in "which very little more would place the circumstances in a most critical relation."

So important had the question of death by chloroform finally become, even in 1864, that a Committee was appointed by the Royal Medical and Chirurgical Society of London to inquire into the uses and the Physiological, Therapeutical, and Toxical effects of Chloroform. This Committee, composed of most eminent and painstaking observers, while investigating the subject of chloroform, indirectly considered the use of ether, which had been the first anæsthetic largely employed, and which is still employed in its birthplace, America, more largely, and far more successfully, than chloroform.

The accompanying tabular comparison gives a summary of the general conclusions arrived at by this chloroform Committee, with regard to the comparative dangers of chloroform and ether on the two chief functions of life—the circulation and respiration. It is interesting, as showing the more immediate interference of chloroform with them, and how easily, under any accident, a fatal issue might arise. We find as follows:—

**EFFECT OF CHLOROFORM
INHALATION.**

The Heart

Is first stimulated, and its contraction force augmented; but, after this, its action is depressed and, although the respirations go on properly, its action, as shown by the mercury of the hæmodynamometer when connected with the circulation of the animal, fails; and the mercury falls.

The Respiration.

With strong inhalation there is a temporary arrest of respiration dependent on spasm. This arrest, after a few seconds, ceases, and inhalation can again take place; with smaller quantities, the inspirations become gradually shallower, and for a time retain their natural order, but become less frequent; and after perfect insensibility

EFFECT OF ETHER INHALATION.

The Heart.

The muscular movement is but little influenced. The first or stimulating effect is less sudden, and more sustained. Even after insensibility is procured, its action is more vigorous. Ether may be considered as a stimulant in a certain degree to the heart's action. The mercury of the hæmodynamometer at first is absolutely raised—never falling till the respirations cease.

The Respiration.

With strong inhalation there is a temporary arrest of respiration, but it is less marked than with chloroform. With small quantities there is no arrest of the breathing, although the number and depth of the respiratory efforts are diminished; after a short time the respirations become slow and full, and next, while their frequency

produced, the amount of air entering the chest is extremely small.

How it Arrested Life.

Strong inhalation caused the pulse and respiration to cease nearly simultaneously. In the majority of cases the pulse stopped before the respiration, and the heart's action could be distinguished for some time after the pulse had ceased.

rises, the range of their movements is reduced.

How it Arrested Life.

The effects produced in a strong quantity, equalled those of chloroform in a small, but with an important contrast—that it exerted but a very slight depressing influence on the heart. Death occurred by the failure of the respiratory movements—the heart's pulsations continuing generally for sometime after the respiration has ceased.

The conclusion formed by the Committee was, that it is desirable to obtain an agent which shall produce the required insensibility, and yet is not so dangerous in its operation as Chloroform. Ether, to a certain extent, fulfils these conditions: it is less dangerous than chloroform; but its odor is disagreeable: it is slow in operation, and it gives rise to greater excitement than chloroform. The Committee, therefore, admit the comparatively greater danger of chloroform, while ether is objected to but for the three inconveniences mentioned.

The Committee states that "the only apparatus known for chloroform administration, which fulfils the necessary conditions, is that contrived by Mr. Clover; but at the same time it is open to objections," which can be easily understood, of non-portability, &c. Although the admixture of air is obtained by its means, yet even then the members admit that, "with every care, and with the most exact dilution of the chloroform vapour, the state of insensibility may pass in a few moments into one of imminent death!"

Dr. Ellis, in his treatise, 1866, since published, throws considerable doubt on the possibility of an even admixture of air and chloroform being attained by the instruments in use at the time of the Report of the Commission.

On examining the Report of the Commission at that date, June, 1864, a table of 123 deaths occurring "during, or immediately after, the administration of chloroform," is recorded—109 deaths being thus given:—

Under 5 years	-	-	0
From 5 to 15 years	-	-	9
From 15 to 30 "	-	-	30
From 30 to 45 "	-	-	32
From 45 to 60 "	-	-	12
Over 60 years	-	-	2

72 cases were in males, and 32 in females.

Many other dubious cases, no doubt, might be enrolled in this category; but for obvious reasons, deaths from chloroform may be pardonably, perhaps, excused recording. But when at that date so many were admittedly due to its influence.

How many more, it may be fairly asked, have occurred since?

On the other hand, Ether admittedly is comparatively free from this very unpleasant accident. I am assured by Dr. Godon, late Resident Surgeon at Charity and Bellevue Hospitals, New York, that he has, during the last four years, seen and assisted at thousands of cases of Etherisation where, while the most satisfactory results, were obtained, not the slightest accident occurred, nor was in any way anticipated. The usual "armamenta" accompanying the chloroformist, of stimulants, galvanic apparatus, &c., being absolutely unheard of. I have myself Etherised and operated on thirty patients during the last ten days with the most satisfactory results, and the most comfortable sense of security, as compared with chloroform, justifying almost the observation of M. Diday in the recent discussion on another death by chloroform at the Société de Médecine, Lyons, which puts the matter in so

(a) Miller's "Surgery," p. 682.

strong a light, that the advantage of Ether as "less dangerous than chloroform" must command attention.

The *Gazette Médicale de Paris*, July 13, states:—"A case of death from chloroform has just been reported, which occurred May 27th. Professor Billroth was proceeding to amputate at the hip-joint—the femoral artery had been tied—and he was about to divide the soft parts with the galvano-cautery, when the breathing became stertorous. Tracheotomy was performed, the windpipe opened without delay, and the other means used for re-animation, but all was useless—the patient was dead." Another case of death by chloroform, during an amputation of the thigh, was given by M. Cabasse to the Société de Médecine at Lyons.

The Society then entered into the discussion of the comparative merits of ether and chloroform as anæsthetic agents; when, for the third time, the Society pronounced in favour of *Etherisation*.

In Lyons the generality of surgeons employed ether to the exclusion of chloroform. Some surgeons there, however, still were in favour of chloroform. M. Diday indeed proposed the adoption of conclusions by the Society so strong as that "chloroform is dangerous, and that the surgeons who use it are culpable," which, in fact, would be a foregone condemnation of any surgeon who used it, should a death occur while under its influence. A Commission of Enquiry was formed by the Medical Society, and a report by Mr. Valette of the conclusions arrived at was read. Subsequently, the Society hesitated to take upon itself the responsibility of adopting the sweeping proposal of M. Diday, and limited itself to pronouncing in favour of *Etherisation*, and admitting that the comparative study of the two anæsthetics was far from being complete.

The Society voted the permanent sitting of the commission on the subject for further investigations.

The report of the London Commission of 1864 states "That the sequence of the phenomena during the experiments on animals is similar to that observed in man, and if the same percentage of the agent be administered, the results produced are nearly uniform." Much valuable information may, therefore, be obtained by comparative testings on animals, they are of so simple and reassuring a nature that a performance of them will go far to show the superiority of ether as an anæsthetic agent, leaving the triple argument of "disagreeable odour" (a), "greater liability to cause excitement," and "its greater tediousness," to be further discussed and observed upon; objections, which seem to me so insignificant, even if we admit them (which I do not) as compared with *danger to life*, that I cannot believe they could for a moment be of weight. I have made some careful enquiries on the subject, and I made, amongst others, the following very interesting observations:—

Four healthy rabbits of the same clutch were selected.

OBSERVATION No. I.

Nos. 1 and 2 were comparatively tested as follows:—

No. 1 was enclosed in a 10-inch glass bell, with two drachms of chloroform on cotton.

No. 2 was similarly enclosed, with four drachms of methylated sulphuric ether.

Result.—No. 1 became influenced in two minutes, slightly convulsed, lay over on its side in one minute more, the bell was then raised, and the rabbit found in a state of anæsthesia, in which it remained for five minutes, and then gradually recovered.

No. 2 became evidently influenced in four minutes, and in five minutes more the bell was raised; was in a state of anæsthesia, in which it remained for seven minutes longer, and then gradually recovered.

The rabbit treated by ether had no convulsive stage whatever, but gradually sank as it were into a deep sleep, lying out flat and not on its side; the respirations were

hastened, and not interfered with as to regularity; but they were rendered very irregular in the one treated by chloroform.

OBSERVATION No. II.

Rabbit No. 3 was enclosed under a glass with 1 oz. (by measure) of methylated sulphuric ether. In two minutes it became influenced, and went quietly asleep; breathing quicker, 128 per minute.

Rabbit No. 4, tested with four drachms of chloroform, in two minutes it became influenced, was convulsed slightly, and uttered piercing cries; breathing became slower, 44 per minute.

Both recovered gradually (within eight minutes), the etherised one more gently and naturally.

OBSERVATION No. III.

After the lapse of half an hour, rabbit No. 1, which had been before chloroformed, was again enclosed in the glass cover, with eight drachms of chloroform sprinkled on wadding. In one and a-half minutes it became influenced and tolerably convulsed; the eyes were greatly suffused; it uttered cries in two minutes; total and profound anæsthesia ensued in four minutes; respirations, 80 per minute.

Rabbit No. 2, which had been before etherised, after the lapse of half an hour, was enclosed by the glass bell with twelve drachms of ether. In two minutes it became heavy and sleepy, and in five minutes was thoroughly insensible; it uttered no cry; the respirations were 112.

In this experiment the etherised rabbit became sensible after twenty minutes; it gradually recovered and crept about, scenting its companion which lay beside it, thoroughly insensible and congested, in ten minutes more the chloroformed rabbit became gradually restored, but remained unsteady and evidently "dazed" for some time longer.

OBSERVATION No. IV.

A small quantity of chloroform and ether respectively was now tried with the rabbits used in the second experiment, and after a lapse of twenty minutes full recovery.

Rabbit No. 3.—Two drachms of the same ether was tried in the same manner under the glass bell. In one minute, the animal became influenced and gradually became insensible within five minutes.

Rabbit No. 4, which had before been chloroformed, was tried in the same manner, with but two drachms of chloroform. In one and a-half minutes it became influenced, and within five minutes was insensible. Within fifteen minutes both gradually recovered, but the one etherised more rapidly and perfectly.

On analyzing these observations, the superiority of ether is evident as to its harmlessness. In Observation Nos. 2 and 3 it would seem that the animal suffered from the chloroform, as the piercing cry heard from a rabbit when in extreme terror, or pain, was uttered.

The convulsions in experiment No. 3 (where the larger quantity was used) were very marked, and persisted during half the period of recovery, and though so large a quantity of ether (one ounce and a-half by measure) was used in the same experiment, there was no spasmodic symptoms whatever. The sleep (if it may be so termed) was much more natural in the etherised rabbits; the respirations were somewhat increased.

The anæsthesia from one agent was apparently as profound as the other, while the ether acted more gently, more equably, and without the convulsive stage, which is so unpleasant to witness in patients, and sometimes so difficult to control. The etherisation tested both in large and small quantities gave parallel results, producing a more equable, gentle, and unalarming insensibility. From the mode in which these experiments were conducted under glass bells of equal dimensions laid on a table—of course, a certain amount of air was inhaled, and the agents were so diluted—I further tried the comparative results of inhalation, with undiluted ether and

(a) Dr. Godon, who has seen in America many etherisations, both on animals and human beings, kindly assisted me, and witnessed the results.

undiluted chloroform, on the rabbits which had already been tested. Accordingly, about one drachm of ether was dropped on a cloth, and the nose of No. 2 rabbit enveloped by it, so that nothing almost but the ether vapour was inhaled. In one minute the animal became influenced, and sank gently into insensibility, from which it recovered within five minutes, and seemed as well as ever.

No. 1 rabbit was exposed in like manner to the inhalation of about half a drachm of chloroform. The cloth was wrapped round the nose. In one and a-half minutes it sank into insensibility, uttered cries, and was slightly convulsed. The cloth was immediately removed, respirations ceased in four minutes, and the animal died just in the circumstances such accidents as "deaths from chloroform" have been reported. These comparative observations on animals which had been subjected to the same testings, and within the same time, tend to put the superiority of Etherisation strongly in contrast with that of Chloroformisation; the crucial test of the inhalation of undiluted ether *versus* chloroform, showing that insensibility could be produced for the third time, within one hour and a-half, with perfect success, and without any bad consequence; while a small quantity of undiluted chloroform produced death when similarly tested. These observations are of so simple a character that anyone can repeat them who may doubt the effect—of course, such reasonable precautions should be taken with both agents as would be applicable in the case of human beings.

(To be continued.)

Hospital Reports.

MEATH HOSPITAL, DUBLIN.

Cases under the care of Mr. L. H. ORMSBY, Surgeon to the Meath Hospital, and Demonstrator of Anatomy in the School of Surgery, Royal College of Surgeons in Ireland.

(Reported by Mr. P. TUTHILL.)

CASE I.—*Extensive Syphilitic Ulceration of Throat—Recovery.*

WILLIAM CORCORAN, *æt.* 26, a harness-maker by trade, was admitted into the Meath Hospital on the 10th of June, 1872, suffering from extensive ulceration of the throat.

History.—He states he had a chancre on the glans penis about a year ago, the chancre healed in a short time under treatment, his testicles were both very much enlarged at the time; four months afterwards, a rash came out on his back between his shoulders, and he had great pain in his back and loins. About a month ago his throat became very sore, and gave him great pain in swallowing, his voice became husky, and being very intemperate and greatly addicted to drink, his throat became greatly worse, so much so, that he could only swallow liquids, and those with great difficulty.

State on admission.—He was greatly emaciated and hardly able to walk; saliva running from his mouth in great quantities; he also had a husky racking cough, which kept him awake at night; on looking into his throat, the soft palate was found extensively engaged, the anterior half-arch of his palate, the uvula and an ulcer was seen on the posterior and upper part of the pharynx; there was no sore on the glans penis or prepuce, but both his testicles were very much enlarged, the right rather more than the other.

Treatment adopted.—He was ordered to lie in the recumbent position—a mixture containing

R Iodidi potassii, ℥j.;
Chlorate potassa, ℥j.;
Tinct. cinchona, ℥ij.;
Syrupi aurant, ℥v.;
Infusi cinchona, ad ℥vij.

Fiat mist. cujus sumat coch. duo ampla, *ter indie.*

A gargle containing eight ounces of the lotio. nigra was ordered to be used often in the day; the man was put on good generous diet, and four ounces of wine in the day.

11th of June.—The day after his admission he could hardly swallow even liquids, the slightest movement of the muscles of deglutition giving him pain; his throat was then swabbed out with a dossil of lint steeped in a solution of chloride of antimony. This gave him great pain and uneasiness, but the next day he seemed greatly relieved. He frequently gargled, with the black wash, and the ulcers very soon began to heal. He was allowed to get up on the 16th of June, and the iodide of potassium was increased from a drachm to a drachm and a-half to the eight ounces of infusion of bark. On the 26th of June, the ulcers had all healed, his uvula had not been destroyed, and his speech was perfect. He left the hospital on the 27th June, 1872, perfectly well, with the exception of a slight enlargement of the right testicle, the left being of the normal size.

Mr. Ormsby drew the attention of his class to this case, enumerating the many and varied situations and ways in which syphilis affects the system, and also the importance of a correct history of the receipt of a chancre—a bubo—rash—as all contributed to form a true diagnosis. He then spoke of the treatment, saying that the gargle he had ordered was rather uncommon, and perhaps unpleasant to the patient's taste, but it was most efficacious in healing up all kinds of syphilitic sores on mucous surfaces. He also said that iodide of potassium in all stages of syphilis was admissible, and in those cases where it was not, you might then use mercury. He also spoke of the great use of the application of lint steeped in buttyr of antimony, to the edges of the ulcer, having the advantages over the other liquid caustics by not spreading beyond the part touched, and the marked improvement which resulted from its application in this case.

CASE II.—*Extensive Scalp Wound—Recovery.*

James Dunne, admitted into the Meath Hospital on April the 22nd, 1872, suffering from a very extensive scalp wound, which he states he received by knocking his head accidentally against an arched iron gateway, as he was passing through. The wound extended from the frontal eminence, passing across the vertex of the skull to the occipital protuberance, laying bare the bone—the lips of the wound were wide apart and gaping.

Treatment adopted.—The hair was shaved along the edges of the wound for about two inches, and the edges of the wound were gently brought together with adhesive plaster and simple water dressing employed. The man was put to bed, and kept on low diet. In two days the wound began to suppurate, which rapidly extended beneath the scalp, and caused a great deal of pain to the patient. A linseed meal poultice was then applied, and the wound was sponged out twice a day, and afterwards syringed with Condy's fluid; all pus that had formed was passed out, and the greatest cleanliness observed, his bowels were kept gently open by the administration of mild aperients, and the following mixture ordered to procure sleep, as he complained very much for the want of his night's rest:—

R Hydr. chloral, gr. xv.;
Tinct. hyoscyami, ℥ss. = $\frac{1}{2}$;
Aqua camphora, ad ℥ij. m

To be taken every night.

May 10th.—Less suppuration, and the wound cleaner and studded with florid granulations; the linseed meal poultice discontinued, and a solution of chloride of lime ordered to be applied; he was then put on liberal diet,

with a pint of porter, and was discharged on May 24th, quite well.

Mr. Ormsby gave a short clinique on this case, and drew the attention of his class to the mode in which he brought the edges of the wound together, saying that it was not considered good practice to apply sutures of any kind in scalp wounds. The next point he mentioned was to cleanse perfectly the wound from clay, hair, and all foreign matter, so as to ensure healing by the first intention if possible, and also to bring the edges in perfect apposition. He also said that of all wounds, wounds of the scalp were most often followed by erysipelas, and that in this case, that was the danger he was most afraid of, but happily it did not occur, and that was the reason he kept him on low diet and his bowels freely moved, and that, when suppuration ceased and the danger more or less passed away, he then changed his treatment, and, lastly, he said that in these wounds sleeplessness was nearly always complained of, and he commended strongly for such a case the mixture ordered.

CASE III.—*Fracture of Humerus.—Recovery.*

Catherine St. Ledger, *æt.* 58; admitted into the Meath Hospital on the evening of the 19th of April, 1872; suffering from fracture of surgical neck of humerus. History states that she had fallen from a ladder about four feet in height while cleaning a window.

Treatment.—The limb was put up comfortably in two splints, one a short piece of scored splint-wood, reaching from the axilla to the elbow on the inner side of the arm; the other, a piece of gutta-percha moulded into the shape of the limb and extending from above the shoulder to the elbow on the other side, the hand, forearm, and arm evenly bandaged, and the arm confined to the side with the forearm flexed across the chest. The woman went on remarkably well till about four weeks after admission, when she caught cold and got an attack of acute bronchitis which very nearly carried her off. The usual medicines were ordered, but she became much worse—she was then ordered mustard poultices to her chest, and after turpentine stupes as she felt no relief from the mustard, and after that a large linseed meal poultice to be applied to the back of her chest, and twenty drops of spirits of turpentine to be taken in punch ordered. She soon rallied under this treatment, and left the hospital on May 30th.

Mr. Ormsby said a few words about this case. Mentioning the diagnosis of fracture in this situation, and enumerating the symptoms, namely, slightly shortening crepitus, the upper fragment drawn upwards and outwards and the lower drawn inwards, and a correct knowledge of the anatomy of the part would aid you greatly in a correct diagnosis. He also enumerated the successive stages that take place in the repair of a fractured bone, and that in about six weeks you might allow your patient to use the arm slightly but in a very cautious manner, and, of course, the older the patient the longer period you would expect for its repair.

CASE IV.—*Nasal Polypus.*

Rose Walsh, *æt.* 73, was admitted into the Meath Hospital on July 17th, 1872; suffering from a large polypus, blocking up the left nasal cavity. History states that about three months ago she caught a heavy cold, and ever since she felt a stiffening sensation in her nose, and always felt worse in damp and wet weather.

Treatment.—The polypus was removed by a polypus snare, which was introduced cautiously into the nostril and the woman desired to blow through the affected cavity, which at once became surrounded by the wire loop of the snare which was then tightened and the polypus removed without further difficulty.

Mr. Ormsby drew the attention of the class to this case:—1st. Enumerating the different kinds of polypi met with in this situation, and the different modes of treatment recommended by surgical writers. The treatment adopted in this case was, to his mind, simple, rapid, and efficacious.

Transactions of Societies.

MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS.

MR. CHARLES R. C. TICHBORNE, F.C.S., M.R.I.A., read a paper on

DISINFECTION IN CONNEXION WITH SMALL-POX.

It has been conclusively proved that all rooms are filled with a certain amount of dust moving about in variable quantities—at least, to all intents and purposes, it may be considered as never being absent. The greater proportion of this dust, as shown by Tyndall in the analysing tube, is organic, or, in other words, can be destroyed by heat. As regards experiments performed upon the development of bacteria, they would properly only bear upon epidemic diseases from this point of view; but I myself do not see that there is anything particularly to connect them with small-pox or such like contagious diseases. They are always the forerunners of putrefactive change where atmospheric air has been in contact, but this simply proves that the germs of bacteria are always present in ordinary atmospheric air. Here is a substance that was once a solution of milk sugar, now converted into solid lactate of lime by germs taken at as high an altitude as the top of Nelson's Pillar. But these results can be obtained equally well when there is no small-pox in the city.

There is, however, another view to take of the atmospheric propagation of disease, which, I think, has been too much lost sight of. This is the mechanical action of this dust, or the raft theory, as I will call it. I, however, lay no claim to the use of the word raft. It was used by Professor Tyndall in one of his lectures to explain how the particles of a *non-volatile* salt, chloride of sodium, were always found in the air. Now, as we know that the virus of small-pox may be dried without impairing its activity, we have all the requisites for dissemination by the atmospheric rafts. If we consider the immense amount of inoculable matter that is disseminated in a city like this, where 600 to 700 lie ill of the same contagious disease, we shall see no difficulty at arriving at this conclusion. I have no hesitation in saying that there is not a cubic inch of atmosphere in Dublin where the small-pox virus is not. But, like all poisons, there is, I suppose, a point of attenuation where it is inert, and to keep it below that point is the great use of volatile disinfectants. The dried virus floating upon those rafts cannot be affected by non-volatile disinfectants.

I am of opinion that it would be dangerous in the extreme to cast away these now old and well recognised friends. In fact, to me it seems to be only within the last few years that we have been beginning to understand the principles of disinfection. Does not the real difficulty of disinfection lie in our misapplication of each particular disinfectant which has its peculiar function, and our want of knowledge of its action on those germs at present unknown? If we use chlorinated lime to disinfect a room (chlorinated lime being simply an oxydiser), what do we do but facilitate the efforts of the atmospheric oxygen to purify by oxydation. We charge the air with nascent oxygen, or that element in its most active form. Thus this air that had been already artificially deprived of its activity outside by contact with contagious matter, is re-oxydised to its maximum capacity. Now, although this is quite consonant with our chemical knowledge, it might be said that, after all, it is but a theory; but let us see how it agrees with our experience.

On the first week in November, 1871, in an establishment the name of which, from obvious reasons, it is not desirable to mention, a case of small-pox occurred. As there were about 200 beds upon this establishment, it is almost needless to remark that considerable alarm was felt by those with whom rested the responsibility of management. A consultation was held, and a well-known and well-advertised disinfectant was used with every precaution as regards cleanliness. Imagine the consternation when case after case was sent out of the house, until the eleventh was taken to the hospital on the 6th January, who died on the 11th of the same month—a case every fifth day. A consultation was again held, and with advice the following plan was adopted. The disinfectant was changed, and the use of carbolic acid and chlorinated lime was agreed upon. The carbolic acid (pure) was chiefly used in

water-jugs, a few drops in each jug. A man was told off especially to disinfect the place, and to do nothing else. In the morning he made his solution of "chloride of lime," about $\frac{1}{4}$ lb. or 1 lb. to the gallon of water, in a large tub. It was allowed to subside, so that it was quite bright and clear when he wanted it for use. At three o'clock p.m. he went through all the rooms, sprinkling the solution over every floor, and the windows were left open, so that the rooms were dry by the time they were required for use, equal attention being paid to the mechanical cleaning of the walls. The change in the system of disinfection was made on the morning of the 11th of January, the day when the last case was buried, and from that day to the present there has not been a single case of small-pox in this seething mass of humanity (a). Permanganate of potash is invaluable for certain special applications. Here is a simple experiment, which, I think, conclusively proves the value of chloride of lime as an oxydiser. I blow through a series of wash bottles and tubes. In the first bottle the air traverses a fermenting mass containing a weak solution of a ferrous salt. If the air contained any readily available oxygen (it matters not whether we consider it ozone, or condensed oxygen, or nascent oxygen, if it does its work), it will be deprived of it. This fact is demonstrated by being passed over ozone test-paper contained in the next tube. There is no evidence of decomposition. It is then passed in the next bottle through water containing a few drops of chlorinated lime, and then through a wash bottle containing a solution of ammonio-chloride of silver to remove any trace of chlorine. It lastly passes through a tube containing the ozone paper, which is now seen to be rapidly acted upon by the air. It is completely changed in its character, and is now a powerful oxydiser; and it is immaterial to our purpose how this has been brought about. It is now replenished, ready to do its duty and fight the battle with the rafts of contagion, and if it only succeeds in further attenuating the effects of this poison by burning up a fraction, the "disinfectant" has done some good.

Xylol's action is said to be due to the fact that it becomes an antiseptic in the blood. Now it is probable that if it does act as such, it is due to some product of oxydation. That it is really rapidly oxydised there can be no doubt from the fact that a peculiar odour, distinct from xylol, can be perceived in the urine.

From the reports of the Medical men I should consider the efficacy of xylol as doubtful, but it is self-evident that it may not necessarily possess specific properties to be an active medicine. I would require a lengthened experience of its capabilities at the bed-side to determine its actual value in the human laboratory. Although its action may be generally prognosticated, it can never be proved in the test-tube.

I have tried experiments upon dilute solution of albumen and vibrios from which it would appear to me that the dilute solutions of carbolic acid destroy the activity of the vibrios before they coagulate the albumen. The more diluted the solution of carbolic acid the more marked is the phenomenon. The sulpho-carbolates being crystalloides are more suitable for diffusion than the carbolates, whilst the residual carbolic molecule acts as if uncombined. In addition to the sulpho-carbolates of iron and sodium, I should suggest the use of the potash salt, which, from its action upon the skin and kidneys, would probably be useful. It is readily prepared.

In seeking for a remedy for internal disinfectives of the blood, it is evident, from my point of view, that we should try to search into the substances which will produce in the blood the antiseptics slowly, but in a nascent condition.

As I have studied the subject of disinfection and atmospheric dust with some care for years, I thought that these observations might be of use from the very fact of being trammelled by the ideas of a chemist. Out of a great mixture often comes good compounds. I almost feel that we are in a degree neglecting our duty in not constructing committees of investigation upon such occasions as the present visitation.

DR. CAMERON said, as he had recently read a paper on this subject he wished to make a few observations, more especially as he apprehended that the views Mr. Tichborne had put forward might appear to clash with those which he had submitted to the Society. He (Dr. Cameron) did not at all doubt the efficacy of gaseous disinfection to a certain extent, but what he said was this—and he spoke from the results of his own experience—that gaseous disinfection, as ordinarily carried out,

was totally inefficacious as a means of wholly destroying germs in a room. He held that the recent experiments of Chauveau—who occupied the first position as an investigator in this department of Medical science—and more recently the experiments of Dr. Burdon-Sanderson, one of the Medical inspectors of the Privy Council and professor in the Brown Institution, rather indicated that as a rule the contagious matter of zymotic diseases was deposited on solid substances. The great use of the disinfection at present employed was that it obliged people to open the windows and let in the fresh air. They all knew how well the Germans did everything in scientific and Medical matters, and he would mention the results of their experience of disinfection during the visitation of cholera in Leipsic in 1866. The chemical Professor, Carus, was appointed head disinfecter of the town, which was divided into 100 districts, each of which had a separate inspector. Never was disinfection more thoroughly carried out. Every house in which cholera appeared was disinfected with chlorine gas. And what was the result? There had been thirteen outbreaks of cholera in Liepsic since the first appearance of the disease in Europe, and never was the attack so severe as in the year 1866, when disinfection was carried out in so careful a manner. It was the same in Stettin and Erfuth, where disinfection was carried out under the orders of the Government and by a staff such as we could not have in this country. His views had been adopted by the Public Health Committee of the Corporation. They had increased their staff, and now, instead of merely disinfecting a room with chlorine gas, they removed the paper, if there were any, from the walls; scraped off the old whitewash, and whitewashed the walls afresh. If the whitewash did not destroy the infectious matter, at all events it imprisoned it. By the use of common water and whitewashing more good would be effected than by the circulation of thousands of feet of chlorine gas.

DR. HAYDEN said he was particularly pleased at hearing Mr. Tichborne's paper read so soon after the paper of Dr. Cameron, which, with all respect to him, he thought missed the point. Dr. Cameron seemed to think the atmosphere could not be a medium for the conveyance of disease. That, however, he (Dr. Hayden) doubted. Dr. Cameron, that evening, said it would be sufficient to cleanse the walls, but if it be true that the air was impregnated with organic matters, every one of which might be the medium for conveying the *morbis materia* of disease, he could not see how that could be neutralised without acting on the whole body of air in the room. He was glad to hear this practical paper of Mr. Tichborne, because the opinions urged in it had fallen in with his own preconceived views.

MR. TICHBORNE, in reply, said that Dr. Cameron, who had not heard the whole of his paper, had mistaken the drift of it. His theory was that the contagious matter of small-pox was a substance which was carried on the atmospheric rafts, and deposited on the clothes. Before it could be deposited on the clothes it must have passed through the air; and he proposed to act upon it by gaseous disinfectants. Dr. Cameron believed in the germ theory of disease generally. There was evidently something in it; but if he believed in it, one thing was self-evident—namely, that non-volatile disinfectants could do no good, for they could not touch it; but volatile disinfectants would be found effectual; and this was wonderfully borne out by the case he had stated that evening, which was only one of several similar cases that had occurred under his own observation.

The meeting then adjourned.

Extract of Meat.

PROFESSOR ARTUS, of Jena (*Wim. Med. Zeit.*, No. 3, 1872), recommends a new method of making extract of meat, which possesses the advantage over that of Liebig in retaining the albumen, gelatine, and fat, which are all removed by Liebig's process, and which would seem, from recent experiments, to be the only really nutritious elements of the meat. For this purpose, by a very simple apparatus, an extract of the meat is made first with cold water; this dissolves out the soluble salts, the albumen, and part of the gelatine and creatine. The meat, after extraction in this way with cold water, is then boiled for an hour in a Papin's digester, and the liquid pressed out. The fat is skimmed off the surface, and this extract is mixed with the cold extract. The mixed extracts are then evaporated down to a proper consistence in a sand-bath, or better, in a vacuum-apparatus.

(a) On the 24th of June, when this paper was going through the press, this house was still free from any case of small-pox.

REPORT ON THE FARINACEOUS FOODS NOW BEING ADVERTISED AND LARGELY USED FOR DIETETIC PURPOSES.

(Continued.)

MELLIN'S EXTRACT FOR PREPARING LIEBIG'S FOOD FOR INFANTS.

Manufactured by J. Mellin, 16 Tichborne Street,
London, W.

SPEAKING of this Food, Mr. Mellin remarks:—"A satisfactory substitute for mother's milk has long been sought after by persons who have witnessed the evil effects produced by every kind of food which is ordinarily administered to the infant when, from any cause, the mother cannot sufficiently nourish it. It is proved beyond dispute that the amazing amount of mortality among infants arises chiefly from disorders of the stomach, caused by their being fed with food deficient in nutriment and difficult of digestion, and so producing convulsions, diarrhoea, and other ailments, of which death is but the unhappy climax. Baron Von Liebig, having for some time noticed these evils, at length set his wonderfully acute and inventive intellect to solve the problem how infant life could best be preserved, and, after much study, succeeded in producing an artificial food which is as easy of digestion and as nutritious as mother's milk itself. Experience has, in fact, shown it to be so admirably adapted for the purpose he had in view, that it scarcely needed the recommendation of the chief men of the Medical Profession, many of whom (including all the great hospital physicians of London) have pronounced it to be invaluable, and prescribe it regularly for infants and invalids insufficiently nourished. By evaporation, the nutritious parts of the food are reduced into a powdered extract, suitable for transportation by sea or land into any climate, without in the least injuring the composition or altering its properties. By means of this extract the genuine Liebig's food can be prepared by mothers or nurses for their infants more easily and speedily than common milk pap. Liebig's invention is thus brought within reach of everyone, both at home and abroad, in the most compact and portable form. The extract has been obtained by most faithfully adhering to the original formula, by means of which the flour is so thoroughly transformed into dextrine and grape sugar by the malt, that the digestive organs of the weakest infant or invalid can assimilate the food without difficulty."

"Dr. F. Versmann's Report on Analysis of Mellin's Extract for preparing Liebig's Food for Infants.

"150 Fenchurch Street, E.C.,
"April 20th, 1871.

"Sir,—I have analyzed a sample of your Extract, and I find it to contain the following constituents, viz.:-

Grape Sugar	27.07 per cent.
Dextrine	9.59 "
Bicarbonate of Potash	1.82 "
Soluble Phosphoric Acid, 0.41 per cent., equal to Soluble Phosphate of Lime	0.79 "
Nitrogen	2.56 "
Insoluble fixed residue	0.32 "

"It does not contain any starch, showing that the decomposition of the flour into soluble grape sugar and dextrine has been completely effected. It is also free from caramel—a proof the care and attention you pay to the evaporation of the Extract.

"I am, Sir, your obedient,

"FRED. VERSMANN, Ph.Dr."

Mellin's extract is sold in bottles containing 8 ozs. at 1s. 6d.

It is in granules having a sweetish taste of malt, and is nearly soluble in water. It contained:—

Moisture	5.6 per cent.
Grape-Sugar and Dextrine	44.5 "
Ash, rich in the Phosphate of Potassium	2.3 "
Nitrogen	2.0 "

This preparation is, in fact, an excellent attempt to give the extractive and soluble portion of Liebig's food without the cellular and indigestible part of the meal. In the other preparations of this class this was partially avoided, but not wholly so by straining. It is not, however quite so palatable, in our opinion as that made directly from the meal. There is no evidence of starch remaining in this preparation (it having been all converted into grape-sugar dextrine), and there is no reason to believe that it is prepared from anything but malt and wheat. As a food for delicate infants there can be no question as to its great value.

EVANS'S EXTRACT OF MALT

Prepared by J. Evans, M.D., Dublin and London.

Testimonials and analyses from Professors Apjohn, Tichborne, and Galloway, are given. The following is printed on the label of the bottles:—

"TRINITY COLLEGE, DUBLIN,
"12th May, 1871.

"Dear Sir,—At your desire I have made a careful analysis of a specimen of your Extract of Malt, and, though unable to speak from experience of its action as a therapeutic agent, I am now in a predicament to put you in possession of its exact constitution.

"It is a liquid, of the colour such as genuine Extract of Malt ought to have, perfectly transparent, and having the specific gravity of 1.005. It is slightly acidulous, somewhat sweet, and has a taste such as might be given it by vegetable tonic substances. It has undergone a certain amount of fermentation. In 100 parts, by weight, it consists of:—

Water	71·88
Alcohol	7·54
Saccharine Matter	9·12
Azotized or Proteinic Compounds	4·40
Non-azotized Vegetable Extract	6·50
Ash	0·56

100—

“Of these constituents the most remarkable are those which include Nitrogen, the amount of which is unusually large—reaching as it does nearly 5 per cent. The Proteinic compounds in an ounce of it weigh 22·32 grains, and the analogous compounds in an ounce of beef-steak 98·43 grains. Hence, weight for weight, the alimentary value of the Extract is very nearly one-quarter that of the beef-steak. It is, therefore, nutritious in a high degree, and being no doubt easy of assimilation, it must constitute an useful supplementary food in cases of debility and weak indigestion.

“To John Evans, Esq., M.D. “JAMES APJOHN.”

“This pure preparation of malt, combined with the aromatic bitter of the hop, possesses in a most remarkable degree the elements admirably adapted for yielding nutrition to persons of constitutional debility, or of low vital power.

“Its use has been accompanied with decided benefit in asthma, bronchitis, consumption, atrophy, indigestion, (especially when accompanied with nervous irritability), and in stomach coughs.

“It is a highly nutritive tonic, and, from the process of fermentation through which it has passed, the starch has been converted into glucose, and is thus rendered perfectly digestible, and most suitable for building up the waste tissues, and invigorating the frame.”

Although this malt extract does not strictly come within its term of a farinaceous food, such a preparation is almost identical with the one previously examined—namely, Mellin's. Except that this and similar ones are liquid, and contains alcohol produced by allowing them to undergo a partial fermentation, and are, therefore, not suited for children. They are supposed to be modes of giving nutrition to invalids in an assimilable form, combined with a stimulant and tonic.

Evans's malt extract is sold in bottles containing 12 oz. fluid at 2s.

The specific gravity was 1·059.

It contained :—

Extractive Matter	20·6 per cent.
Proof Spirit	18 ”
Ash, consisting of Phosphate of } .47 ”	
Potassium, &c.	

The extractive consists of sugar and dextrine, 9·4, nitrogen, 4·1.

This preparation seems to be a pure fermented infusion of malt of the most concentrated form—flavoured with some aromatic bitters. It is, in fact, rather curious to see a fermented liquid of such a body. It has the dark amber tint of infusion of malt, and seems pure and genuine.

HOFF'S MALT EXTRACT.

“For obstinate coughs, bronchitis, asthmatic affections, and disorders of the chest and lungs, it is to be taken at breakfast time in the morning, and before going to bed, after well warming and frothing it, with the addition of a piece of sugar. It may be taken cold during the day. The dose on each occasion is a wine glass full ; for children one-half that quantity.

“For stomach and bowel complaints, impaired digestion, hæmorrhoids, &c., it should be taken cold and unmixed, either a little before or during the meal. The dose in these cases is the same.

“During the time the malt extract is used, everything, fat or acid, as well as spirits, have to be carefully avoided.” The specific gravity at 23·6 was 1022·5.

It contained :—

Extractive Matter	8·06 per cent.
Proof Spirit	7·2 ”
Ash, consisting of Phosphate of } .14 ”	
Potassium and Chloride of }	
Sodium	

The extractive contains sugar and dextrine, 3·5, and nitrogen, 1·4, and other extractives. The fluid was made with high dried malt from its containing caramels, and being black like porter. In fact, it bears a wonderful resemblance to ordinary porter, flavoured with absinthe or some other bitters. The amount of extractive is not equal to what would be found in Guinness's XXX porter.

REGISTERED FOR TRANSMISSION ABROAD.

THE

MEDICAL PRESS AND CIRCULAR

is published simultaneously in London, Dublin, and Edinburgh, every Wednesday morning. Price 5d. Post free, 5½d.

POST FREE TO ANNUAL SUBSCRIBERS £1 2 6
 ” IF PAID IN ADVANCE 1 0 0

. Post-office Orders and Cheques to be drawn in favour of—
 A. A. TINDALL, 20, King William Street, Strand, London, W.C.
 A. H. JACOB, Molesworth Hall, Molesworth Street, Dublin.
 MACLACHLAN and STEWART, South Bridge, Edinburgh.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIÈRE, Publishers to the Academie de Médecine, Paris—post free in advance £1 6s. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLMER and ROGERS; Baltimore, by Messrs. KELLY and PIRT; Philadelphia, by Messrs. LIPPINCOTT and Co., and Dr. BUTLER, post free in advance, £1 6s., about six and a-half dollars; or direct from the Offices in this country for the same amount, by the new Post-office Order system.

The Medical Press and Circular.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, JULY 31, 1872.

THE BRITISH LUNACY REPORT.

THIS important blue book was published last Thursday, and we proceed to extract a few notes from it. There are no less than 180 asylums, hospitals, and licensed houses for the reception of the insane in England and Wales ; and at the beginning of this year there were 58,640 persons detained therein, of whom 51,998 are classed as pauper lunatics, these numbers showing a considerable increase on the previous year. The private patients increased during last year in county and borough asylums by 18 ; in registered hospitals by 57 ; in licensed houses by 47 ; in naval and military hospitals by 41 ; and as “single patients”

in private charge by 28 ; while there has been a decrease of three in this class at the Broadmoor Criminal Asylum. The pauper patients increased in county and borough asylums by 644 ; in registered hospitals by 31 ; in Broadmoor Criminal Asylum by 32 ; in workhouses by 1,447 ; and as out-door paupers by 105 ; while the number of this class in licensed houses has decreased by 562. The county and borough asylums number 54 ; registered hospitals, 16 ; State asylums, 4 ; metropolitan licensed houses, 41 ; provincial licensed houses, 65. The total admissions of certified patients (12,573) are largely in excess of those of the year 1870, when they were 11,620. The increase, however, is not solely due to fresh admissions, but is owing in a great measure to the fact that a much larger number of patients were transferred in 1871 from certain asylums and licensed houses to other asylums. During last year, 219 workhouses were visited, containing (including the Metropolitan District asylums at Leavesden and Caterham), 9,738 patients, showing an increase of 2,043 upon those seen the previous year. Generally (the Commissioners observe), the reports were of a favourable character. The larger workhouses, and those having lunatic wards, are visited by one or more of the Commissioners annually, when insane inmates are examined, the question of their fitness for workhouse or asylum treatment considered, and the arrangements for their proper care and accommodation not only fully inquired into, but reported upon to the Local Government Board. To a very great extent many of the workhouse wards are used as asylums. During the past year upwards of 2,500 patients were seen in 17 of the larger workhouses alone, each containing more than 100 patients, and one, the New Manchester, as many as 275. The Commissioners still continue to have frequent occasion to direct the attention of the guardians to the importance of giving the insane in workhouses a more liberal dietary and a larger amount of animal food than is allowed to the ordinary inmates ; and also, whenever there are separate wards for this class, of providing a sufficient number of paid attendants to take charge of them.

Several deaths from injuries or violence occurred in county and borough asylums, and in licensed houses, during the past year, in all of which full inquiries have been instituted by the visitors or the Commissioners, as well as by the district coroners. Eighteen men and 13 women, were dismissed for various acts of cruelty or harshness to patients ; 21 men and 3 women for intemperance ; and 43 men and 23 women for various other offences, unfitting them for the responsible situations they held, such as insubordination, immorality, neglect of their duties, theft, and absenting themselves without leave.

The numerous changes which take place in the attendants both in public and private asylums, observe the Commissioners, has frequently been commented upon by us, and affords abundant evidence of a defective system urgently calling for attention on the part both of the governing bodies of public, as well as proprietors of private asylums. The proportion of day attendants to patients, although varying considerably in public asylums, is found to be as a general rule sufficient, but in most the night supervision is totally inadequate, large asylums, such as Stafford, containing upwards of 500 patients, having only one night attendant in each division. This we consider to be quite inadequate, more especially as the practice of placing attendants to sleep in dormitories which prevails in licensed houses is not, as a general rule, carried out in

county or borough asylums. In large asylums having infirmaries a special night attendant is obviously required for the proper nursing and care of the sick and dying ; and yet in many instances these patients are left to the uncertain, and often unfrequent, visits of the ordinary night attendant. So, likewise, we think it of the utmost importance in all asylums that arrangements should be made for the more efficient night care of the epileptic patients, and also those having known suicidal propensities.

The large number of epileptics in asylums who are found dead in bed, remark the Commissioners, and the frequent occurrence of suicides during the night, have induced us for some time to recommend special arrangements, and the appointment of night attendants exclusively for these classes ; the only means, as we believe, whereby accidents amongst them can be effectually guarded against. In some of the new asylums, and in several of the old ones, these arrangements have been carried out.

THE SMALL-POX HOSPITALS.

THE Committee of the Managers of the Metropolitan Asylum district have just issued a most valuable report with statistics as to the cases of small-pox treated in their several hospitals during the small-pox epidemic of 1870-71-72. The following are briefly some of the conclusions arrived at by the committee from the data furnished by carefully prepared statistical tables, viz,—11,174 cases reported as vaccinated have been treated, of which 6,169 were males and 5,005 females ; 3,634 unvaccinated cases have been treated, of which 1,884 were in males and 1,750 in females ; that the rate of mortality in vaccinated cases has been 10·15 per cent., in unvaccinated 44·80, the per centage in both classes being higher in the males than among the females. The death rate in the whole number has been 18·66 per cent., but of 2,763 deaths 394 occurred within forty-eight hours after admission. If these are subtracted, the average rate of mortality is 16·4 per cent., including children under 5 years of age. The Committee observe that much has been said by the opponents of vaccination upon the fact that the vaccinated cases received into the hospitals are three times as numerous as the unvaccinated cases ; but, for this to be of any importance, it ought, at the same time to be shown that the number of the vaccinated population is not more than three times the number of the unvaccinated ; so far, however, from this being the case, it is estimated that, even previously to the commencement of the present epidemic, the vaccinated were about nineteen times as many as the unvaccinated ; that the proportion of children under 10 years of age was 8·79 per cent. of the whole number of vaccinated cases, and 43·56 per cent. of the whole number of unvaccinated cases ; that between 10 and 30 there were 73·96 per cent. of vaccinated cases, and 42·39 per cent. of unvaccinated cases ; and that the percentage of deaths among the vaccinated children under 10 was 8·63 of the whole number of deaths, and among the unvaccinated 49·45 per cent. Whilst the admissions between the ages of 10 and 20, of vaccinated cases were 40 per cent. of the whole number admitted, the deaths were 20 per cent. of the whole number of deaths, showing the chances of recovery to be about twice as great as the chances between 20 and 30, when the death rate was 36 per cent. and the proportion of admissions 35 per cent. The mortality,

which in unvaccinated cases was no less than 47.5 per cent., and in badly vaccinated cases 25 per cent., varied in well-vaccinated cases from 5.3 in those showing one good mark, to 1.1 in those showing four or more good marks; and that of the total of 620 well-vaccinated cases under 15 years of age, the death rate was only 0.47 per cent., giving a comparative immunity from fatal results.

More males than females have been treated (the numbers being 8,053 males and 6,755 females), and the percentage of deaths in the former has been higher than in the latter, viz., 19.50 males, and 17.64 females. The reasons given by Dr. Grieve for this are the extra wear and tear undergone by the man, his more irregular habits (which unfit him to cope with the disease), and his occupation generally bringing him more into contact with the disease. The differences in the numbers and in the death rates of the two sexes arise chiefly in adults. Up to 20 years of age the numbers admitted were 4,112 males and 3,803 females, and the death rate was nearly the same—17.9 per cent. males, and 17.6 females. The average duration of treatment of a well-vaccinated case is about 21 days.

The following suggestive remarks conclude the report:—

“The necessity of re-vaccination when the protective power of the primary vaccination has to a great extent passed away, cannot be too strongly urged. No greater argument to prove the efficacy of this precaution can be adduced than the fact that out of upwards of 14,800 cases received into the hospitals, only 4 well-authenticated cases were treated in which re-vaccination had been properly performed, and these were light attacks. Further conclusive evidence is afforded by the fact that all the nurses and servants of the hospitals, to the number at one time of upwards of 300, who are hourly brought into the most intimate contact with the disease, who constantly breathe its atmosphere, and than whom none can be more exposed to its contagion, have, with but few exceptions, enjoyed complete immunity from its attacks. These exceptions were cases of nurses or servants whose re-vaccination in the pressure of the epidemic was overlooked, and who speedily took the disease; and one case was that of a nurse, who, having had small-pox previously, was not re-vaccinated, and took the disease a second time.”

Notes on Current Topics.

Hypertrophy and Lengthening of the Femur and Tibia in a Case of Syphilis.

At a late meeting of the *Société Médicale des Hôpitaux*, M. Guibout exhibited a patient from one of the wards of Saint Louis, suffering from tertiary syphilitic ulcerations, whose right leg had undergone considerable lengthening. Both femur and tibia were found to share in this lengthening, which amounted to at least two-thirds of an inch. M. Guibout remarked that hyperostoses are, as a rule, confined to a limited portion of a bone, but that in the case of this patient, two entire bones exhibited throughout a well-marked hypertrophy, as manifested by their increased thickness as well as length, showing that under the influence of a syphilitic diathesis as in case of scrofula, the process of nutrition and growth may be inordi-

nately stimulated, inducing hypertrophy of the bones, without deformity. M. Bergeron had seen an analogous hypertrophy of the bones of the leg in the case of a scrofulous patient.

Hydrate of Chloral.

From the third edition of the work on this drug by Professor Oscar Liebreich, we gather that in his opinion the action of hydrate of chloral depends upon the formation of chloroform in the blood. When administered in appropriate doses, it produces in the course of 10—20 minutes a natural sleep, which comes on quietly and lasts from four to ten hours. After awaking, the patient may continue in a drowsy state for several hours, but when this feeling has disappeared, no other unpleasant after-effect is experienced. On the contrary, one usually feels refreshed, as after an ordinary night's rest. The sleep produced, then, by this hypnotic, differs in no respect from the natural physiological sleep. If the sleeper is aroused, perfect consciousness is at once restored. The pupil of the eyes, which contracts during this sleep, is dilated again when the individual awakes, as in the case of normal sleep, but differing in this respect from the sleep produced by opium.

Both the circulation of the blood and the respiration are retarded during the sleep induced by chloral, but not more so than in the case of ordinary sleep. Chloral interferes in no way with the process of digestion, tending rather to stimulate the appetite. In exceptional cases only is vomiting induced. The temperature of the body does not seem to be influenced by its use. Congestion of the brain, such as is sometimes produced by opium, has never been observed to follow the administration of chloral. The anti-spasmodic effect is produced only by comparatively large doses. As an anodyne, also, large doses are required. As a sure anæsthetic, too, it is effective only in very large doses, such as may be followed by serious results, so that it is not to be recommended for this purpose.

The administration of chloral is therefore indicated in all cases of sleeplessness, whether attended by fever or not. It may be given advantageously in all cases of convulsions, especially those depending upon some lesion of the central nervous system, without regard to the acute or chronic character of the affection. As an anodyne in neuralgic affections, in the lancinating pain of cancer, and the like, its value is rather doubtful. In these cases it seems to be more efficacious when administered in connection with morphine. Chloral, owing to its pungent, acrid taste, is contra-indicated in all affections involving the destruction of the mucous membrane of the *primæ viæ*. If given at all in this case, it should be in the form of an enema, or else largely diluted with water. It should not be given in arthritis. In typhoid fever, and in all diseases of the heart, it should be administered with great caution, and in very small doses. In hysteria it seems to induce the convulsions accompanying this affection, and its use is therefore contra-indicated.

The Cost of a Bottle Cover.

ANY of our readers, who have been also readers of the *Pharmaceutical periodical*, will recollect the interminable series of law battles which took place a year ago over the

tin foil capsules which are largely employed for hermetical sealing of bottles. Mr. Betts claimed sole patent rights in these capsules, and instituted chancery suits against a dozen different druggists who used similar appliances not made by him. After litigation, only exceeded in extent and expense by the Tichborne case, Mr. Betts was beaten, and has had to pay the whole of the taxed costs, and he must have been a wealthy man if his finances have survived the depletion. We observe that even after he has done so a little balance of £700 remains due to the attorney of the victorious party—being the margin between the taxed and untaxed costs, and the defendants, although they remain in possession of the field, are losers to that extent.

We should be interested to know whether the capsules will ever pay their own lawyer's bill.

Novel Method of Taxis.

A MOST extraordinary case, but one which has important therapeutic relations, is reported by the *Gazette de San Francisco*. A prisoner at San Rafael was attacked with intestinal strangulation and stercoraceous vomiting, Dr. Taliaferro, chief surgeon to the prison, regarded the case as hopeless, and left, when W. Lebrun, the student in attendance, determined if possible to falsify this prognosis by an original method of treatment, which happily met with complete success. He injected into the rectum a solution of carbonate of soda, and after it a solution of tartaric acid, and by a forcible pressure on the anus with a sponge, prevented the evacuation of the gas caused by the effervescence. Three such injections were repeated, one after the other, with which four ounces of carbonate and eight grammes of tartaric acid were used. The rapid distension of the large intestine appeared so beneficial, that the strangulation was reduced, and an abundant evacuation took place. The patient was cured, but a subsequent attack of parotitis with suppuration caused death.

Competency of Surgeons to Act as Apothecary.

CHIEF JUSTICE WHITESIDE has given utterance last week to a ruling which is of much interest and some importance to the Profession in Ireland.

At the Meath Assizes application was made on behalf of Mr. Daignan, a ratepayer, that a sum of £7 10s., allowed by presentment to Dr. Nicholson, surgeon to Trim Jail, for compounding medicines, be disallowed. The Board of Superintendence had elected Dr. Nicholson as a duly qualified surgeon, but not as an apothecary, and counsel contended that he was not entitled to receive the amount in question, not being a duly qualified apothecary.

Dr. Battersby, Q.C., contended, *contra*, that the board were justified in paying their surgeon the additional sum.

His Lordship said that in this case he should hold the objection raised on behalf of the ratepayers to the claim of Dr. Nicholson to be a sum of £35 for the salary of the surgeon, but had added the disputed presentment—a sum of £7 10s.—for compounding medicine; and the question for him to consider was, whether the latter sum could be allowed. He was of opinion that it could not. It was clear that according to the Act of Parliament—the 7th Geo. IV., ch. 74, sec. 72—the offices were different, and that the apothecary was not permitted to do more than

administer the medicine, but not to advise as a physician or act as a surgeon. He was, therefore, of opinion that a surgeon was not entitled to receive any compensation for dispensing medicine, and that the presentment was void, because the section under which it was alleged to have been made had not been specified.

Dr. Ritmann on Prostitution.

IN the *All. Wien. Med. Zeit.*, 9th July, Dr. Ritmann continues some observations on professional prostitution which he has been making in previous numbers of that excellent journal. "I was," says our author, "myself a witness in Hamburg how at every hour of the day the alluring of men into the tolerated houses goes on in the most shameless way, and I saw a tired European wanderer thrice in one day allured by various pretexts into such houses, when the poor man, whose time of life had arrived at its frigid period, was each time turned out again with contemptuous laughter by the inmates. I see in police houses of this kind (he continues) nothing more than pattern taverns of completely professional prostitution and just as little as we should expect that only healthy persons should be found outside of our magnificent hospitals—or that only quite intelligent people should be found outside of our lunatic asylums—or only honest people outside the walls of our prisons, &c.—just as little shall we expect by means of such houses, that modesty will be found enshrined outside of these prisons and their infamous walls. The difference between hospitals, lunatic asylums, and prisons, on the one side—and police bordels on the other—only consists in this, that in the first institutions we endeavour to free men from their diseases; in the last, on the other hand we provide by police means for the coming evil, and whatever good police regulations may do, it is a hundredfold over-weighted by the disadvantages which accrue to a state, which makes concessions to a privileged police-managed professional prostitution." Our author remarks that in his professional capacity he has noticed that the inmates of such houses in Vienna are almost always orphans or foundlings, or daughters of persons who have come down in the world. In ancient Rome, such children were legally devoted to prostitution, and modern policemen seem to wish to revive this ancient custom. "If the police of prostitution suppose that statistics prove that violation and lewdness are removed by bordels, their idea is erroneous, for violation and lewdness of the most coarse description are far more frequent among country populations than in large towns."

Intra-Uterine Stem Pessary, &c.

AT a meeting of the Gynæcological Society of Boston, Dr. Ingham showed a new kind of intra-uterine galvanic pessary, made of very slender coils of zinc and copper wire twisted upon each other, and mentioned that he had used this in a few cases of obstinate menorrhagia occurring in a sub-involved uterus, with great benefit. Dr. Blake liked galvanic stem pessaries, but was inclined to prefer the current more directly applied. Dr. Storer was glad to see that so much interest was shown in the intra-uterine application of galvanism. He exhibited apparatus to show that he had devised plans for treating the cavity and cervix of the uterus many years before. Dr. Newman related a case of operation for ovariectomy, with-

out anæsthesia. The operation lasted twenty-five minutes, and the pain was but trifling, and little greater than what she had experienced when tapped on previous occasions. Dr. Brown mentioned a visit he had paid to the New York State Women's Hospital, and mentioned that Dr. Emmet's operations are chiefly carried on by scissors, instead of the knife. "One of the first things that strikes an observer," says Dr. Brown, "is Dr. Emmet's substitution of scissors for the knife, the latter being very rarely used in his operations. The advantages claimed are—less risk of subsequent inflammation, a smaller loss of blood, and a gain of time. Experience has demonstrated that where the pelvic tissues are clipped with scissors, lacerated by hand, or gnawed with the *écraseur*, the risk of inflammation following is reduced to a minimum. It is a fact somewhat difficult of explanation, but still it is a fact that inflammation is much more likely to follow the use of the knife in the pelvis than of any other methods just mentioned. There can be no reasonable doubt that less hæmorrhage is attendant upon the use of scissors than the knife—a circumstance often of great service to the operator, as well as saving to the patient. Since the publication of Dr. Emmet's work on vesico-vaginal fistula, in 1868, I have used scissors in numerous minor operations, and am fully satisfied that the hæmorrhage is less. The freshening of the edges of a fistula can be done in about half the time with scissors, with a greater certainty, leaving no part of the surface undenuded."

Glucose in Healthy Urine.

DR. HUIZINGA (*Bull. Soc. Chim.*) uses tungstic and molybdic acids, in testing for the presence of sugar in urine. When tungstate of sodium is boiled with a liquid containing glucose and with the addition of a little potash, and when a little hydrochloric acid is added, the liquid takes a bluish colour, which disappears if excess of acid be added. Molybdic acid behaves in a similar manner, but the blue colour is more stable. The liquid is acidified by hydrochloric acid, molybdate of ammonium added and boiled; if the solution contain grape sugar, there is a bluish tinge formed. The author has thus been always able to find sugar in human urine as also in that of dogs and rabbits.

A Lady House Surgeon.

THE first appointment of a lady doctor as officer of a public hospital has taken place at Birmingham, where Miss Louisa Atkins, holding the degree of M.D. after five years' study at Zurich, has been appointed resident Medical officer and secretary to the Birmingham and Midland Hospital for Women. How about registration? The holder of such an office ought surely to be registered. We have no wish to depreciate the course of study of the lady in question, but we think the law requires all such officials to be registered.

Medical Man Frozen to Death.

THE heat of the summer need not make us quite forget the terrors of the winter. Those desirous of assisting and able to do so may be reminded that an appeal is being made to the members of the Medical Profession and their friends on behalf of the widow and

three children of the late F. B. Eaton, surgeon, Nuneaton, who was frozen to death on the night of the 27th of November last.

The late Dr. Eaton being in pecuniary difficulties at the time of his death, the widow and children were left without any resources, so that the circumstances of the case are peculiarly distressing; especially as the children are all girls, consequently they cannot be admitted into any Medical school, and their tender age (all being under two years and a-half old) renders it impossible for the widow to do anything towards her own maintenance.

The following gentlemen will bear witness to the facts:—

The Rev. W. S. BUCKNOLL, M.A.
T. BLAND, Esq., Solicitor.
R. B. NASON, Esq., M.R.C.S.
A. K. ROBINSON, Esq., M.D.

References will be answered, and subscriptions received, by Mr. T. J. Craddock, The Poplars, Nuneaton. The deceased was a Freemason in the Nuneaton Lodge.

Hydropathic Establishment in Italy.

IN the *Independent*, 5th July, we have a notice of the Hydropathic Establishment of St. Vincent, which, it seems, is amply furnished with all the apparatus used in hydropathy, warm baths, simple and medicated baths, an ample swimming bath, and perineal baths for affections of the bladder. Treatment is directed by Dr. Carloti. The salubrity of the air and beauty of the climate and neighbourhood constitute a powerful aid to treatment. The establishment will contain eighty persons. This establishment is not far from Turin, and we doubt not, will be frequented by some of our Anglo-Italians.

Lunacy in Cheshire.

IN the Annual Report of the Chester County Lunatic Asylum before us, we find some interesting statistics and remarks by Dr. Davidson, the Medical Superintendent. The county of Cheshire is happily low down in the scale of lunacy, the proportion being only 1.79 per 1,000 of the population. During the year 64 patients were discharged cured; of these, five-sevenths had been brought to the Asylum during the earlier stages of the maladies, thus proving, as Dr. Davidson remarks, that the sooner patients are brought under the influence of therapeutic and moral agents the greater are their chances of recovery. There were fifty deaths during the year; of these 35 were males, 15 females. The disparity in the proportion of deaths in the sexes is mainly owing to the prevalence of general paralysis among the males, which is a disease considerably less frequent among women.

Excessive indulgence in alcoholic stimulants ranks again as the most prominent on the list of causes; an evil which the House of Commons has, during the past week, set about with real earnest to remedy.

Death of Dr. Curran, of Dublin.

WE announce with regret the death of Dr. Henry Curran, which took place on Thursday, at his residence, 13 Blessington Street, Dublin. Dr. Curran was one of the physicians to the Mater Misericordiæ Hospital, a teacher in the Carmichael School of Medicine, and one of the Medical officers of the Blackhall Street Dispensary. Some

months ago he had a severe attack of typhoid fever, from which he never completely recovered, and, like many others of his noble Profession, he may be said to have fallen a victim to his exertions for the relief of the poor.

Postal.

HAVING incessantly remonstrated with the Dublin Postal authorities on the complete inefficiency of their Returned Letter Department without achieving any instalment of a remedy for the grievance, we publish the following from a provincial newspaper in the hope that the hint may be more persuasive than our own supplication:—

"CAUTION TO POST-OFFICE OFFICIALS.—Our subscribers and ourselves are put to serious inconvenience and loss by our papers being purloined whilst passing through the post-offices. Papers upon which we have put private marks, and posted in Ennis—and which, we have no manner of doubt whatever, have been despatched from Ennis—have not reached the subscribers to whom they were addressed, though they had only to go through one other post-office. Any official in a post-office, or letter carrier, purloining a newspaper—which is private property—would, if detected, be liable to transportation; and if we show that we strongly suspect any one post-office our means of punishment is short and sure. So much for the present!"

Dundrum Lunatic Asylum.

WE have authority for stating that the announcement of the name of Dr. Joseph Hatchell, Resident Medical Superintendent of the Maryboro' Lunatic Asylum, amongst those of probable candidates for the appointment rendered vacant by Dr. Corbet's death, was an error. Dr. Joseph Hatchell has never been an applicant for the vacant office.

Irish Military Medical Movements.

DR. DANE, Inspector-General of Hospitals in Ireland, has retired upon half-pay.

Staff Assistant-Surgeon Connolly has been ordered to proceed to Navan, to take Medical charge of the troops stationed there.

Staff Assistant-Surgeon Holmes will accompany the men of the Army Service Corps ordered from Ireland for the Autumn Manœuvres.

Staff Surgeon Hardinge takes Medical charge of the men of the Army Service Corps at Aldborough House and Portobello Barracks.

The Jefferson Medical College.

A LARGE endowment fund is being raised for the New College and Hospital Buildings for the Jefferson Medical College in America, and a large legislative appropriation is expected.

Lunacy Certificates.

IT has always been a favourite fallacy of the uneducated that lunatic asylums are, as often as not, receptacles for the incarceration of some persons whom it is desirable to get out of the way. It would appear that, if there be none, there might, under existing law, be some truth in this idea, and while, at the present moment, Parliament is legislating for the control of habitual drunkards, it would be worthy of inquiry whether the present system of certifying lunatics is as safe and perfect as it might be, and

whether it is not—while troublesome and intricate in cases of real urgency—too lax to afford a perfect check against abuses.

Mr. Baron Cleasby was occupied for two days in trying an action in which Mr. Walker, an upholsterer, claimed from the Nottingham Board of Guardians £500 as damages for his illegal detention in the imbecile ward of the Nottingham Workhouse. It was shown that on the 14th April, a man named Pilkington, a relieving officer of the Nottingham Union, called at his house and induced Mr. Walker to get into a cab and go along with him. The relieving officer then conveyed Mr. Walker to the Nottingham Workhouse, and he was detained there. On the following morning the plaintiff was placed among a number of people in different stages of insanity; his clothes were taken from him, and he was ordered to put on a dress which was used for lunatics in the workhouse, and which, in this instance, had been worn by lunatics before, and was not in a very cleanly state. In this condition the plaintiff was detained from the 14th to the 25th April, although on his arrival he had been reported sane by the Medical officer of the Union. The plaintiff, in his examination, said—"I was fed very badly indeed. The breakfast was half a slice of bread, and what they call tea, but which was milk and water. At dinner there was half a slice of bread, potato, and one and a half ounces of meat. I had not enough food, and lost a stone and a half whilst there. At the end of ten days I was taken before a committee. I was then in the same dress that I had on in the ward. I was asked a few questions by them, and was ultimately told to take my discharge." Mr. Seymour (for the Guardians) said the plaintiff's wife, frightened for her husband's safety, applied to Dr. Stanger, and from him received the following certificate:—"13th April, 1872. I certify that I have this day seen Mr. George Walker, of Lister Gate. He is subject to uncontrollable fits of delirium, and the life of his wife is in jeopardy while he is under their influence. It is very necessary that he should be at once placed under restraint."

It would certainly appear that if it should be proved that the plaintiff was sane when he was locked up with a ward full of pauper lunatics, he had a good claim for slashing damages. The result proved once again the glorious uncertainty of the law, for the jury awarded him three pounds.

The Quekett Microscopical Club.

THE seventh annual meeting of this club was held on Friday at University College, when the retiring president, Dr. Lionel S. Beale, F.R.S., gave his valedictory address. This club, which was established to afford young microscopists that assistance in working out the various details of microscopical science which only association with the more experienced can give, now numbers over 540 members, and its career has been attended by unprecedented success, and its results have been satisfactory in the extreme. The new president is Dr. Robert Braithwaite, F.L.S. The four vice-presidents are Dr. L. S. Beale, F.R.S., Mr. Arthur E. Durham, F.R.C.S., Mr. Henry Lee, F.L.S., and Dr. Matthews. The four vacancies on the Committee have been filled by Mr. John Fagpen, F.R.M.S., Mr. B. D. Jackson, Mr. Fred. Oxley, and Dr. Ramsbotham. The following gentlemen have been re-elected to serve during the ensuing year:—As hon. treasurer, Mr. Robert

Hardwicke, F.L.S.; as hon. secretary, Mr. T. Charters White, M.R.C.S.; and as hon. secretary for foreign correspondence, Mr. M. C. Cooke, M.A.

The St. Louis Operation for Vesico-Vaginal Fistula.

At the late meeting of the American Medical Association, Dr. Pallen exhibited the instruments, and described the method, employed in what has come to be known as "the St. Louis plan" of operating in vesico-vaginal fistula. Not every one had the skill or the opportunities of a Sims, or an Emmet; it was desirable, therefore, for the majority of the Profession that the operation should be simplified as far as possible.

The instruments exhibited were these:—1. *Scissors*, for paring the edges of the fistula. There are several pairs of these, some straight, others bent flatwise, near the pivot, at various angles, so as to operate with the greatest convenience upon a wound in any position. The special peculiarity of these scissors is that they have but one cutting edge, which is opposed to a square edge of softer material. This is to insure the opposition of the blades so necessary to trimming smoothly the often indurated tissues. They are the invention of Mr. Leslie, an instrument maker of St. Louis. 2. *Needles*, which are the finest cambric sewing needles ground to trocar points. These are threaded with fine but strong silk, doubled so as to make a loop without a knot, through which may be passed the small end of (3.) the *suture wire*. This is made of moderately large silver wire, sand-papered to extreme thinness at one extremity, so that its small end, even when doubled through the loop of silk, is no thicker than the fine needle used. The object of this is to allow the wire to follow the thread with perfect ease, while, as it is drawn through, its larger portion plugs up the hole made by the needle so as to prevent any bleeding. 4. The *needle-holder* requires no special mention. 5. The *suture-gauge*. From a handle extends a shaft of flexible copper, terminating in a flattened extremity. This flattened portion has a base next the shaft perhaps five-eighths of an inch broad, while its apex is about one-eighth of an inch. It does not taper gradually, but by three or four opposed rectangular notches. This gauge, and we believe also the tapered wire, were invented by Dr. Hodgson. 6. *Forceps*, for seizing and twisting the wire.

In paring the edges of the fistula it is often advisable not to take away the rejected tissue piecemeal, but to remove it as a complete ring, since thus it can be more easily held. The wire having been drawn through both flaps nearly to its thick extremity, it is cut off at the proper length, and the edges of the wounds are approximated to the exact degree at which it is desired they may be permanently retained. The suture-gauge is then placed flat upon them in such a manner that it shall just touch the wire on either side at its points of entrance and emergence. The ends of the wire are next seized by the forceps, and twisted as firmly as possible down upon the gauge, which securely protects the tissues from injury. The gauge is now removed, and the relaxation consequent upon this gives sufficient room for swelling. It may be mentioned that if the same wire is used for more than one suture it should be freshly annealed in a candle flame every time it is passed.

In fissures of the neck of the uterus, so common after parturition, the fine needles above described were found to pass with the greatest ease through the hard tissue of the part; and such was the facility with which the edges of the fissure might be at any time approximated by the aid of the suture-gauge, that the speaker was accustomed to allow his patients to walk about immediately after the operation.

Out of 153 candidates for the M.R.C.S.E. only 24 were unlicked—a decided improvement.

ONLY 1,467 deaths were registered in London during the past week, being 144 below the average.

HIS ROYAL HIGHNESS THE PRINCE OF WALES has graciously consented to become the patron of the Hospital for Diseases of the Throat.

A MEDICAL College has been organised at Wilmington, North Carolina, under the title of the College of Physicians and Surgeons.

It is announced that M. Ricord will be present at the Meeting of the British Medical Association, and will deliver an exposition of his views on the subject to which he has specially directed his attention.

WE have satisfaction in announcing that the progress of Dr. Macnamara, of Dublin, towards convalescence is so satisfactory that it is hoped he will shortly be able to resume his professional avocations.

DR. BROWN-SEQUARD was lately married to a young lady in Cincinnati. He will return to France shortly, but is expected again to return to America in September, when he will deliver a course of lectures at the Harvard Medical School.

DR. PITCHER, an eminent Physician of Hudson, N. Y., died May 31, from the effects of poison introduced into his system while performing a *post-mortem* examination on a subject who had died from erysipelas a few days previous.

ON Friday last Lord Gifford pronounced an interlocutor finding that Miss Jex Blake and the other lady students at the University of Edinburgh are entitled to complete their full Medical curriculum, and to graduate on the same footing as male Medical students.

BY the last return, the total number of paupers in the metropolitan district was 102,333, of whom 31,820 were in the workhouses, and 70,513 received out-door relief. Compared with the corresponding weeks of 1871, 1870, and 1869, these figures show a decrease of 18,045, 24,981, and 21,746 respectively.

At a meeting of the new Glasgow Convalescent Home at Lenzie in connection with the Royal Infirmary held last week in the Secretary's office, Hope Street—Wm. Wilson, Esq., chairman—D. P. Stewart, M.R.C.S.E., and William Whitelaw, M.D., F.F.P. and S. Glas, both of Kirkintilloch, were unanimously appointed joint Medical Officers of the Institution. In a month or two the Home will be ready for convalescents.

A SHIP with Scandinavian immigrants arrived recently at Wellington, New Zealand, having on board some cases of small-pox. Considerable alarm had been occasioned, as it would appear that the Vaccination Act has never been enforced in Wellington, and that the native population has never yet submitted to it. The Medical officer of the ship had been placed under arrest for having reported the disease as measles.

THE Secretary of State for India has, on the recommendation of the Secretary of State for War, decided that in future, British Medical Staff officers proceeding to or from India shall receive servant's allowance at the rate of 1s. 6d. a day, for one servant only, in accordance with the War Office Circular of the 23rd December, 1857.

THE *Medical Times and Gazette* states in its last issue that there will be no summer session of the General Medical Council this year. The Branch Medical Council for Scotland have just met, and given the *coup de grace* to the abortion which has been named the Scottish Scheme for a Conjoint Board. The Scottish Branch Council have declared by a vote that the whole thing is at an end, as far as Scotland is concerned. Our contemporary says:—"The conjoint 'practical examination' scheme we always considered as a sham, and a transparent one; but it has served its use as a show of compliance with the recommendations of the General Medical Council, to which no Medical authority in Scotland had ever the slightest intention of meekly submitting." We concur entirely with the *Medical Times* in its estimate of the Scotch scheme, and we look upon the attempt of the Scotch Licensing Bodies to retain the "Dutch auction" on which they have subsisted as conclusive reason for a prompt and decisive action of Parliament in their case.

Special Report

ON

DISEASES OF THE THROAT.

Edited for the "MEDICAL PRESS AND CIRCULAR."

By PROSSER JAMES, M.D., M.R.C.P.,

Physician to the Hospital for Diseases of the Throat and to the North London Consumption Hospital; Lecturer on Materia Medica and Therapeutics at the London Hospital.

(Continued from page 31.)

BEFORE proceeding further, I am desirous of expressing my sincere thanks for the courtesy already extended to me in reference to these Reports, and my regret that their design should have been in some cases misunderstood.

Each Report was intended to be an incomplete one, so that from time to time additions might be made as new material came under notice. It was, moreover, not intended to attempt any classification of the material, but merely to collect a series of paragraphs on the whole range of diseases of the throat. The use of these would be to serve those who might be investigating the literature of the subject, or engaged in the practice of this branch of our art.

The favourable reception of my perhaps rash promise induces me to attempt rather more than was proposed. It seems that by some correspondents I am expected to give a clinical report on each subject separately. To some extent this shall be done, but it will perhaps cause a little delay. It will, however, be impossible altogether to abandon the design originally traced out, though in accordance with the wishes of some of my professional friends, one or two subjects will be taken up in the manner they suggest. One of the first of these is Laryngoscopy, as already announced. Originally, I proposed

merely to enumerate the various instruments employed in the diagnosis and treatment of diseases of the throat, stating as far as memory served the names of their inventors, and giving figures of those I preferred. The offer to lend some of their engravings by inventors and makers induce me to give more numerous illustrations, and as the artist has not completed some of the drawings of my own, I am obliged to postpone what was intended to appear this week. I therefore take the opportunity of reiterating my former offer to receive such suggestions and references as may be furnished me, with the thanks I now express for those already supplied. They cannot fail to be of use sooner or later, and if my correspondents will, so far as may be necessary, excuse me from writing a personal reply, they will add greatly to the obligation they confer.

I will only then repeat that the Reports will extend to all diseases involving the mucous membrane of the fauces, of the nose and mouth, of the larynx and trachea, of the pharynx and œsophagus. Notes on the mucous membrane generally may here and there be introduced. Croup and diphtheria, as well as syphilis, and other diseases in which this membrane suffers, will find a place in due course, and some forms of consumption cannot be excluded. But besides these, the diseases of each organ separately will be taken into account. The fauces, the larynx, the pharynx, and the posterior nares constitute, so to say, the subject of the reports.

Bronchocele and some other diseases will come forward, though perhaps at a later period. In the meantime, should authors or others send me notes and references in regard to any of these or allied topics, I can assure them they will be welcome.

P. J.

CONTRIBUTIONS TO THE PATHOLOGY OF THE BLOOD.

By PROF. S. STRICKER, of Vienna.

(Translated for the MEDICAL PRESS, by E. B. BRONSON, M.D., from the *Archiv. fuso Dermatologie und Syphilis*, II. Heft, 1872 (a).)

I UNDERTOOK the investigation here reported, in order to solve two questions. In the first place, I wished to ascertain the nature of the corpuscles discovered by Losterfer, and in the second place, I desired to learn for my own inspection whether these corpuscles occur as Losterfer has asserted, only in the blood of syphilitic persons.

I began my investigations with the blood from three syphilitic men, who were placed in succession at my disposal. In all three cases were the corpuscles in question to be seen in great abundance after several days of incubation, and thus for the first question, I believed that I had found ample material.

At this point, a preliminary question arose, which was, whether the corpuscles of Losterfer do not also occur in fresh blood.

Before entering, however, upon the reply, I will precisely describe the method according to which I prepare and preserve my specimens.

(a) The article appears also in the *II. Heft des Wiener M. Jahrbucher*, 1872.

Method.—When I prepare the blood preparation merely for the purpose of examining it in a fresh condition, and by the strongest magnifying power, I endeavour to make the preparation as thin as possible. This can be best done, first, if the glass slide be thoroughly cleaned and dried, and then if the covering glass, held with thumb and forefinger at two parallel sides, be touched at its central part to the fresh drop of blood oozing from the slight puncture, in such a manner, that on lifting the glass, a very minute drop remains upon its surface. Then the glass being quickly laid upon the slide, the small drop will usually spread itself out to a sufficient extent. If that be not the case, a gentle pressure upon the cover suffices to spread it sufficiently. Inasmuch as these examinations are always made with immersion lens, and moreover since it is desirable to come as near the edges of the object as possible, the overflow of water to the borders, however, rendering the preparation useless, the remark may not be superfluous, that I bring the water for immersion on to the covering glass, in the form of an exceedingly minute drop, by means of pipets thinly drawn out at both ends.

The appearances which we see in fresh blood are extremely multiform.

In the blood of many individuals one sees, indeed, only the well known form-elements, viz., red blood corpuscles, colourless blood cells, and smaller colourless granules. Very often, however, colourless particles appear from the size of an enucleus, to the average size of the nucleus of a colourless blood corpuscle. You become aware of their presence more especially in working with very high magnifying powers.

I will now describe the variety of forms of these bodies, as this can be of but slight value. In general, I will only remark that many of these corpuscles have the appearance as though they were bits of young cells, while others look as if they formed nodules of coagula. The latter occur mostly where the preparation is somewhat thicker, and in places free from blood corpuscles which are traversed by numerous delicate fibres. Hence the supposition that these fibres, as well as also the ramified nodules, are *fibrine* is not to be at once discarded. These and the particles looking like bits of colourless blood corpuscles as well, are mostly multiform in shape, but seldom spherical.

Where abundant fibrine-meshes occur, there are always present also large numbers of very fine granules. One can, however, easily convince himself that these are produced merely by the optical transverse sections of fibres which run parallel or oblique to the axis of the microscope.

Beside the elements described, there appear in the perfectly fresh blood of many individuals very small granules, with No 10 immersion lens, scarcely to be defined, which are frequently in lively oscillation.

Whether these oscillations are solely the so-called Brownian, or whether one has not to do with organisms sometimes, which show vital movements, I am unable to determine. It seems to me worth while, however, to call attention to the circumstance that the existence of very minute lower organisms in the circulating blood of healthy individuals is not excluded from discussion.

Concerning the occurrence of such bodies as may with certainty be recognised as adventitious bodies, each one will be able to satisfy himself who pursues the microscopic investigation of the blood in the proper manner.

There also occur, seldom to be seen, in fresh blood, corpuscles of which it is difficult to declare whether they are accidental admixtures, or whether they were also present in the circulating blood; they are mostly spherical, darkly contoured, and distinguished in that, when seen by high power (lens 15, Hiernach), and by exact adjustment they are quite dark.

The object to be attained in incubation for the purposes which I have here in contemplation consists in preserving a good preparation under access of air as long as possible. This object is attained when the preparation is kept in a space where, on the one hand, it is protected from drying up, and on the other, from admission of vapour. That drying is unfavourable to the culture is

to be comprehended at once. Almost the same holds good of the admission of vapour, of the dilution of the blood. The form elements of the blood are exceedingly sensitive to a dilution of the plasma in which they exist. The red corpuscles become pale, and the plasma takes up the colouring matter instead and becomes cloudy. I shall show later that the gradual admission of water is also in high degree prejudicial to the object which we have here in view. I can only state in general how both ends are to be attained—that is, so that the preparations do not dry up, and yet also do not take up water. The finer shades must each experimenter find out for himself. The preparations are to be put into a chamber in which relatively to the space of the chamber, an inconsiderable surface of water is offered. For an ordinary exsiccator glass as used by the chemists for drying, a wet sponge of the size of a walnut will suffice to protect the enclosed preparations from drying. Within the exsiccator glass I insert a stand, in such a manner that it will hold about a dozen preparations. The slides being provided with etiquets, preparations from different individuals may be placed in one glass and on the same stand.

For the purpose of culture I do not make as thin preparations as above described. Before I prepare the object I make upon the warmed slide two little ridges of wax, so that the cover may rest upon them. After preparing the specimen, I press the cover down upon the ledges of wax till the blood corpuscles adhering together in the form of rolls of money, are arranged in the form of a network. Within the meshes filled with plasma of this net-work are spaces for culture presented, which are excellently suited to our purpose.

For reasons to be given later it is expedient to make the preparation relatively to the covering glass so small, that the borders of the former can be examined with the immersion lens.

By such a condition of the preparation it is easy to test micro-chemically the granules within the field. The preparation will be changed into a relatively hard cake by means of the fibres of fibrin which traverse it; the granules themselves are frequently entangled in a texture of fibrin; one or more can be optically fixed while the re-agent in very small quantity is allowed to flow to it from the edge of the covering glass.

The significance of this method will be comprehended if one considers that in fresh and even in older thin blood specimens, every addition of fluid put forms the elements into motion, which by high magnifying power appears very rapid. If now any one wishes to convince himself how a certain granule is altered by the re-agent, it is necessary to try and follow it by a corresponding movement of the slide. But since the granule does not alone move, but the red corpuscles swim with it, the former is soon hidden, and hand and eye must both be kept actively in play in order to pursue the granule in its rapid course. At all events the judgment will never obtain that sureness which is possible when the granule lies at rest, and the re-agent operates upon it slowly. Especially if there be a number of corpuscles in a field near the edges of the preparation, and the re-agent be allowed to flow from the corresponding side of the cover, the reaction can be perceived as soon as the fluid reaches the specimen.

When it happens that I have to observe a certain spot or a certain granule several hours together, I build about the slide a wall of four slips of folded and moistened filtering paper. The paper is, from time to time, moistened from a drop-glass. In such a manner it is possible without difficulty to preserve the specimen 8 or 10 hours under the microscope.

I have obtained some interesting results by means of keeping the specimen several hours in observation upon the heated object table. For this purpose I affixed to the heating table (a) constructed by me a copper wire about 25 centimetres in length, and pushed a small spirit flame

(a) Stricker, Handbuch des Gelbelehre. Allgem. Methodik.

from the further end gradually towards the microscope, till the desired temperature was attained. I then wrapped the two side parts of the slide in wet filtering paper, so that while the middle of the slide rested upon the metal, the side parts by means of the filtering paper found upon the hard caoutchouc a safe resting plate. I placed two other strips of paper, several times folded, and moist on the slide, so that one lay before and the other behind the line. While from time to time I moistened these strips. My preparation, in spite of the artificial heating, was still sufficiently protected from drying. Before the microscope I erected finally a large shade so that it hid the spirit flame from the observer's eye. By this means, moreover, my retina was protected as well as possible from lateral light. I can therefore, in spite of the loss of light which I suffer on account of the heating table, still always work with strong lenses.

If it be desired to attend to a greater number of preparations at one time, when it is not possible to keep the preparation continuously under the microscope, and yet desirable to follow the processes in certain situations, it is well to mark the preparation with characters. In connection with this, untwisted silk fibres render excellent service.

Two parallel ledges of wax having been melted on to the slide, if two untwisted silk fibres drawn out of the cocoon, if to be had, be stuck upon them at right angles, and then the covering glass provided with the little drop, be laid down in such a way that the silk fibres pass through the preparation, this will easily offer the necessary marks for finding again without difficulty a given place even with the strongest powers. The keeping of notes in which the characteristic one indicated in writing and diagram will then be scarcely dispensable.

(To be continued.)

NARROWING OF THE AIR-PASSAGES BY SYPHILIS.

(From the German, by DR. C. R. DRYSDALE.)

DR. TRENDELENBURG (*Arch. f. Klin. Chir.*) remarks that narrowing of the trachea, not in consequence of compression through strumous or other swellings, but narrowing of its calibre by contraction of scars of the mucous membrane after ulceration, or through thickening of the submucous tissue, is not often met with; as a general rule this is the consequence of syphilitic inflammation. The symptoms of tracheal stenosis are in general the same as in narrowing of the larynx, i.e., gradually increasing dyspnoea. As to therapeutics, the experience of the author teaches that such strictures of the windpipe as are caused by thickening and scars of the mucous membrane, if they are at the level of the thyroid cartilage, can be treated quite like strictures of the urethra, and dilated. If early seen, they may be treated by bougies passed into the trachea through the mouth. In the great majority of cases, the narrowing is first noticed after great dyspnoea has been caused by it, and we must perform tracheotomy. Tracheotomy must then, of course, be made below the level of the thyroid cartilage, and it is advisable to make it as far below as possible in order that, later, the stricture may lie entirely above the air fistula, and still be separated from it by a piece of healthy mucous membrane. We can also be pretty certain that after tracheotomy acute purulent oedema is a most rare occurrence. When tracheotomy is performed beneath the stricture, we wait for some weeks for the treatment of the disease, until the patient, who has been exhausted by long want of breathing, becomes quite recovered. Then there are two methods of treatment which may be adopted—(1) The passage of bougies, and keeping in of two tubes in the stricture without incision; and (2) the external splitting of the stricture. The first method can be tried in not too narrow strictures in all

cases. But we do not go far by passing bougies through the fistula; it is far better to pass them through the mouth and larynx. The author uses as bougies the ordinary English oesophagus bougies, or rectum bougies, conically formed, which are first of all oiled, and are easily bent. The passing in of the bougies into the larynx is usually easy, as also their extraction. Leaving of the bougies for a short time hinders the quickly supervening and profuse salivation. If the stricture cannot be widened in this way, we must split it from without. The author has but little experience of syphilitic necrosis of the larynx. Dyspnoea from affection of the epiglottis comes on where there is oedema, necrosis, and bending back of the organ. Scars in the pharynx so severe as to cause dyspnoea are very rare indeed.

Literature.

A DICTIONARY OF CHEMISTRY AND THE ALLIED BRANCHES OF OTHER SCIENCES (a).

NEARLY four years have elapsed since the fifth and concluding volume of Watts' Dictionary of Chemistry was completed, but in the preface to the last volume the author refers to the changes that had already taken place in our knowledge during the nine years which were required for the writing of this laborious work. As the suggestion for a periodical supplement first appeared in the pages of this journal, we need hardly state that the design of the present undertaking meets with our hearty approval. Indeed, we imagine that the idea must have equally grown with the author during his labours—for the necessity is obvious.

It is impossible to read such a work through—but from the practical and searching test that we have put this 6th, or supplementary volume to, we have no hesitation in saying that it fairly represents the chemistry of the last four years. Some few oversights there are and must be in such a compilation. Extraneous articles are also included by Professor Foster on Electricity, Paul "On the Metallurgy of Iron," and Roscoe "On the Chemical Action of Light," "Spectrum Analysis," &c. Watts' Dictionary is now become so thoroughly an institution in connection with English chemistry that as long as the author is in harness we are sure he will find himself under a moral obligation to write up a supplement; we might be allowed to suggest in less periods than four years. A *propos* of Dr. Paul's article upon the metallurgy of iron, it reminds us of the more technical character of some of the articles in this volume than those of the previous ones. This phase might be pushed still further with advantage. Thus, under the head of "Phenylamine" we have all the recent chemistry done in connection with its derivatives, whilst under the head of "Aniline" we have the most recent improvements in the manufacturing of that body. Continual reference to other works is more suited to the views of publishers than the convenience of the readers, or the utility of the work. All matters connecting chemistry with biology are carefully collated, such, for instance, as C. Bernard's physiological classification of the opium bases.

LECTURE NOTES FOR CHEMICAL STUDENTS (b).

THIS work is to supply the students attending lectures with glyptic formula and graphic notation of the most important compounds; at the same time the author avoids description of the properties of bodies. We have now merely to notice the completion of the new edition of this

(a) "A Dictionary of Chemistry and the Allied Branches of other Sciences." Supplement. By Henry Watts, F.R.S., &c. London: Longmans, Green and Co., 1872.

(b) "Lecture Notes for Chemical Students." By Edward Frankland, F.R.S., &c. Vol II. "Organic Chemistry." Second edition. London: J. Van Nostrand, 1872.

book, viz., the organic part. The author's definition of organic chemistry is ingenious, although it is perhaps doubtful if it would bear a thorough investigation. Thus, carbonic anhydride is mineral or inorganic according to Professor Frankland's definition, because the oxygen is not directly combined either with carbon, nitrogen, or hydrogen, but is combined with oxygen. It is curious to observe that Laurent, who also made carbon his divisional element, and said organic chemistry was the chemistry of carbon, classified this very carbonic anhydride as an organic substance. It is hardly fair, however, for the writer of this review to criticise this definition, as he is peculiar in his views, and holds that there should be no division of chemistry into inorganic and organic—which is unphilosophical. Also that if such a division is made, it would be better to adhere to the simple definition, that organic chemistry deals with those compounds produced by animal or vegetable life, and the derivatives of such compounds. In this second volume we have a systematic attempt to convey the principles of molecular arrangement, or constitutional formula, and, although in some cases the range of demonstrated phenomena is overstepped, it is self-evident that the chemists of 1872 have advanced too far to be satisfied with anything less than constitutional formulæ.

"POPULATION, OR THE LAW OF INCREASE" (a).

WE have been favoured with some pamphlets by an American *confrère*, which are very curious as evincing the great interest taken in population by our brethren in the United States. In his last pamphlet entitled "Lessons on Population suggested by Grecian and Roman History," our author quotes Professor Seely, who asserts that, whatever the remote and ultimate cause may have been, the immediate cause to which the fall of the Roman Empire may be traced is a physical, not a moral, decay. While the aversion to marriage and the unwillingness to multiply are mentioned as becoming stronger and stronger, the historian nowhere undertakes to explain the cause of such perversity of disposition. Professor Seely adds—"The same phenomenon had showed itself in Greece before its conquest by the Romans. There the population had even greatly declined; and the shrewd observer Polybius explains that it was not owing to war and plague, but merely to a general repugnance to marriage and reluctance to rear large families, caused by an extravagantly high standard of comfort." "For when," says Polybius, "men gave themselves up to ease and comfort and indolence, and would neither marry nor rear children born out of wedlock, or, at least, only one or two in order to leave these rich and to bring them up in luxury, the evil soon spread imperceptibly, but with rapid growth; for when there was only a child or two in a family for war or disease to carry off, the inevitable consequence was that houses were left desolate and cities by degrees became like deserted hives. And there is no need to consult the gods about the modes of deliverance from the evil, for any man would tell us that the first thing we have to do is to change our habits, or, at all events, to enact laws compelling parents to rear their children."

Dr. Nathan Allen remarks that—"Some comparison may be made between the population of the United States of the present time with ancient Greece and Rome. He states that, whereas among the first settlers there was an average of about eight children to a family, it is doubtful whether the average number of children to each family now exceeds three. It is estimated that the number of families having no children or only one composes now about one-third of all New England families. Closely connected

with this topic is another ominous feature of the times, that the marriage rate is relatively decreasing."

"Again," says Dr. Allen, "connected with and growing out of this selfish view of marriage, the sacredness and permanence of the institution sit lightly upon such parties. Causes for divorce are easily found. If divorces continue to multiply, as they have done for a few years past, this will certainly tend to weaken the relation and make it more and more unstable." After speaking of arts of prevention and destruction, of which he says it is difficult to decide which is the most pernicious, he adds, "one thing is certain, they are all in motive, in inception, and in execution, criminal in the sight of the Creator." To this eloquent appeal to *ad verecundiam* we might reply in the words of one of the Roman authors—"Divis injuriæ, Diis curæ."

Within the last half-century there has grown up in Massachusetts a foreign element by birth and parentage, equal to almost one-third of its whole population. This foreign element is increasing far more rapidly than the native class, having, relatively, nearly one-third more births yearly than the strictly American people. It is now two hundred and fifty years since the first settlement of New England, and "as a people," says Dr. Allen, "we are already reaching a crisis—a culminating point in history—where it is becoming a question whether there is from year to year any actual increase or not of native population."

Correspondence.

MALTHUS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your journal of the 3rd inst. I observe a notice of the well-known work of "Malthus on Population." This notice is by Dr. Drysdale, of London. With the object of the work or its general principles I have nothing here to do. But it has often struck me as strange that so little exception, even by the Profession, has been taken to the pervading idea which runs through the whole work, viz., that the increase of the population is only limited by the supply of food. In other words, if the supply of food be without limit the population will increase in the same ratio. Now, this view of the question is erroneous, and though it has been objected to and even written against, it still seems to hold possession of the public mind. As physiologists, however, I think we are called on to set the matter right. But I cannot at present do more than draw attention to the question.

I am, Sir, yours,

HENRY KENNEDY.

Dublin.

CONTAGIOUS DISEASES ACTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am glad to see that some able Liverpool physicians have at last spoken out against the Acts which are such favourites with some of your contemporaries. Much as I should desire to agree with yourself and with the editors of the *Lancet* and *British Medical Journal* in all points, (if that were possible), I cannot help saying that, whatever there may be to be said in favour of the Contagious Diseases Acts, there are so many points against such partial Acts, that I am sure no one can expect that a free people like the British, or the Americans of the United States will be likely to accept them without due evidence in their favour. Now this is precisely what is wanting. Your able contemporaries are so convinced of the value of the Acts, that they cannot bear that anyone should be heard on the negative side. A mode of treating a subject which is often successful enough in countries where liberty of the press does not exist, but which does not now succeed so well as formerly in England, because dissenters from the dominant opinion, often get up a paper of their own. This is what has been done by the opponents of the Acts, in publishing their weekly organ, the *Shield*.

(a) "Population, or the Law of Increase." "Intermarriage of Relations." "Physical Deeneracy." "The Physiological Laws of Human Increase." "Lessons in Population suggested by Grecian and Roman History." By Nathan Allen, M.D., of Massachusetts, U.S.

You are good enough to say, that although you do not always agree with me in questions of public hygiene, yet that I am *suaviter in modo*, if perhaps rather *fortiter in re*, and thus do not offend more than is necessary when stating my opinions. Will you then allow me to say that it seems to me that the extension of the Contagious Diseases Acts to the whole population of this country, would in my idea be a most retrograde step. At present we are hoping that woman may become less helpless and better educated, and therefore less liable to being deceived by those who are supposed to "protect" them, but these Acts certainly tend in the opposite direction. They are most partial, and let men off without any fine or punishment, for Acts which entail both on women. It would, I affirm, be much better to have an army of domestic soldiers, than to lose so many of our men's services by syphilis as we now do. Similar Acts on the Continent do not succeed in very much lessening syphilis. Why then should we be asked to accept such legislation in a hurry and without argument? Please to prove your case, Sir, and let your brother editors do the same, hearing all our remarks on the other side, and then, but not till then, shall we leave off opposing these Acts.

I remain, yours, &c.,

CHARLES R. DRYSDALE, M.D., M.R.C.P.L., F.R.C.S.E.

Medical News.

University of London.—The following are lists of the candidates who have passed the Preliminary Scientific (M.B.) Examination:—

FIRST DIVISION.

Barnard, John Henry, private study
 Blake, William Henry, University College
 Blamey, James, University College
 Briggs, Harry Beecham, King's College
 Carrington, Robert Edmund, Guy's Hospital
 Chremont, Claude Clarke, University College
 Evans, Charles Walter, University College
 Fox, Richard Hingston, London Hospital
 George, George Aldridge, University College
 Goodchild, Francis, Epson and University Colleges
 Bellier, John Benjamin, Leeds School of Medicine
 Henderson, George Courtenay, University College
 Hooswood, William Francis, Manchester Grammar School
 Le Queue, Edwin Joseph, St. Bartholomew's Hospital
 Lowe, Howard Griffiths, Queen's College, Birmingham
 Marshall, A. Mines, B.A., St. John's College, Cambridge
 Mercer, Charles Arthur, London Hospital
 Neale, John Edward, University College
 Stewart, Howard Douglas, King's College
 Trard, Nestor Isidore Charles, King's College
 Whitelegge, Benjamin Arthur, University College
 Wilton, James Cecil, private study
 Worthington, William Barton, Owen's College

SECOND DIVISION.

Anderson, Richard John, Belfast College
 Baker, Albert de Winter, Guy's Hospital
 Batebury, Richard Legg, King's College
 Blake, Henry, St. George's Hospital
 Bury, Judson Sykes, Owens College
 Duke, Herbert, Guy's Hospital
 Ferrier, John Christian, Guy's Hospital
 Finch, Alfred, Guy's Hospital
 Giles, George Michael James, St. Mary's Hospital
 Gray, Alexander, Guy's Hospital
 Hancock, John Gatehall, King's College
 Hunt, Joseph William, University College
 James, Alfred, University College
 Jude, Richard Henry, Christ's College, Cambridge
 Kidd, Walter Aubrey, Guy's Hospital
 Mabery, William Henry, Edinburgh University
 Miller, Frederic Daniell, King's College
 Pinnel, Thomas Mark, University College
 Powell, Joshua, University College
 Roughton, James Woolley, King's College
 Seward, William Joseph, University College
 Simmonds, William Allason, Guy's Hospital
 Snell, Edward Arthur, King's College
 Vane, Arthur Bayly, Queen's College, Birmingham
 Wilding, Sidney Pateshall, University College

Royal College of Surgeons of England.—The following gentlemen, having passed the required examinations for the diploma, were duly admitted Members of the College at meetings of the Court of Examiners on Monday, Tuesday, Wednesday, Thursday, and Friday last:—

Adams, John, Kingsbridge
 Applesand, John, Burnley
 Armstrong, Robert Stow, Bedford
 Armstrong, Thomas Britten, Leeds
 Athness, Walter Mark, L.S.A., Chesnut, Hereford

Baker, Charles E., Shrewsbury
 Balkwill, William Edward, L.S.A., Kingsbridge, Devon
 Barber, Oliver, L.S.A., Sheffield
 Barfoot, George Harry, Leicester
 Bartlett, Edward, Cunnaght Square
 Bradnell, George David, L.R.C.P. Edin., Newton Abbott
 Bell, George Pearson, Leicester
 Bellingham, Joseph, Dudley
 Blackburn, Charles W. A., Mauritius
 Blackburn, Herbert Belayse, Petworth
 Blackbaw, Thomas Wilkinson, Stockport, Cheshire
 Boeson, George, L.S.A., Barnstaple, Devon
 Bracey, Herbert Richard, L.S.A., Birmingham
 Brewer, Reginald E. W., Newport, Monmouthshire
 Brown, James, Edinburgh
 Brown, William, Carlisle
 Burgess, Edward Arthur, L.S.A., Bethnal-green Road
 Carolan, James Frederick, Maida Hill
 Colgate, Henry, Eastbourne
 Cole, William James, Harrow Road
 Collinson, Alfred Cockburn, Egin Road
 Cripps, William Harrison, Mitre Court, Temple
 Davies, George Augustus, L.S.A., Newport, Monmouthshire
 Davies, John Hopkin, L.S.A., Lampeter, South Wales
 Dodd, Thomas Anthony, Newcastle-on-Tyne
 Dorin, Arthur F. L., L.S.A., The Grove, Brompton
 Duncan, Andrew, L.S.A., Henrietta Street
 Dunn, William Allison, L.S.A., Louth, Lincoln
 Eastes, Thomas, L.S.A., Folkestone
 Edge, Abraham Matthewson, Manchester
 Elam, Shroffeld, L.S.A., Woburn Square
 Eskell, Maurice Moses, Grosvenor Street
 Fagg, Thomas H., L.R.C.P. Lond., Bayswater
 Finzi, Judah Moses, Gower Street
 Gheny, George Wallis, Barking, Essex
 Godlee, Rickman I., Walthamstow
 Godding, Charles Lane, Fostonmouth
 Greenfield, William Smith, Haverstock Hill
 Grant, Garden Milne, Dover
 Greaves, Frank, L.S.A., Eastleigh, Hants
 Griffiths, Alfred Vavasour Stone, Staffordshire
 Griffiths, William E., L.S.A., Kensington
 Hall, James Thomas, Ashbourne
 Hansall, William Charles, Caen, France
 Harrison, Henry Baskcomb, St. Lawrence Road, Notting Hill
 Hartridge, Gustavus, L.S.A., Shrewsbury
 Hawkins, Henry Baillie, Topcliffe
 Heald, George Henry, Leeds
 Hey, Edward, Leeds
 Hex, Henry, Plymouth
 Hughes, Robert Harry, Putney
 Hulder, William, L.S.A., Hull
 Imlach, Francis, M.B. Edin., Liverpool
 Irving, William George, Long Bennington, Lincolnshire
 Kebbell, Alfred, Hackney
 Lawrence, James, M.D., Queen's University, Ireland
 Lawton, Herbert A., L.R.C.P. Lond., York Road
 Lucas, Thomas D'Acy, M.D. McGill Coll., Stratford, Canada
 Lungley, Frank, L.S.A., Lewis
 Madden, Edward Monson, M.B. Edin., St. John's Wool
 Massingham, John Payne, Warrington
 Mawson, William Arthur, Boston Spa, Lincolnshire
 Measures, John William, Spalding, Lincolnshire
 M'Conkey, Thomas Clarkson, M.D. McGill Coll., Ontario
 Monro, Charles Edward, Hurstperpoint
 Morgan, John Hammond, Sussex Place
 Morgan, William Lewis, L.R.C.P. Lond., Merthyr Tydfil
 Morley, John Lacy, Leamington
 Murray, Thomas, Indian Army
 Murrell, Clement F. F., L.S.A., Great Yarmouth
 Mutch, Robert Samuel, Prince Edward's Island, Canada
 Nankivell, Charles A., Torquay
 Norther, Gilbert William, Tavistock
 O'Reilly, Walter William Joseph, Queen's University, Ireland
 Otley, Walter, Twickenham
 Owen, Albert L., Holloway
 Paramore, Richard, L.S.A., Hunter Street
 Parry, Thomas Sharp, Mold, Flintshire
 Peacey, William, Bermondsey
 Phillpott, Joseph Henry, Croydon
 Poignaud, Malcolm, Jersey
 Porter, Joseph Francis, Dublin
 Reid, Frank, L.R.C.P. Edin., Torrington Square
 Richards, John Edward, L.R.C.P. Lond., Ruabon, N. Wales
 Riedman, George Owen, Dolton, North Devon
 Robinson, Mark, Portsmouth
 Robinson, John Edward, Rotherham
 Rogers-Harrison, Napoleon A., L.R.C.P. Lond., Lansdowne Bldg.
 Sayer, Charles Watlen, L.S.A., Yatton, Somerset
 Scott, John Walter, L.S.A., Torpoint, Cornwall
 Scithorpe, Alfred Milward, L.R.C.P. Edin., Tamworth
 Smith, George Cockburn, L.R.C.P. Edin., Winchester
 Smith, Henry Hammond, Devonshire Place
 Smith, George F. K., L.S.A., Northampton
 Smilhart, Charles Lawson, Manchester
 Snell, John, Leeds
 Sobey, Arthur Lyne, Saltash, Cornwall
 Spencer, Lawrence Wilson, Preston
 Stirling, Edward Charles, Queen's Gardens
 Stocker, Charles Joseph, Stratford
 Strother, William H. H., L.R.C.P. & L.M. Edin., Darlington
 Taylor, Seymour, Burton-on-Trent
 Toone-Smith, Thomas W., M.D., Austrey, Warwick
 Turner, George, L.R.C.P. Lond., Portsea, Hants
 Utting, James, L.S.A.
 Verley, Reginald Louis, L.R.C.P. Edin., Gower Street
 Walker, William Newman, L.S.A., Tooting Park

Wallace, William, Kingalund
 Ward, Joseph, Warwick
 Warne, William Colston, M.B. Edin., Rochester
 Welchman, Edward, L.R.C.P. Lond., Winchester
 Welsh, William K. B., Cornwall Road
 White, George Bentley, Nottingham
 Willmott, Julius John Eardley, Fenge, Surrey
 Withers, Robert, Stoke, Devonport
 Williams, William, Fishguard
 Williams, Howell, Great Hamston, near Cardiff
 Woodhouse, Robert Hall, Anstey, Dorsetshire

The following gentlemen passed the primary examination in Anatomy and Physiology on the 18th inst. :—

J. H. Gilmour, J. Crossman, F. T. Jones, and A. Turle, St. Thomas's Hospital; E. A. White, F. H. Elliott, and J. H. Badcock, University College; H. M. Barker, H. H. Bathe, and A. K. Bisall, St. Bartholomew's Hospital; C. S. Canbie, Dublin; A. Carter, E. S. Newton, and J. H. Paley, Guy's Hospital; A. F. Hawkins, Leeds; H. H. Hughes, King's College; Thomas D'Arcy Lucas, Canada; H. E. Paxton, London Hospital; J. M. Raye and G. P. Stockwell, St. Mary's Hospital.

Death of Dr. Aldis.—On Friday last, this eminent member of our Profession passed away as suddenly as the fact is melancholy to chronicle. He had attended the Council of the Royal College of Physicians of London on Thursday evening. On Friday morning he went to his Hospital, and on his return partook of luncheon, and dozed in his arm chair as usual. From this he never awoke. Dr. Aldis's life was one of too great usefulness not to need a longer notice than this at our hands, and we propose to revert to it in our next.

Apothecaries' Hall of London.—At a Court of Examiners held on the 25th instant the following gentlemen, having passed the necessary examinations, received the L.S.A. diploma, viz. :—Messrs. Gerald Bomford, of Vernon Place, Bloomsbury; Frederick Canton, of Great Marlborough Street; A. F. Loch Dorin, of Thistle Grove, Brompton; Alfred William Emms, of Ilminster; Matthias Groves, of Radpole, Weymouth; Henry Baskcomb Harrison, of St. Lawrence Road, Notting Hill; John O'Connell Hynes, of Nottingham; and William Wallis, of Hartfield; and at the same court Messrs. John Rendall, of Guy's Hospital, and Herbert Henry Thomas, of University College, passed the primary professional examination.

Parliamentary Intelligence.

HOUSE OF COMMONS.

THE PUBLIC HEALTH BILL.

THE House having resolved itself into Committee on this Bill, Clauses 1 and 2 were passed without discussion.

On Clause 3, which divides the country into urban and rural sanitary districts, Mr. GOLDNEY said that the proper and successful carrying out of the provision of the Bill would depend much upon the selection of a suitable body in whom to vest the powers. Boards of Guardians had failed to discharge the duties imposed upon them by previous statutes, and he believed that a County Board would perform the duties created by the present Bill in a more effective manner. Its accounts would be regularly published, and its proceedings would receive greater publicity and be more widely criticised than those of the guardians, the only effectual check to whom would be the Local Government Board. The County Boards he proposed would be formed of county magistrates elected at quarter sessions, with an equal number of representatives elected by Boards of Guardians.

Mr. CORRANCE concurred in the amendment, as also did Mr. DALRYMPLE; and in reply to a remark made on a former occasion as to the power the Bill would place in the hands of the Medical Profession, the latter gentleman said that without the aid of that Profession sanitary reform would be nowhere. There were some hierarchies that were probably worse than a hierarchy of doctors.

Sir M. BEACH thought the Bill eminently unsatisfactory in the choice of local authorities, and was opposed both to Town Councils and Boards of Guardians.

Sir C. B. ADDERLEY, on the other hand, was strongly in favour of Boards of Guardians, which, among other advantages, existed already, and could be set to work at once.

Mr. STANSFELD, in defending the Union as the unit of administration, denied that the Guardians had failed to do their

duty, and stated that he had ascertained that the majority of them were prepared to undertake these sanitary functions.

Mr. HURST objected to Boards of Guardians which had been tried and found wanting. He preferred a County organisation.

Mr. GOLDNEY having withdrawn his amendment, the opinion of the Committee was taken on an amendment moved by Mr. CORRANCE to Clause 5, which raised the point in a more direct form. On a division, the Committee decided in favour of Boards of Guardians by 84 to 7.

The House remained in Committee until long past two o'clock, and succeeded in disposing of all the clauses up to Clause 41.

Gleanings.

Spasmodic Muscular Contraction—Arterial Compression.

M. BROCA had under his care, a few months ago in the Hôpital de la Pitié, a man who had broken both bones of his legs an hour before his admission to the hospital. The muscular contraction was so violent that it was impossible to reduce the fracture. M. Broca thereon employed a method which he had found successful in cases of painful cramp of the lower limbs viz., compression of the femoral artery. Almost immediately the muscles became relaxed, and reduction was effected with ease. Subsequently in re-applying the splints, the contraction returned, and was overcome by the same means.—*Medical Record.*

Spina Bifida Cured by repeated Tapping and Pressure.

At the meeting of the Lisbon Society of Medical Sciences on February 17th, Dr. Camara Cabral communicated a case of congenital spina bifida which he had successfully treated. The patient was a child aged twenty-five days, which was brought into the St. Joseph Hospital on November 21st. It had in the lumbo-sacral region a swelling forty centimeters in circumference, seventeen in vertical, and ten in transverse diameter, and six in depth. It fluctuated, was transparent like a hydrocele, and appeared to contain not only fluid but some solid body. Pressure on it did not produce any convulsions, nor were there any paralysis or other symptoms denoting lesion of the spinal cord. It was therefore concluded that the tumour consisted exclusively of a hernia of the meninges, filled with fluid. On the 29th it was tapped with a Dieulafoy's trocar, and 400 grammes of a transparent yellow fluid, containing an abundance of albumen, were removed. Compression was applied by means of adhesive plaster. No symptoms followed the operation, beyond some vomiting and loss of appetite. Some days later, the tumour having again enlarged, 250 grammes of liquid were removed; and on December-14th, 425 grammes. The defect, which was found to be in the situation of the fourth and fifth lumbar vertebrae, was gradually diminishing. On a fourth and a fifth occasion, puncture was performed at intervals of some days; the quantities evacuated being respectively 175 and 125 grammes, and the fluid being more highly albuminous than before. After the last two operations, there was some meningitis, which yielded to ordinary remedies. The child made a good recovery, and was exhibited at the meeting at which the case was described.

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this request.

All communications intended for insertion, must bear the name and address of the writer; not necessarily for publication, but as a voucher of good faith.

Rejected MS. will always be returned, if a request be received from the author, within one week after the article or letter has been declined.

SUBSCRIPTIONS IN THE UNITED STATES.—A Correspondent has drawn our attention to the fact, that some of the houses in the United States are charging the enormous figure of 15 dollars per annum (more than £3) for supplying this Journal to different parts of the States. We beg, therefore, to state that we shall be happy to supply the same regularly post free per annum, if paid in advance, for considerably less than half this amount, viz., six and-a-half dollars (about £1 6s. 6d.), either direct from our offices in this country, or through our recognised agents in the United States.

To our SUBSCRIBERS.—It having been suggested to us that it would be a matter of great convenience to Subscribers visiting the metropolis to know where they can give instructions for their letters to be addressed previous to leaving home, we have pleasure in informing them that the Publisher has consented to take charge of letters addressed to his care, and that he will place a desk at the disposal of Subscribers whose names are upon our lists, for short correspondence, where such accommodation is desired.

Dr. BOLTON.—Thanks for your complimentary note. The proposition is perfectly satisfactory.

PSYCHOLOGIST.—1. The meeting of the Medico-Psychological Association takes place to-day (Wednesday), under the presidency of Sir James Coxe, M.D. The date given by our contemporary, the *Lancet*, is obviously a clerical error. 2. Write to Dr. Take, the honorary secretary.

THE STUDENTS' COLUMN.—Dr. Handzel Griffiths's article, "Synoptical Review of the Official Preparations of the British Pharmacopoeia"—(continuation)—will appear in our next.

Dr. G. E.—We can hardly understand that our contemporary should be guilty of such discreditable proceedings, and hope you are labouring under a mistake.

INFLUENCE OF MEDICAL MEN OUTSIDE THE PROFESSION.—At the annual meeting of the Scottish Midland and Western Medical Association on Friday last, Dr. Boyd, of Slamannan, in the chair, Dr. Moffat, of Falkirk, read his report as secretary, and Dr. Goff, Bothwell, read the treasurer's report, which were both adopted. The report stated that the association had used its influence with some success in respect of the Master and Servants Wages Bill, in communicating with different members of Parliament. The meeting resolved that a communication be made with both masters and workmen in collieries and other works, with the view of getting the monthly medical off-take raised from 6d. to 1s. per month, and expressed confidence regarding the reply from both employers and employed.

A CASE OF REAL DISTRESS.
 "Perhaps you will hardly believe it when I tell you that for the last eleven weeks a piece of meat of any kind has not been upon my table. Please destroy this letter when you have read it, as I would sooner starve than that the world should know it." The above melancholy picture is drawn from the letter of a Professional brother, now full of years, and in deep distress. The writer is an author of no mean pretensions, and the contributor of several clever papers to this Journal in times past. He is a M.D. of a British University by examination, and to our personal knowledge is in every sense of the word, fully deserving the sympathy of the Profession. The cause of his distress is an old told story. He became security for a friend, that friend (sic) bolted, and the poor fellow was sold out of house and home, and the few hundreds he had saved, as some provision for old age, went with his furniture to satisfy the demands of the holders of his guarantee, and save himself the disgrace of imprisonment. The victim of these cruel circumstances has no idea that any appeal is being made on his behalf; and it is only by a mere accident that we have become acquainted with the real facts of the case. Upon reading this, should anyone feel disposed to join in aiding him; any contributions—however small, even a sixpence, or a shillings-worth of postage stamps—will be thankfully received and acknowledged in our next number if sent to Mr. A. Tindall, at the London office of this paper, 20 King William Street, Strand. In deference to the feeling of the gentleman concerned we have refrained from mentioning any name, but our readers may feel perfectly certain that the foregoing and story is but too true.

OPERATION DAYS AT THE LONDON HOSPITALS.

WEDNESDAY, July 31.

- MIDDLESEX HOSPITAL.—Operations, 1 P.M.
- ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations 1½ P.M.
- St. BARTHOLOMEW'S HOSPITAL.—Operations 1½ P.M.
- St. THOMAS'S HOSPITAL.—Operations, 2 P.M.
- St. MARY'S HOSPITAL.—Operations, 1½ P.M.
- KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.
- GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.
- UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.
- St. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.
- LONDON HOSPITAL.—Operations, 2 P.M.
- CANCER HOSPITAL.—Operations, 3 P.M.

THURSDAY, August 1.

- St. GEORGE'S HOSPITAL.—Operations, 1 P.M.
- ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M.
- UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.
- ROYAL ORTHOPEDIC HOSPITAL.—Operations, 2 P.M.

VACANCIES.

- Board of Police, Glasgow. Sanitary Medical Officer, at a salary of £60 per annum. (See advt.)
- Fever Hospital Dublin. Two Resident Pupils. (See advt.)
- Royal Hospital for Diseases of the Chest, London. Physician. Honorary. (See advt.)
- Warneford Lunatic Asylum. Medical Superintendent. Salary £260, with board and residence.
- Westminster Hospital. House-Surgeon. Board and residence, without salary.
- Shoreditch, East London, Parish of St. Leonard. Dispenser. Salary £120.
- London. Lambeth Parish. Medical Officer. Salary £100, with board and residence.
- Liverpool Royal Infirmary. Lectureship on Comparative Anatomy and Zoology. Also the Demonstratorship of Physiology in the Medical School.
- Newtown and Llanidloes Union. Medical Officer. Salary £80.
- Halifax Infirmary. Assistant House-Surgeon. Salary £40, with board.
- Ballyshannon Union, Ballintra District. Medical Officer. Salary £70 per annum, exclusive of fees. (See advt.)

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

- A Treatise on the Causes of Heart Disease. By F. W. Moinet, M.D. Edinburgh: Bell and Bradfute.
- Cooley's Cyclopædia of Practical Receipts. Edited by Prof. Tuson. London: J. and A. Churchill.
- The Beginning of Life. In 2 vols. By H. Charlton Bastian, M.D., F.R.S. London: Macmillan and Co.
- The Case of Clarkson v. Blair in Melbourne.
- La France Médicale; The Monthly Review of Dental Surgery; Boston Medical Journal; Canada Medical Journal; Allgemeine Wiener Medizinische Zeitung; Le Mouvement Medical; Pharmaceutical Journal, &c., &c.

APPOINTMENTS.

- CATON, R., M.D., Lecturer on Physiology at the Liverpool Royal Infirmary School of Medicine.
- COUGHNEY, M., M.B., Demonstrator of Anatomy at the Liverpool Royal Infirmary School of Medicine.
- GUNNING, J. St. C., L.R.C.S.I., Resident Medical Officer to the Ramsgate and St. Lawrence Royal Dispensary and Seamen's Infirmary.
- HACKNEY, A. H., M.R.C.S.E., Medical Officer for the St. Mary District of the Parish of St. Marylebone, London.
- HIGARTY, J., M.D., Medical Officer, &c., for the Cloonbar No. 1 Dispensary District of the Oughterard Union, co. Galway.
- KENNY, J., L.R.C.S.I., Medical Officer and Public Vaccinator for the Whitwell District of the Workop Union, Notts.
- LLOYD, R. E., M.B., Resident Medical Officer to the Fever Hospital and House of Recovery, Cork Street, Dublin.
- MILLER, J., M.D., Surgeon to the G Division of the Metropolitan Police.
- MILLER, J. A., M.R.C.S.E., Surgeon to the G Division of the Metropolitan Police.
- ROSS, D. M'C., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer to the Workhouse, Monaghan Union.
- SANSOME, T., M.R.C.S.E., Honorary Surgeon to the West Bromwich District Hospital.
- SUTCLIFFE, H., M.R.C.S.E., Honorary Surgeon to the West Bromwich District Hospital.
- WATERS, A. T. H., M.D., Lecturer on the Principles and Practice of Medicine at the Liverpool Royal Infirmary School of Medicine.

Marriages.

- HELDON—NICHOLS.—On the 18th inst., at Southrepps, Fred. A. Haldon, M.R.C.S.E., of North Walsham, to Elizabeth Cross, only daughter of John Nichols, Esq., of Southrepps Hall, Norfolk.
- MORRIS—COX.—On the 18th inst., at the Abbey Church, Dorchester—Thomas, Malcolm Alexander Morris, M.R.C.S., to Fanny, elder daughter of Thomas Cox, Esq., of Dorchester.
- SMITH—SMITH.—On the 18th inst., at the Parish Church, Marske, Jas. Broom Smith, Esq., of Loftus in Cleveland, to Maud, youngest daughter of the late Rev. William Henry Smith, M.A., Rector of Hinderwell, Whitby, Yorks.
- THOMPSON—WATKINS.—On the 25th inst., at Potter's Bar, Edmund Symes Thompson, M.D., Physician to the Hospital for Consumption, Brompton, to Elizabeth, younger daughter of the Rev. H. G. Watkins, M.A., Vicar of St. John's, Potter's Bar, Middlesex.
- WILLIS—WHITE.—On the 18th inst., at All Saints', Sheffield, Julian Willis, L.R.C.P.E., &c., of Sutton-Scotley, near Michaldever Station, Hants, to Fanny Alicia, eldest daughter of Robert White, Esq., of Woodhill, Grimsthorpe.

Deaths.

- CALDER.—On the 25th of June, Gillies Calder, M.R.C.S.E., of Warbleton, Sussex, aged 57.
- CUMMING.—On the 16th of July, W. S. Cumming, M.R.C.S.E., of Limehouse, aged 78.
- EGAN.—On the 28th of June, Edward Egan, M.R.C.S.E., of Aungier Street, Dublin, aged 52.
- JONES.—On the 12th of July, R. Jones, M.D., of Newtown, Montgomeryshire, aged 57.
- LACEY.—On the 23rd of July, John Lacey, L.S.A.L., of the Wyle Cop, Shrewsbury.
- LAMBART.—At Steamer Point, Aden, R. B. Lambert, L.R.C.S.I., Staff Asst.-Surgeon Army.

BALLYSHANNON UNION.

BALLINTRA DISPENSARY DISTRICT.—The Committee of the above Dispensary District will, at their Meeting, to be held in BALLINTRA, on TUESDAY, 6th August, at One o'clock p.m., proceed to appoint a MEDICAL OFFICER for the District, at a Salary of £70 per annum, exclusive of Vaccination Fees. Applications with Testimonials, &c., to be sent to JOHN ATKINSON, Esq., J. F., Cavangarden, Ballyshannon. Personal attendance of Candidates required. The Medical Officer appointed will have to reside in Ballintra. July 25th, 1872 J. B. CHISM, Clerk of Union.

LEDWICH SCHOOL OF SURGERY.

SUMMER SESSION, 1872.

At the termination of the above Session the following GENTLEMEN were awarded PRIZES for Superior Answering in the subjoined Subjects—

Materia Medica—J. H. COURTENAY (1st); W. KEAYS (2nd); and R. BAXTER, Certificate.
Chemistry—W. KEAYS (1st); T. LEONARD (2d).
Forensic Medicine—W. KEAYS.
Botany—M. TAAPPE (1st); P. GORMAN (2nd).

KDW. LEDWICH, Secretary.

The School will re-open for DISSECTION on the First of October. July 16th, 1872.

TO PHYSICIANS.—The friends of a Lady, whose mind is occasionally affected, desire to place her in a Physician's family where she would be treated with care and kindness, and have a happy home. Please state terms in reply. References given and required. —P. D., Office of MEDICAL PRESS, Molesworth Street, Dublin.

NAVAL MEDICAL DEPARTMENT, ADMIRALTY,

Somerset House, W.C., 6th July, 1872.

NOTICE of EXAMINATION for ENTRY of ASSISTANT-SURGEONS in the ROYAL NAVY.—Notice is Hereby Given that a Competitive Examination for the admission of Assistant-Surgeons into the Royal Navy will take place at the University of London, Burlington-gardens, on MONDAY, 12th August, 1872, and following days, at 10 o'clock.

Candidates must present themselves at this Department on THURSDAY, 8th August, 1872, bringing with them the various certificates of qualifications specified in the Regulations of the 24th June, 1871, when, should they be found in all respects eligible, they will be permitted to appear for examination. A. ARMSTRONG, Director-General.

BOARD OF POLICE OF GLASGOW.

SANITARY MEDICAL OFFICER WANTED.—The Board of Police of GLASGOW hereby invite Applications for the Office of MEDICAL OFFICER for the City, to perform the duties of said Office as specified in "The Glasgow Police Act, 1866," and the "Public Health (Scotland) Act, 1867," and such other Sanitary Medical Work as may from time to time be required by the Board or its Health Committee. The gentleman to be appointed to devote his whole time to the duties of the office. Salary £630 per annum.

Applications to be lodged in the hands of the Subscriber on or before 2nd August, proximo, marked "Application—Medical Officer." JOHN LANG, Clerk to the Board. Central Police Chambers, Glasgow, 7th June, 1872.

MAUGHAM'S

COMPOUND SOLUTION OF IRON.

The tonic influence of Iron on the living tissues, its promoting digestion by stimulating the digestive organs to extract more nutritive matter from our food, and causing a larger quantity to become more adapted for assimilation, has long rendered it a valuable agent in the hands of the Medical Practitioner.

Some of the preparations of Iron in use are objectionable, either on account of being nauseous or from being in an inconvenient and uncertain form for administering to patients. This SOLUTION OF IRON will be found devoid of the objections alluded to, it being even so palatable as to cause children to become partial to it.

It is scarcely necessary to remind Medical Practitioners of the efficacy of Iron when administered in cases of relaxation of substance in the living tissues, or in weakness arising from a deficient supply of nervous energy. This Solution of Iron is therefore offered in a fit state for administering either simply with water and syrup, or with quinine, or any other desirable medicine, if in certain cases such adjuncts be deemed requisite.

Prepared only by the Proprietor at the Chemical Works, Park road, Clapham; and sold in stoppered bottles, half-pints 2s. 9d., pin 5s. 6d., and quarts 8s. by all Wholesale Chemists.

N.B.—See Medical Certificates.

QUININE WINE,

AS SUPPLIED TO THE SICK AND WOUNDED DURING THE LATE WAR.

THE many and expensive forms in which this well known medicine is administered too often preclude its adoption as a general tonic. The success which has attended WATERS'S QUININE WINE arises from its careful preparation by the manufacturer. Each wine-glassful contains sufficient Quinine to make it an excellent restorative to the weak. It behoves the public to see that they have Waters's Quinine Wine, for the result of Chancery proceedings, a short time since, elicited the fact that at least one unprincipled imitator did not use Quinine in the manufacture of his wine. All grocers sell Waters's Quinine Wine at 30s. per dozen.

WATERS & WILLIAMS, Original Makers, Worcester House, 34 Eastcheap, London. Agents—Lewis & Co., Worcester.

Established 1848.

PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S.,

&c. (KING'S COLL.), and Author of VIA MEDICA,

Has always upon his books a large number of desirable investments and available Appointments for negotiation.

The business of the Professional Agency is based upon the general principle that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

PRACTICES AND PARTNERSHIPS NOW OPEN for Negotiation (in addition to those advertised in Dr. Langley's List (which is sent post free on application).

Y 512. First-class COUNTRY PRACTICE, in a pleasing part of the Home Counties. The connection is very old-established, and is wholly transferable to a suitable gentleman; average receipts upwards of £500 a-year. The residence is pleasantly situated in its own grounds of about an acre. One horse does all the work. No assistant required. All expenses small. Railway station in the village, with easy access to the neighbouring town or to London. No Union appointment or low class Midwifery. The district is improving, and the practice increasing.

Y 511. Non-dispensing PRACTICE, in a charming locality, within a few miles of LONDON. The Vendor having private means, has not pushed the Practice, which could be largely increased. The receipts have averaged £350 a-year, but the patients are only of the best class. Visits charged three for £1 ls.; Midwifery has been declined. The present residence is large, convenient, and well situated, with ample facilities for the reception of resident patients. Highest references can be given. The opening would prove highly advantageous to a gentleman with first-class diplomas, accustomed to good society.

Y 519. VALUABLE PARTNERSHIP, in one of the best districts of LONDON, private Practice, exclusive of appointments, upwards of £2,000 a year. Patients of the best class. Midwifery fees, £5 5s. and upwards. Visits, three for £1 ls. No dispensing. A suitable partner could largely increase the practice. One-third share is offered on the basis of two years' purchase. The Diplomas of the College and Hall would be all that are necessary; but a graduate of the London University would be preferred. No gentleman need communicate unless he has at command £1,000.

Y 520. RESIDENCE of a deceased Surgeon TO LET. The House is situate in a pleasant part of the S. W. district, and can be let for £75 a year, or the lease can be sold for £665 subject to a ground rent of £10 a year, part of the purchase money may be left on mortgage.

Y 518. OPEN SURGERY in a pleasant Suburb of the Metropolis, held by Vendor six years. Gross receipts between £400 and £500 of which about £200 is taken in cash. House contains six good rooms, shop, &c. Rent, £40. An efficient introduction would secure to a doubly qualified gentleman a very large scope for practice.

Y 517. Established half a Century, a profitable COUNTRY PRACTICE, the whole of which can be transferred to a suitable gentleman. Average receipts are £500 a year, including appointments easily worked. There is no opposition within five miles. The house is a good old-fashioned family residence, fitted with modern conveniences; it contains ten rooms, and there is a large garden, meadow, stabling, orchard, &c. Rent, £35. No assistant necessary; one horse does the work. The patients consist chiefly of farmers who pay well. Midwifery fee, £1 ls. and mileage. There is a railway station within a short drive; and good shooting and hunting can be had in the vicinity.

NOTES IN OPHTHALMIC PRACTICE.

BY ARCHIBALD HAMILTON JACOB, M.D. T.C.D., F.R.C.S.,
Surgeon to the Dublin Infirmary for Diseases of the Eye and Ear.

No. I.

SECONDARY CATARACT.

THE term "Secondary Cataract" is strictly speaking a misnomer, and the pathological conditions to which it is applied are incorrectly described by it. In the great majority of cases the opacities of the lenticular capsule to which the name is given are not secondary formations, and in those instances in which the opacity is the result of a deposit occurring subsequently to the removal of the lens itself, the conditions cannot be at all truly called a cataract. Secondary cataract is, in fact, as I have said, either an opacity of the capsule of the lens or a pupillary obstruction caused by bands of lymph, resulting from inflammation which involves the iris. In many cases, especially those occurring in early life, cataract involves both lens and capsule, and the capsular portion of the opacity may easily be observed before operation, showing as an irregular chalky patch upon the milky or waxy back-ground of the opaque lens. It is now denied by Müller and others that the capsule itself can ever become opaque, and these writers maintain that the opacities result from the deposit of layers of new material and portions of altered lens material, but the distinction is not of any importance as regards treatment. Supposing the capsule to be uniformly transparent before the removal of the lens, it frequently becomes opaque afterwards—no doubt in consequence of an injury received in the progress of the operation or some slight inflammation supervening. This is a much more usual sequence of the operation for cataract by division than of any other procedure, and it is the opprobrium of that operation, and almost the only cause of failure to restore sight by that means. Lastly,

the name of secondary cataract has been applied to bands or threads of lymph passing across the pupil, the result of iritic inflammation after cataract operations. I have seen many of these latter obstructions as a sequence of those extraction operations which are accompanied by an iridectomy.

On the 20th of last month I removed, in the Dublin Eye Infirmary, two secondary cataracts—illustrations of the second and third forms of "Secondary Cataract" described above.

T. D., the first patient, was a country labourer, æt. 45. Many years ago his left eye had been operated on for soft cataract by another practitioner, but was now amaurotic and squinting. His right eye was operated on by myself in May, 1871, by my father's method of keratonyxis. The removal of the lens was successfully effected, and with a dilated pupil the sight was sufficient to enable him to work. But the centre of the pupil was occupied by a very white and dense tag of capsular opacity without any adhesion to the iris, which in the undilated condition of the pupil, completely obstructed vision. As soon as the entire lens had been absorbed, I made an attempt, according to the method usually pursued, to remove the opacity with the needle out of the field of vision, but though I was successful in doing so at the moment, it returned to the original position, and the vision was no better than before. At his request I determined now to extract the opaque capsule. Ether having been administered by Dr. John Morgan, I steadied the eye with the fixation forceps, and with the spear-shaped keratome incised about a sixth of the perimeter of the cornea. I then passed an iris forceps into the anterior chamber, and seizing the opaque tag of capsule twisted it from any adhesions which might exist by turning round the forceps twice or thrice between my fingers, and having done so, gently withdrew it. Having carefully disengaged the iris from the edges of the wound, and satisfied myself that it was well retracted within the globe, I closed the lids with court-plaster, applying no compress nor any bandage, and prescribed neither local application nor therapeutic treatment. The convalescence of the patient was unimpeded by any inflammatory symptom, and he returned to the country five days subsequently with as perfect vision as the absence of his lens would allow of.

The removal of a secondary cataract in this way, though apparently a simple proceeding, is one which is liable to very embarrassing accidents, and it is agreed by all authors, attended with a good deal of danger to the eye. Mr. Soelberg Wells remarks respecting it—"Formerly the favourite mode of operating was by the removal of the obstructing membrane. But this is falling more and more into disuse, as it often proves a very dangerous operation, and is far less safe than opening up the membrane by the needle" (which, it will be remembered, I had done without beneficial result), "which is attended by much less risk of setting up inflammation." The prognosis of the operation will depend almost altogether on the extent and strength of the synechiæ or adhesions of the capsule to the iris and the intimacy of its connexion to the vitreous body. In this case there were no synechiæ, but in a former patient I broke down the adhesions with the needle a week previously to the removal of the opaque capsule. In order to free the secondary cataract completely from its connexion with the vitreous body before drawing it out of the eye, I resorted to the manoeuvre of twisting the forceps two or three times after it had seized the capsule, and I think that it will be found that this proceeding, which is effected without the least disturbance of the intra-ocular structures, will effectually relieve the operator of the danger of pulling away a part of the vitreous, or causing a laceration or prolapse of the iris.

ETHER *versus* CHLOROFORM.

ON THE USE OF ETHER AS AN ANÆSTHETIC IN SURGICAL OPERATIONS;

AS A SAFER AND MORE EFFECTIVE AGENT THAN CHLOROFORM IN PRODUCING THE AVOIDANCE OF PAIN.

With a Description of an Inhaler, and the Mode of Administration.

By J. MORGAN, M.D., F.R.C.S.,

Professor of Surgical and Descriptive Anatomy Royal College of Surgeons, Dublin, Surgeon to Mercer's Hospital, &c.

I NOTED this day four patients I etherised. One, a very strong man, where extraction of a cataract (a) was performed. Insensibility was obtained in ten minutes; the pulse remained steady; there was no sickness of stomach; and the operation was most successfully and happily terminated—just as in a similar case which I etherised a few days previously.

Another vigorous patient, of 17, in four and half minutes sank quietly into insensibility with the most perfect result; pulse from 80 to 86; respirations increased six per minute. I occupied about five minutes in operating; and the patient emerged from insensibility equably and gently—there was no excitement or sickness.

Another, of 24, became influenced in ten minutes, with no excitement beyond bursts of laughter; there was no sickness of stomach. I occupied five minutes in operating; the recovery was most equable.

Another, of 30, became influenced in eight minutes, and fully so in ten minutes, with no excitement or approximation to convulsions, and no sickness. I occupied six minutes in operating.

In the last case I had used chloroform three times previously, and ether once; and in the second last case I had used chloroform five times, and ether once. In both, but in the second last more particularly, the convulsive stage under the use of chloroform was always very severe and protracted.

(a) By D. Jacob.

Ether produced *incomparably* superior results in every way, accompanied by a sense of much greater security. I particularly noted these instances, as I had observed the previous effects of chloroform on the patients.

It is but natural that we should examine with attention the expressed opinions of surgeons as to an agent which has been most used in America, the country which may be allowed to have been the birthplace of the application of anæsthetics in surgical practice. Since the time when Dr. Morton, so long since as 1846, introduced the use of ether as a "pain-destroyer," Ether has stood the test for the period which has since elapsed, and ether is still, in that country, the more universally adopted means of obtaining insensibility.

I find in the last very accurate surgical work which has issued from the press, 1871, the question of Ether *versus* Chloroform is thus reviewed (a):—

"Chloroform is more prompt in its effects; the patient is usually quieter while coming under its influence; it is less apt to cause vomiting; a smaller quantity suffices to produce anæsthesia, and the patient reacts more quickly when the inhalation is stopped. It, however, requires greater care in its administration than ether, and its use is attended with *much greater risk to life!* This statement gives my own estimate of the relative merits of these agents, and I believe corresponds pretty closely with the opinions usually entertained on the subject. It is right, however, to state that Dr. Lente and Dr. Squibb, of New York, believe that anæsthesia may be induced by means of ether, as quickly as can safely be done by means of chloroform, and with a quantity costing less, and weighing very little more than the requisite amount of the latter; and other writers have maintained that vomiting is, at least, as frequently caused by chloroform as by ether."

In support of the latter observation, I myself can refer to the cases I have just witnessed, and that in the last thirty patients I etherised, within ten days sickness of stomach occurred but in two, and in these instances, some food had been taken one hour and a half before operation.

"For my own part," says Dr. Asshurst, "I confess I prefer Ether in a very large majority of cases; it is certainly, I think, *safer* than chloroform, and is sufficiently convenient for almost every case that the surgeon is called upon to treat. There is *no danger*, as in the case of chloroform, of the vapour being too concentrated; indeed, some surgeons, as Dr. Lente, endeavour to prevent even the slightest admixture of air" (b).

We have thus reported, by the most recent authority, the value of the arguments for either chloroform or ether, "*Safety to life*" and the avoidance of those very unpleasant accidents, "deaths by chloroform," presenting the strongest claims in favour of Etherisation, and justifying the candid remark of Mr. Erichsen (c), of London, when he states,—"*The fatal consequences which have attended the employment of chloroform, have caused American surgeons almost entirely to trust to ether in preference. Ether is certainly a safer agent than chloroform, but few deaths having resulted from its administration; and the only argument in favour of the use of chloroform rather than ether is, that chloroform is the most convenient agent! its effects being produced more quickly, and no disagreeable smell being left, as in the case of ether.*" Fortified with such an opinion from so eminent an authority as Mr. Erichsen, M. Diday would be well supported in passing the condemnatory resolution I have already referred to, "that any surgeon using chloroform instead of ether as an anæsthetic would be culpable."

Surely, it would be a small solace to a husband for the death of a wife, or to a wife for that of a husband, to be told that chloroform, which caused the loss of what was held most dear, was used, simply because, while it was far more dangerous, "it was more convenient." Indeed, in a case of

(a) "Principles and Practice of Surgery." By J. Asshurst. P. 75.

(b) *Ibid.*, pp. 75-77.

(c) "Science and Art of Surgery," p. 17. London, 1869.

death by chloroform, it appears to me that legal if not moral culpability might be strenuously urged against the administrator, for using an agent admittedly *more dangerous* than another, simply on the ground as stated, and "the only argument" in its favour, that it was "*more convenient*." The question is thus becoming daily more serious and debatable.

The late American War furnished enormous opportunities of testing the merits of Ether. In one of the most recent and critical treatises on Military Surgery (a), the preference is given to ether, supported amongst other arguments by the fact that, taking the reports of the general hospital (Mass.), for ten years, 1850 to 1860, where Ether was exclusively used, "notwithstanding the greater severity of the cases (mostly railroad and street accidents) and the more crowded condition of the hospitals, the average mortality was substantially the same as before its introduction. This testimony demonstrates the superiority of Ether as compared with chloroform." "Ether, ought generally to be preferred to chloroform as being less liable to destroy life immediately."

Few more cogent arguments could be collected than this ten years' epitome of the successful result of ether, when it is remembered that these cases did not even occur in military practice, where healthy and active soldiers were the unfortunate sufferers, but in a general hospital, where cases of all varieties, and in diverse circumstances of life, were encountered. It may also be admitted that operations were undertaken with the assistance of Etherisation, which, previous to its introduction, would have been unattempted; yet, while pain was absolved by this "comparatively, though not absolutely, innocuous agent," as styled by Prof. Hamilton, the statistics prove that it in no way contributed to an increased mortality rate.

On inquiring as to the recent practice in the large American institutions, I find in the excellent and compendious Reports of the Boston City Hospital, 1870—including 1,113 operations on in-patients, and 1,062 on out-patients—that amongst all those reported, with such critical procedures as excision of the upper jaw, œsophagotomy, ligation of large arteries, including that of the arteria innominate, excision of the hip-joint, amputations, &c. Ether alone was invariably used, and no ill-consequence or apprehension has been noticed.

In Bellevue Hospital, New York, with something like 1,800 beds, chloroform has never been used for the last four years, with the many hundreds of operations necessarily constantly performed there. In the Charity Hospital, Blackwell's Island, New York, where Etherisation alone is used constantly, not hundreds, but thousands of cases have been submitted to its influence without one *contretemps*. This I have the authority of the Resident Officer for stating, as he himself administered the ether in a very large number of these patients (b); while, on the other hand, in the cases in which he saw chloroform used, namely, two cases of hernia, one of hare-lip, and one for repair of a bitten-off nose, there was always much reason for apprehension, and he witnessed the death of one of the patients from the effect of the chloroform, which was being given where an operation, though painful, but no way involving life (the formation of a nose), was about being performed; it was never commenced, as the patient, a strong healthy looking woman, of 35, died on the table, notwithstanding all the means anxiously and actively used for reanimation.

Dr. Mott is said to have preferred chloroform to Ether (c). Evidently, however, Dr. Mott failed to leave the impress of his preference behind him, as in neither of these Institutions—to both of which he was attached—has anything but Ether ever been used since his death. I have obtained the summary of one very remarkable case of a large aneurism of the thoracic aorta, treated by

galvano-puncture, at Bethove Charity Hospital, where Ether was used on several occasions without any ill consequences, and with a feeling of perfect safety, where chloroform would have been inadmissible. It is so remarkable that I append it in illustration.

Bridget Dillon, aged 57, an Irish woman, and comparatively strong; suffering from a large thoracic aneurism; submitted to the attempt of obtaining occlusion by the galvano-puncture; she was etherised, and came under its influence in about eight minutes; needles were introduced through the chest into the tumour, and connected with a current of seventeen cells. There was no pain or ill consequence whatever. On one occasion the use of the needle was tried *without ether*; but the pain was excruciating beyond endurance.

The whole question of the comparative use of the various anæsthetics has been lately very fully reviewed by Dr. W. Coles, who read an elaborate paper replete with overwhelming evidence, at the Medical Society of Virginia, this last session. The arguments in favour of Ether *versus* Chloroform are unanswerable when the great question of *danger to life* is considered. By combining the American statistics, collected by Dr. Andrews, of Chicago, and those of England, by Dr. Richardson, of London, we obtain the following general view of the absolute and relative mortality caused by the several anæsthetic agents in use:—

	Deaths.	Inhalations.	
Ether	4 to	92,815 .	or 1 to 23,204.
Chloroform	53 „	152,260 .	„ 2,873.
Mixture of Chloroform and Ether	2 „	11,176 .	„ 5,588.
Bichloride of Methylene	2 „	10,000 .	„ 5,000.

These figures the author regards as the most valuable and reliable that have ever been published in reference to the *mortality* in anæsthesia. They demonstrate a state of facts so absolutely at variance with the received opinions of five years ago, as to become *perfectly startling*. They indicate that chloroform is *eight times more dangerous than ether, twice as dangerous as a mixture of chloroform and ether*, and, as far as experience goes, it is *more dangerous than bichloride of methylene*.

In view of these facts the question arises—Will chloroform maintain its present popularity as an anæsthetic in surgery? We do not believe it will; unless some method, other than we have at present, is devised to lessen the risk dependent on its use, we cannot but think its popularity must decline. In the face of such figures as adduced, *chloroform cannot, and ought not, to supersede ether*. The inconveniences attending the use of ether are more than compensated for in the risks from chloroform (a).

Nothing can put the question in a plainer light. One death from ether in 23,204 cases reduces the risk to a nominal amount.

It is to be recollected that in Etherisation there is not the constant and harassing danger ever present; the surgeon is freed from the anxiety that more or less accompanies him into the operating chamber, and his attention can be altogether devoted to the operative procedure in which he is immediately engaged, not, as is too frequently the case, distracted by inquiries as to the condition of the patient, and the influence which the chloroform is exciting. Friends who are intensely interested, are relieved from an additional cause of anxiety which the occasional notice of "Death by Chloroform" may have impressed them with, while equal, if not greater, security of the avoidance of pain is secured, with *Eight times less danger*. Facts such as these cannot fail "to become perfectly startling," and deeply to impress a patient about precipitating himself into the mysterious sleep of insensibility.

With such convincing statistics from the mother country of anæsthetics, where Ether is used, and from Great

(a) Dr. Hamilton, Professor of Military Surgery, Bellevue Hospital, New York, p. 621.

(b) Dr. Godon.

(c) Hamilton's "Military Surgery," p. 612.

(a) Hay's American Journal, April, 1872, p. 488.

Britain, where Chloroform was introduced and is used,—with the opinion expressed in the latest standard work (a) from the former country of unalterable faith in the use of Ether,—with the opinion, also, of the author of a standard work (b) in great Britain, where, though chloroform is the more largely used, its danger is admitted, and the only argument adduced in its favour is that of convenience. In the face of the discussion at present being agitated on the Continent (c), and with the occasional reports which crop up of deaths from chloroform, the dangers of chloroform, and the hairbreadth escapes from chloroform, it is evident that its popularity must wane when calmly contrasted with Ether as an anæsthetic agent.

The surgeon who makes use of chloroform will employ an agent not only *eight times more dangerous* than Ether, but actually the *most dangerous* of the other agents in use.

Should he not have put these issues before the patient, and should any casualty occur, his responsibility may be indeed seriously brought into question.

(To be continued.)

Special Report

ON

DISEASES OF THE THROAT.

Edited for the "MEDICAL PRESS AND CIRCULAR."

By PROSSER JAMES, M.D., M.R.C.P.,

Physician to the Hospital for Diseases of the Throat and to the North London Consumption Hospital; Lecturer on Materia Medica and Therapeutics at the London Hospital.

Laryngoscopy. Introductory. Early use of Mirrors by Dentists. Reflected Light. Forms of Apparatus. Shapes of Laryngeal Mirrors. Supports of Reflectors. The Light. Forms of Lamps. Direct Light. Concentrators.

LARYNGOSCOPY ($\Delta\lambda\rho\upsilon\gamma\acute{\iota}\sigma\kappa\omicron\pi\acute{\alpha}\tau\omicron$) is the art of examining the interior of the larynx. This is accomplished by means of a mirror sometimes called the laryngoscope, but this name is more usually assigned to the complete apparatus used to obtain a view of the larynx.

It is obvious that a dark cavity situated in such a position as the organ of voice can only be seen in the living person by the aid of a reflector. In fact, in the practice of laryngoscopy we do not look at the interior of the larynx itself but at its image in a mirror.

The laryngoscope, then, is only a contrivance to enable us, so to say, to see round a corner, and it is a little remarkable, considering the length of time that reflectors have been employed for similar purposes, that physicians should not long ago have availed themselves of the same principle.

In its very simplest form the laryngoscope may be said to exist in the mirrors used by dentists, and indeed the earliest efforts at laryngoscopy consisted in the use of such mirrors mounted on a long handle. The difficulty was so to place the patient as to allow sufficient light to fall upon the mirror, and practically this was not attained until a second mirror was used to reflect the rays and direct them upon the first.

This was essentially the starting point of laryngoscopy. Nevertheless, the simpler method of utilising the direct

rays of light involves the principle of the laryngoscope, and those who persevered in the attempt thus to obtain a view of the larynx are entitled to the credit of having in some degree contributed to the progress of the art.

A second great step in advance was the employment of artificial light, for this being always at command experiments could be carried on at any hour and in any room.

As soon as this step was taken the modern laryngoscope may be said to have been completed; for the many variations in the shape of the mirrors, the mode of supporting the reflector or the lamp, can scarcely claim to do more than render the apparatus more convenient.

This brings us to a consideration of the several forms of laryngoscope in common use. To describe them it is necessary to take each portion separately.

The most important part of the apparatus—the laryngoscope itself, so to say, is the faucial or laryngeal mirror, as it is designated. It consists of a plane reflecting mirror mounted on a long stem. It may therefore be made of silvered glass, of burnished steel, or of any other good reflecting surface. Steel, however, is very apt to rust, and ordinary looking-glass is therefore most commonly used.

The shape of these mirrors has been discussed with some gravity, but is a matter of little importance. Some prefer them round, others think square, with the corners rounded, more convenient. Others maintain oval ones to be best. It is easy to see with either. Where the tonsils are enlarged an oblong shape may be essential, and in a few other cases it is very convenient.

The shape of the stem is equally a point of little importance. The mirrors may be mounted on a handle, similar to an ordinary pen-holder, or they may be furnished with any other stem. The following illustrations show the more common forms. The square mirrors are preferred by many French authorities, and these illustrations are taken from them. The round ones with the handle are an English model, made by Maw, who also supplies the French shape.

FIG. A.

(a) Anshurst.

(b) Erichsen.

(c) Société de Médecine.

FIG. B.

It will be seen that a single handle is made to serve by means of a screw for three sizes of mirrors. This is convenient for portability. To increase this convenience I have had them made to slide in the whole length of the handle, an improvement that has been adopted by many. It will be seen that the mirrors are mounted at angles of about 120 degrees. This is the most convenient for general use, and it can easily be varied by bending the flexible stem to suit special cases. In hospital practice it is better to have a large number of mirrors, mounted at different angles, and of all sizes, but for ordinary cases the three sizes depicted, and the angle mentioned will suffice.

The next part of the apparatus is the reflector. This is only a concave mirror, by means of which we can divert the light wherever we please. Whether it should be perforated in the centre, like the ophthalmoscope, has excited some controversy. One of the earlier shapes is seen in this cut.

C.

FIG. D.

This is still made by Maw, together with an additional lens (E) so as to serve as an ophthalmoscope.

FIG. E.

The mode in which the reflector is supported is the next point. I have tried all plans, and am not at all particular which I now use. In the early days of laryngoscopy I had a reflector mounted on a distinct stem to stand on a table, and still sometimes employ it in the consulting room. But it is not portable in comparison with other modes. Czermak had a mouthpiece to hold it by the teeth, and Messrs. Weiss made me an instrument on his model, which I have used for many years. It is not easy for those whose teeth are defective. Semeleder, Stellwag, and others had the reflector mounted on a pair of strong spectacle frames, an arrangement adopted by many others, the frame having been rendered lighter by Mackenzie's suggestion to dispense with the upper rim. These frames can also be fitted with a suitable concave or convex lens to suit the sight of any operator, or with a pair of different focus for persons who are very binocular. This I consider important, as many persons require a correcting lens. Indeed, in teaching, I become more and more convinced of the importance of the learner adopting such a lens as may be desirable, even though his vision be such as he may have previously considered normal.

Frames of this kind have been lately furnished by Messrs. Mayer and Melzer to pupils at the Hospital for Diseases of the Throat.

Messrs. Arnold also made them for me at an early period, and now keep in stock a case which the following illustration shows to be very portable.

FIG. F.

Schrötter prefers Kramer's forehead-band, and in this he is strongly supported by Dr. Johnson, who also dispenses with the central perforation.

That the forehead-band forms a good support, and is easy to use, is undeniable. This illustration will serve as a sufficient description.

FIG. G.

(To be continued.)

Foreign Medical Literature.

CONTRIBUTIONS TO THE PATHOLOGY OF THE BLOOD.

BY PROF. S. STRICKER, of Vienna.

(Translated for the MEDICAL PRESS, by E. B. BRONSON, M.D., from the *Archiv. für Dermatologie und Syphilis*, II. Heft, 1872.)

(Continued from page 97.)

EXAMINATION.

AFTER what has been related it will no longer surprise any one when I declare that in a large number of preparations I have followed the fate of the form-elements visible in fresh blood, through several days. Based upon such observations I can now declare that those bodies which I have conjecturally indicated as products of coagulation, or as detached bits of protoplasm, as a rule, after culture of some twenty-four hours, disappear from view. It is for our purpose indifferent whether my explanation of the corpuscles is correct or not. For the only question which here concerns us is whether these bodies are identical with those discovered by Losterfer, or whether the former are produced by the latter. In either case it were then evident that Losterfer's corpuscles are to be found in the fresh blood of normal as well as of diseased individuals. This, however, proves not to be the case. In a number of fields in fresh preparations I have registered with precision all occurrences in connection with position or form, and have satisfied myself with all positiveness that those bodies visible in fresh blood, as described at page 96, were with undefined contours and quite pale, still to be seen, while round about them, new granules before not visible came in view, which at successive observations appeared larger and larger, till finally they presented such distinctly marked appearances, that there remained no doubt that they were the corpuscles of Losterfer. A discussion of the manner in which the corpuscles visible in fresh blood perish cannot be here entered upon, nor does such a discussion pertain to the question here in hand.

The preliminary question which I proposed in the beginning—viz., whether Losterfer's corpuscles are to be found in fresh blood—is already in part answered. I am able, however, to report an observation which still more conclusively settles the matter.

In the month of March of this year there was a patient in the department for syphilis, under the charge of Prof. Zeissl, uncommonly favourable to my investigation. It was the case of an individual, twenty-two years of age, badly nourished, who had for four months suffered from

syphilis. There had been at first an ulcer, then followed an exanthem and iritis. I took a small quantity of blood from the *vola manus*, prepared several specimens, and after twenty-four hours found the borders of the specimens perfectly studded with the corpuscles I was seeking. A second series of preparations exhibited the same result. In a third series no result was obtained for the first thirty-six hours, and the bodies did not appear in view till forty-eight hours had elapsed.

Just at this time we had ceased to heat our working room, notwithstanding the temperature was pretty low. The consideration of all the circumstances which could have occasioned this want of success led me now to take into account the temperature. The following day I had my room heated up to 22° C., took new specimens, and having examined them throughout, made careful note of several points situated near the periphery. After a lapse of some three hours, the corpuscles were present in great number. Some of them were so large, however, that I was forced to the following alternative: Either in spite of all my previous observations I have been deceived, and the corpuscles were after all present in the fresh blood, and escaped my observation, or their growth is in this case exceedingly rapid, and I must be able to directly observe it.

The next day I took still another preparation, had my room heated as on the previous day, brought a certain point near the periphery under the immersion lens No. 10 (Hartnack), and took observations. About thirteen minutes had passed since the blood had been taken from the patient, when it seemed to me I saw in the otherwise clear field under observation several granules. In the course of ten minutes more these granules had taken such a certain character, that I could now precisely mark their situation. At the same time it appeared to me that in the same islands numerous new granules emerged. I was unable continuously to regard them, since I was obliged from time to time to look away for the relief of my eye; but I had so precisely marked certain granules according to their position, that I recognised them at once as often as I again looked. A half hour after the first emerged granules had become so large that I could recognise them with certainty as being the ones sought. At the expiration of an hour and a half the first granules had grown to about the size of a small pus-corpuscle, while the whole field was beset with similar but smaller granules. There remained no longer the slightest doubt that I had the corpuscles of Losterfer before me. They had sprung up in a clear field and grown under my eye.

On the following day I repeated the experiment. I did not have the room heated, however, but laid the preparation upon the heating table, which I warmed up to 25° C. The result was the same. I repeated the observations made upon the previous day with perfect positiveness. What I had concluded from the numerous observations which I had previously made, but extending over several days, was now supported by direct observation; and the preliminary question was answered with all certainty.

Let us now turn to the first prime question, what is the nature of these bodies in question? The bodies are either organisms or anorganisms. From what up to this point we know of them, we are able to decide positively for neither of these two possibilities. We know of them that they grow. But growth alone is no sufficient criterion to justify a positive decision.

Losterfer has stated that the corpuscles have bud-like processes (Knospen). This statement is also correct. But I have learned by means of very positive observations that certain of the buds arise not from growth, but by apposition.

In the perfectly fresh state most of the corpuscles are spherical, and seen by No. 10, or even No. 15, immersion appear homogeneous. Now, I succeeded in directly observing how a smaller corpuscle which lay for a considerable time in the vicinity of a larger, approached the latter

and then rested as a detached head upon it. After some time the contours were altered in such a way that the constricted interval, sharp as seen in section, was changed into two concave sinuosities, one on each side; then the sinuosities were smoothed out, and I had a club-shaped body; the extremities were then gradually drawn in, and the club became a ball.

I could not say, of course, whether all the corpuscles provided with processes arose in this way. But it was enough that I had observed at all such a mode of origin. It was enough to be able to assert that the completely formed processes prove nothing at all with regard to the life of these structures.

Lostorfer has also stated that the corpuscles grow out in ascidia. I have but a single time seen a corpuscle with a long attached stem. But on this single occasion I have also observed again the mode of origin of the process with certainty. It was by means of the juxtaposition of three smaller bodies which at the commencement of the observation lay quite near to each other, and contributed to form one large one. The constricted intervals were smoothed out, and the homogeneous stem projecting from the large corpuscle was completed. We can, then, neither from the buds nor from the stems which the corpuscles exhibit, infer their organisation.

My observation of the mode of origin of the buds leaves the phenomenon of growth, spoken of above, in a still more doubtful light. If it be once made out that the smaller corpuscles become blended with the larger, why should it not be that the smaller grow through smaller ones still being annexed to them? It is true it is impossible to see that the corpuscles whose growth I have watched have grown by means of apposition, but that signifies but little.

I have at any rate ascertained that the corpuscles have sprung up into view within the field of the microscope, and, indeed, as structures so minute that it was scarcely possible to see them. Hence it must be that there are corpuscles of such a minuteness there. Yes, and still more. It is fair to assume that they were at first without the range of vision, and first became visible by growth. What hinders us now from supposing that these corpuscles which we have seen grow under our eyes do grow by apposition of invisibly minute bodies? One may object that this is a process of which we know not a single instance except in crystalline bodies. But do we know of an instance where an organism grows so rapidly as must be the case when an organism in the course of an hour from beyond the range of vision with immersion lens No. 10, grows till it attains the size of a very large nucleus?

It seems to me, therefore, to be established that from the growth alone we are able to conclude nothing with regard to the nature of the corpuscles. So much only is established that we have to do with a quite unknown structure.

I have meantime learned still another fact which led me still nearer to an appreciation of the nature of these bodies. I have learned, namely, that the structures in question react differently under chemical action, immediately after their development upon the heating table, to what they do when kept for several days as bodies of considerable size in the incubating chamber. In the latter case they resist the action of acids and alkalis; they shrivel a little, but are not destroyed. Shortly after they have developed they are destroyed by acids and alkalis, and even by water.

For this reason also it is important that at the commencement of the incubation the preparation take up no water. If the bodies have once developed, they maintain themselves for days, even when the blood corpuscles are destroyed by the admission of vapour.

The peculiarity here described could be very well explained under the supposition that the corpuscles in question are organisms. We had then the state of youth and age before us, and it would in every particular cor-

respond to the conditions of youth and age in animal cells. In the youthful state we had bodies with relatively soft external layers, while in the later stages the more outer layers had become hardened.

If, however, we assume that the corpuscles be not living, then they must at least consist of colloid matters, and so the possibility remains that their outer layers in the course of days may become hardened.

I was on the point of terminating my investigations with regard to this question, with the indefinite results which have been thus far depicted, and only wished once more to make the trial as to whether it might be possible by means of more strongly heating the specimens, to collect any practical experiences. I had already made the trial before with the blood of another patient and the corpuscles gradually becoming visible, were lost in formation of vacuoles. Now I desired to learn more precisely the mode of origin of these vacuoles.

Meantime, having with all precaution very slowly warmed up to about 33° C. a preparation of blood from the above-mentioned patient, a remarkable sight was presented to my view. A perfectly clear field was in the course of some fifteen minutes so thickly studded with the finest granules, that I was obliged to think a precipitate had suddenly formed. It was not possible to watch any particular corpuscle in its growth. Their number was too great, they lay too near to each other, so that each time I looked away I was unable to judge as to whether the corpuscle just fixed upon was identical with one regarded before. One thing, however, was not to be mistaken; the number of the quite distinctly visible corpuscles gradually increased, and some of them were soon so large, that I could recognise them with certainty as the corpuscles in question. It was at the same time apparent that a large number of them were provided with appendices. I now fixed in my eye such a corpuscle as long as I could look continuously in the microscope and found that two corpuscles, a larger and a smaller soon approached each other, and then separated again. After so fatiguing an observation I was obliged for a short time to rest, and at each new look I must, for the reasons given above, take a new pair, of which there were many within the field. At the same time my attention was called to the fact that at different points of the field each pair of corpuscles lying near each other were connected by extremely delicate fibres. I then saw that every two such corpuscles conducted themselves in oscillatory movements in such a way towards each other as if there were a firm connecting bridge between the two. While they were in motion I was enabled also, by means of alteration in the light, to see the thin and structureless fibre of connection. Further, I observed with all certainty, how two such bodies first slowly approached each other, and then again separated, again approached, again parted, and finally rapidly left each other.

The number of the granules apparently increased, the field was now thickly beset with them, but there was no considerable growth; the corpuscles remained much smaller in size than they had attained by slow warming to 22°—25° C. In spite of attentive observation, I was not enabled this time to observe the blending of two corpuscles. I had seen in very many cases the band of separation between two corpuscles become broader and shorter, so that the two seemed sometimes to represent one body, with a rather wide mark of division.

After the phenomena here described had repeated themselves on the following day in the blood of the same patient, and under the same conditions, I regarded the prime question as answered. According to the information up to the present time at our disposal, we can explain the appearance of the repeated approach and separation of two corpuscles only on the supposition that the fibres of connection between them are contractile, that the corpuscles themselves are organisms.

(To be continued.)

STUDENTS' COLUMN.

SYNOPTICAL REVIEW OF THE OFFICIAL PREPARATIONS OF THE BRITISH PHARMACOPEIA.

BY W. HANDSEL GRIFFITHS, Ph.D., L.R.C.P.,
L.R.C.S. Edin.,

Assistant-Librarian Royal College of Surgeons in Ireland.

LIQUORS (SOLUTIONS).

THERE are thirty-seven formulæ for the preparation of these in the Pharmacopœia. With two exceptions (Liquor Antimonii Chloridi and Liquor Epispasticus) they may be defined as consisting of substances, sometimes gaseous, dissolved in, or diluted with, water.

They may be conveniently divided into groups as follows:—

CLASS I.—SOLUTIONS OF METALLOIDS.

Liquor Iodii.
Chlori.

Liquor Iodii.—Prepared by dissolving 20 grains of iodine in 1 ounce of water by the aid of 30 grains of iodide of potassium. The solubility of iodine in water is greatly increased by the presence of the iodide.

Liquor Chlori.—This is a solution of chlorine gas in half its volume of water. It is prepared by passing the washed gas (made by the action of hydrochloric acid on black oxide of manganese— $4HCl + MnO_2 = 2Cl + 2H_2O + MnCl_2$) into water.

As this solution is liable to be decomposed by light and exposure to air, at first into hydrochloric and hypochlorous acids, and ultimately into hydrochloric acid and oxygen, it is directed to be preserved in green glass bottles well-stoppered, and to be kept in a cool, dark place.

Liquor Chlori is of a yellowish-green colour with a strong odour of chlorine; it instantly discharges the colour of a dilute solution of sulphate of indigo. Its specific gravity is 1.003. If no fixed impurities are present there will be no residue on evaporation. The Pharmacopœia directs the following quantitative test, which indicates that the proper amount of chlorine (2.66 grains to the fluid ounce) is present:—When a solution of 20 grains of iodide of potassium in an ounce of water is added to a fluid ounce (439 grains by weight) of the *Liquor Chlori*, the mixed solution acquires a deep red colour, owing to the liberation of iodine, thus:— $KI + Cl = KCl + I$. On adding to this coloured solution 750 grain-measures of the Volumetric Solution of Hyposulphite of Soda, the colour is discharged, owing to the reaction of the free iodine on the soda salt forming colourless iodide of sodium and tetrathionate of soda, thus:—

CLASS II.

Solutions of Alkalies or Alkaline Earths whose neutralising power is estimated by the amount of Volumetric Solution of Oxalic Acid which they are capable of saturating (a).

- Liquor Ammonia Fortior.
- „ Ammonia.
- „ Potassa.
- „ Soda.
- „ Calcia.
- „ Calcia Saccharatus.

We will consider consecutively the method of preparation, neutralisation, strength, specific gravity, and tests for purity of the foregoing.

(a) 1,000 grain-measures of the Volumetric Solution of Oxalic Acid contain half an equivalent in grains (63) of Oxalic Acid and will therefore neutralise an equivalent in grains of an alkali or alkaline carbonate.

Preparation.

Liquor Ammonia Fortior is made by passing ammoniacal gas (made by the action of slaked lime on chloride of ammonium—

into water contained in a Woulf's bottle under pressure until the requisite strength is attained.

Liquor Ammonia is simply made by diluting one part of the strong liquor with two parts of water.

Liquor Potassa and **Liquor Soda** are solutions of the hydrate in water, and are both made by the action of slaked lime on the carbonate

In each the carbonate of lime is deposited, and the supernatant liquor is directed to be decanted or drawn off with a syphon, as filters are acted upon by it.

Liquor Calcia is very simply made by saturating water with slaked lime, and decanting or drawing off with a syphon (for the same reason as in *Liquor Potassa*) the clear solution.

Liquor Calcia Saccharatus is made by digesting for some hours a mixture of 1 part of slaked lime and 2 parts of refined sugar in 20 of water.

Slaked lime is very sparingly soluble in water, requiring 732 parts of cold, and 1,500 of boiling water. Sugar greatly increases the solubility of lime, so that the saccharated solution is fourteen times stronger than the simple solution, a fluid ounce of the latter containing only half a grain of lime.

Liquor Potassa, **Liquor Soda**, and **Liquor Calcia** all strongly attract carbonic acid from the atmosphere, and hence they are to be kept in well stoppered bottles; they are furthermore directed to be kept in green glass bottles, the reason of which is that they exert a solvent power over the oxide of lead of white glass.

Neutralisation.

	Grains weight.	Grain-measures of Vol. Sol.
<i>Liquor Ammonia Fortior</i>	52.3	= 1,000
<i>Liquor Ammonia</i>	85	= 500
<i>Liquor Potassa</i>	462.9	= 482
<i>Liquor Soda</i>	458.0	= 470
<i>Liquor Calcia</i>	4,380.0	= 200
<i>Liquor Calcia Saccharatus</i>	460.2	= 250

Strength.

Liquor Ammonia Fortior.—32.5 (of NH_3) per cent. One fluid drachm contains 15.83 grains.

Liquor Ammonia.—10 (of NH_3) per cent. One fluid drachm contains 5.2 grains.

Liquor Potassa.—5.84 (of KHO) per cent. One fluid ounce contains 27 grains.

Liquor Soda.—4.1 (of NaHO) per cent. One fluid ounce contains 18.8 grains.

Liquor Calcia.—One fluid ounce contains half a grain of CaO .

Liquor Calcia Saccharatus.—One fluid ounce contains 7.11 grains of CaO .

Specific Gravity.

<i>Liquor Ammonia Fortior</i>	0.891
<i>Liquor Ammonia</i>	0.959
<i>Liquor Potassa</i>	1.058
<i>Liquor Soda</i>	1.047
<i>Liquor Calcia Saccharatus</i>	1.052

Tests for Purity.

Liquor Ammonia Fortior:—

1. When diluted with four times its volume of water it gives no precipitate with—

- (a) Solution of lime = absence of carbonate;
- (b) Oxalate of ammonia = absence of lime;
- (c) Sulphide of ammonium = absence of oxide of copper;
- (d) Ammonio-sulphate of copper = absence of sulphide of ammonium.

2. When treated with excess of nitric acid it is not rendered turbid by—

- (a) Nitrate of silver = absence of chlorides ;
- (b) Chloride of barium = absence of sulphates.

When "pyrrol" exists as an impurity of the commercial liquor, it may be detected by affording a red colour with pure nitric or sulphuric acid.

Liquor Potassæ and *Liquor Sodæ*.—The following tests are directed for both of these solutions :—

1. No effervescence with diluted hydrochloric acid.
2. Mixed with an equal volume of distilled water there is no precipitate with—

- (a) Solution of lime = absence of carbonate ;
- (b) Oxalate of ammonia = absence of lime.

3. Treated with excess of diluted nitric acid and evaporated to dryness, the residue forms with water a nearly clear solution, which may be slightly precipitated by—

- (a) Chloride of barium = trace of sulphides ;
- (b) Nitrate of silver = trace of chlorides ;

but is merely rendered turbid (or unaffected in the soda solution) by—

Ammonia = trace of alumina.

Liquor Ammonia Fortior is employed in the preparation of *Ammonia Phosphas*, *Linimentum Camphoræ Compositum*, *Liquor Ammonia*, *Liquor Ammonia Citratis*, *Spiritus Ammonia Aromaticus*, and *Tinctura Opii Ammoniata*.

Liquor Ammonia is used in *Linimentum Ammonia*.

Liquor Calcis enters into the formation of *Linimentum Calcis*, *Lotio Hydrargyri Flava*, *Lotio Hydrargyri Nigra*, and is used in making *Argenti Oxidum*.

CLASS III.—EFFERVESCING SOLUTIONS OF ALKALIES.

Liquor Lithiæ Effervescens.

" *Potassæ Effervescens*.

" *Sodæ Effervescens*.

These are made by passing as much carbonic acid gas (generated by the action of sulphuric acid or chalk) as possible, under a pressure of seven atmospheres, into a solution of 30 grains of the bicarbonate (or in the case of Lithia 10 grains of the carbonate) in 1 pint of water. They all effervesce strongly when the containing vessel is opened owing to the escape of carbonic acid gas.

The following are the tests directed :—

Liquor Lithiæ Effervescens.—10 fluid ounces evaporated to dryness yield 5 grains of white residue, which answers to the tests for carbonate of lithia.

Liquor Sodæ Effervescens.—10 fluid ounces boiled for five minutes require for neutralisation 178 grain-measures of the volumetric solution of oxalic acid.

Liquor Potassæ Effervescens.—10 fluid ounces boiled for five minutes require for neutralisation 150 grain-measures of the volumetric solution of oxalic acid.

Five fluid ounces evaporated to one-fifth, and 12 grains of tartaric acid added yield a crystalline precipitate (of acid tartrate of potash) which, when dried, weighs not less than 12 grains.

CLASS IV.—CHLORINATED SOLUTIONS.

Liquor Calcis Chloratæ.

" *Sodæ Chloratæ*.

Liquor Calcis Chloratæ is prepared by digesting 1 pound of chlorinated lime in 1 gallon of water. Hypochlorite of lime, chloride of calcium, and a little caustic lime are dissolved, but any carbonate of lime which may be present, and excess of caustic lime are thrown down and are to be separated by a calico filter.

Liquor Sodæ Chloratæ is a mixed solution of hypochlorite of soda, chloride of sodium and bicarbonate of soda, and is known as "Labarraque's Disinfecting Fluid." It is made by passing washed chlorine gas (made by the action of hydrochloric acid on black oxide of manganese) into a solution of 12 ounces of carbonate of soda in 36 ounces of water. By the action of chlorine on the solution

of the carbonate of soda, hypochlorite of soda, chloride of sodium, and bicarbonate of soda are formed, thus—

Hypochlorite of Soda.

The following are the tests directed, the explanation of which are given under *Liquor Chlori*:—

Liquor Calcis Chloratæ.—One fluid drachm (80 grains by weight) added to a solution of 20 grains of iodide of potassium in 4 ounces of water, and acidulated with 2 drachms of hydrochloric acid, gives a red solution, which requires for the discharge of its colour 500 grain-measures of the volumetric solution of hyposulphite of soda, corresponding to 13 grains of chlorine in a fluid ounce.

Liquor Sodæ Chloratæ.—One fluid drachm (70 grains by weight) added to a solution of 20 grains of iodide of potassium in 4 ounces of water, and acidulated with 2 drachms of hydrochloric acid, gives a brown solution, which requires for the discharge of its colour 500 grain-measures of the volumetric solution of hyposulphite of soda. By the mutual reaction of *Liquor Sodæ Chloratæ* and iodide of potassium in an acid solution, iodine is liberated, thus—

Liquor Sodæ Chloratæ has an alkaline reaction, due to the presence of the bicarbonate ; it derives its property of bleaching vegetable colours from the chlorine. On adding hydrochloric acid to it effervescence ensues, owing to the evolution of carbonic acid gas and chlorine, and a solution is formed which gives no precipitate with perchloride of platinum indicating the absence of potash. It should give no precipitate with oxalate of ammonia indicating the absence of lime.

Liquor Sodæ Chloratæ is contained in *Cataplasma Sodæ Chloratæ*.

SPECIAL REPORTS ON FOODS,

INCLUDING DIFFERENT KINDS OF

FARINACEOUS PREPARATIONS FOR INFANTS AND INVALIDS,

MEAT EXTRACTS, AUSTRALIAN MEATS, &c.,

Together with reliable Chemical Analyses by
Competent Professors.

[PREPARED EXPRESSLY FOR THE "MEDICAL PRESS AND CIRCULAR."] —

REPORT ON THE FARINACEOUS FOODS NOW BEING ADVERTISED AND LARGELY USED FOR DIETETIC PURPOSES.

(Continued.)

In concluding our reports upon the farinaceous group of foods examined, it may be as well to classify them.

The dietetic classification into nitrogenous substances, fats (hydrocarbons), sugar starch, &c. (carbo-hydrates), and the so-called regulators or compounds not capable of oxidation will be found the most convenient form under which to consider these substances.

Four of the foods examined may be viewed as pure starches or carbohydrates ; the second of these consists of rice starch, all the remainder being maizes, or Indian corn starch—viz. :—

Brown and Polson's Corn Flour.

Coleman's British Corn Flour.

Duryea's Maizena.

Kingsford's Prepared Onwego.

These are all retailed at the same price and are all good and pure. We have three preparations purporting to be the glutinous part of wheat—viz. :

- Bullock's Semolina.*
- Mayar's Semolina.*
- Kean's Spanish Semolina.*

These contain variable proportions of starch (see analyses), but still are genuine preparations of the glutinous part of wheat. The semolinas are about the same price as the starches, with the exception of Bullock's, which is dearer. It is certainly, however, an exceptional preparation as regards the per centage of gluten. In fact we have never examined a semolina so rich in that substance. Another group of foods, five in number, may be specified as those in which both the nitrogenous food and starch are included—viz. :

- Chapman's Entire Wheat Flour.*
- Densham's Farinaceous Food.*
- Hard's Farinaceous Food.*
- Neave's Farinaceous Food.*
- Ridge's Patent Food.*

These are all wheat preparations. The first and two last are retailed at one shilling per pound, the remainder at two shillings. They are all supposed to have been submitted to special processes (in some cases patented processes); by which they are rendered more easy of assimilation. Therefore, although at first sight it might appear that some of these foods are rather dear, due allowance must be made for the rights of the inventor or patentees. It is self evident, however, that such preparations can never become general articles of food, except for invalids and young children.

The next group is similar to the above, except that they contain diastase introduced in the form of malted barley for the conversion of the starch into glucose, or the starch has already been converted thereby. They are five in number—viz. :

- Evan's Malt Extract.*
- Hoff's Malt Extract.*
- Hooper's Food for Infants.*
- Mellin's Liebig's Food.*
- Savory and Moore's Food for Infants.*

Two of these are fluid extracts (Evan's and Hoff's preparations), one is a dry granular extract (Mellin's preparation), whilst the other two are mixtures of the malt and wheaten meal. These are sold respectively at 1s. and 1s. 4d. per pound. Mellin's Extract 3s., Evan's at 2s., and Hoff's at 1s. 9d. As good malt yields nearly half its weight of extractive matter after the conversion of the starch, and if we take the alcohol present in Evan's fluid extract as representing starch, we find that this preparation represents about its own weight of malt, and that Hoff's preparation is much less than half this strength; considering its price, this is an inferior preparation. Mellin's extract might at first sight appear dear, but it must be borne in mind that it is actually a dry extract, representing a very considerable quantity of the original cereals from which it is prepared. The other preparations examined were :

- Robinson's Prepared Barley (Pure), 8d.*
- Robinson's Prepared Groats (Pure), 8d.*
- Sea Moss Farine (pure, but exorbitant in price), 4s per pound.*
- Barry du Barry's Ixvalenta, 3s. (chiefly Lentil Meal).*

The two first have special applications and speak for themselves. We shall say nothing further of the two latter as we have no intention of recommending their use and their characters have been already described.

The natural standard for infant's food must of course be the mother's milk, and failing in this we naturally make use of the cow's.

The relative composition of these two milks will vary under different circumstances, and it would seem as if even the complexion of the mothers materially affected the composition of the milk, but at the same time will equally affect the constitutional peculiarities of the offspring. The following will, however, we think, fairly represent the peculiarities of the two milks :—

	Human.	Cow.
Sugar	4.3	3.8
Casein	3.9	4.5
Fat	3.3	4.38
Salts23	.66

Solid ingredients in the } 11.73
1,000 } 13.22

We thus see that although specimens of milk either of human or otherwise, may vary considerably, yet, as a rule, the human milk is not nearly so rich as cow's, except as regards the sugar. Thus, the nearest approach to human milk would be by the addition of $\frac{1}{4}$ water, but unfortunately it still lowers the sugar without altering the relative proportions of casein. Thus, three parts cow's milk and one of water gives the following :—

Sugar or Carbo- hydrates	2.82	with the addition of two per cent. starch.	4.82
Casein	3.35		3.35
Fat	3.28		3.28
Salts	0.49		0.49
	9.94		11.94

So that we see that the nearest approach to mother's milk that we could get would be three parts cow's milk, one part water, and two per cent. of arrowroot or sugar. Such a mixture would represent an extremely rich human milk nearly in the same relative proportions. We are here speaking of the ordinary milk of the mother not colostrum or even the second week's milk. But if the infant's stomach has a horror of any of the substance present in its food it is the casein and fatty substances. Its chief digestive power is salival, and it is really wonderful to see the immense quantity of liquid starch that a few drops of saliva will instantly, even at a low temperature, convert into sugar. This can be beautifully demonstrative in a test-tube by iodine and potassio-tartrate of copper tests. Thus, we cannot give an infant diet too weak in reason, the only class of foods it is tolerant of in excess being the sugars and starches. As the being progresses in years then comes in the foods richer in proteinic compounds. The nitrogenous food will be always essential, the requisite amount being chiefly dependent upon the mental and bodily life of the consumer. They must, however, in all cases be presented in a form capable of digestion and assimilation.

In conclusion, we must speak in special commendation of Brown and Polson's "Corn Flour," Bullock's "Semolina," Mellin's "Liebig's Food," and Evans' "Malt Extract." To Messrs. Brown and Polson would seem due the credit of having first introduced into this country the maize in a desirable form as food. The others are exceptional preparations, and have been thoroughly described in their proper places. It should be borne in mind in connection with Bullock's Semolinas and the other protein foods, that wheat gluten is one, if not the most easily assimilated, of all the nitrogenous compounds.

The semolinas and the group of foods commencing with Chapman's "Entire Wheat Flour," are good preparations, and should be recommended by the medical man according to his own judgment, based on the idiosyncrasy and surroundings of the would-be consumer.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 7, 1872.

THE ADULTERATION SHAM.

THE *Pharmaceutical Journal* mentions with some exultation that the Council of the Society has been successful in the endeavour to obtain from the Government some modification of the stringency of the Adulteration Clause of the Public Health Bill in favour of persons who merely adulterate by dilution. The Pharmaceutical Society considers that one part of clause 2, which provided that "every person who shall sell as pure and unadulterated any article of food or drink or any drug which is adulterated or not pure" should be liable to a penalty of twenty pounds and other inconveniences, was, if carried out, sufficient to make the words "pure and unadulterated" a terror to all sensible men.

A deputation of the society, says the *Pharmaceutical Journal*, sought an interview with the Marquis of Salisbury, who has charge of the Bill, to urge their objections to certain features of it as it stood; and, fortunately, they succeeded in obtaining his consent to the modification of one or two of its most obnoxious points.

It will occur to many of our readers that the word "pure," in the penal clause, when applied to some drugs, might be so constructed as virtually to prohibit their sale. The omission of the words "pure and" removed this danger, but still left the difficulty as to what constituted an adulteration. This it was sought to meet by adding a clause containing a definition of "adulteration,"

which, especially as it is now qualified by the important word "fraudulently," introduced at the request of the deputation, will have the effect of considerably narrowing the range of interpretation that might have occurred had it been left to the individual opinion of judicial authorities. The following are the words of the new clause:—

"Any person who shall sell any article of food or drink or any drug, knowing the same to have been mixed with any other substance with intent *fraudulently* to increase its weight or bulk, and who shall not declare such admixture to any purchaser thereof before delivering the same, shall be deemed to have sold an adulterated article of food or drink or drug as the case may be, under this Act."

We are not surprised that a Government which lives upon the support of the shopkeeping class—the adulterators and vendors of adulterated articles—should be ready to emasculate a measure honestly framed for the suppression of adulteration. The amendment squeezed into the Bill by the Pharmaceutical Society will, however, prove one obstruction more to the effective operation of the measure, inasmuch as it will become necessary for the prosecutor not only to show that the article is adulterated, and that it has been sold as pure, but also that the adulteration has been effected with a fraudulent intention—an *inuendo* that it will be almost impossible to sustain.

The original definition of the crime legislated against was precise, simple, and comprehensive, and it is the only phrase which accurately expresses the object of the Bill.

Without doubt "every person who shall sell as pure and unadulterated an article which is adulterated and not pure," commits an act of roguery, and the word "fraudulently" is mere surplusage. As we have said, we expect no result from the make-believe of anti-adulteration legislation, which is gone through each year, but we are happy to believe that the public is being educated to see that a shopkeeper who sells wooden nutmegs for the price of genuine ones, and on the assurance that they are the real article, is a rogue and should be punished as such.

Notes on Current Topics.

Irish Medical Directory.

THE editor announces that as it is intended to re-compile and extend the greater part of the Directory, the circulars will be in the hands of the entire Medical profession in Ireland in a few days. The price of the Directory will be reduced to five shillings, with a further discount for cash payment.

Lunatics.

THE 26th Report of the Commissioners of Lunacy just issued, shows that the total number of lunatics, idiots, and persons of unsound mind in England and Wales, registered on the 1st of January last, was 58,640, being an increase of 1,885 upon the cases recorded on the 1st of January, 1871. These numbers do not include 170 lunatics so found by inquisition, and residing in charge of their committees, elsewhere than in asylums, hospitals, and licensed houses. The total of 58,640 is made up of 6,642 private patients, and 51,998 paupers; and the increase upon the year is represented by 188 of the former

and 1,697 of the latter. With the exception of 148 paupers in the Broadmoor Criminal Asylum, all the patients maintained in the various State asylums are placed in the private class, inasmuch as they are not chargeable to parishes, unions, counties, or boroughs.

Consumption—Its Treatment.

THIS subject has lately attracted renewed attention, and been the theme of articles in many Medical journals. The following from the *Cosmos* shows the direction of American thought:—

While the natural history of phthisis proves its spontaneous resolution by the unaided powers of nature alone, therapeutical experience demonstrates its curability by art. That this desirable result is not more frequently obtained is in consequence of its insidious character, the complex conditions of society and bad modes of living, with the reckless empiricism of resorting to any and everything promising relief, without the least regard to the true principles and practice which should govern the treatment of such a formidable disorder. Thus, from misapprehension of impending danger, neglect of, or inability to procure the means of relief, defective or bad treatment, and other causes, many are disabled or perish who otherwise might be saved by a timely and rational *methodus medendi*. Unfortunately, we can speak from some personal experience upon this subject, having been so seriously affected with hæmoptysis, expectoration of tuberculous matter—pustular, caseous, and calcareous, constant and chronic cough, dyspnoea, loss of appetite, great emaciation and debility, with frequent diarrhoea and other well known concomitants of this destructive malady, as to be declared by competent Medical authority twenty-two years ago to be a “hopeless case” of consumption, from which, however, we have recovered by a conservative course of hygienic and therapeutic measures. The curability of tubercular phthisis should therefore be more generally recognised, and more positive efforts be made for its successful treatment. The natural history of the disease shows that it tends to spontaneously resolve in two directions, viz., by softening and hardening of the tuberculous matter, through pustular, fatty, corneous, and calcareous degeneration, the latter being most conservative, as the former are apt to run into the more destructive forms of liquefaction connected with suppurative and colliquative disintegration generally of the plasma, tissues, and organs implicated. Hence the prominent indications in the treatment of phthisis *ab initio*, are to overcome the tendency to tuberculisation, prevent undue softening and destructive colliquation after its inception, and to promote hardening or the more conservative induration of the tuberculous substance, while at the same time allay all irritation resulting therefrom, obviate secondary disorders, and cause the removal of that already formed with as little disturbance of contiguous tissues as possible, in connection with the general efforts to hold in abeyance all exciting causes of the disorder, restore the healthy activity and harmony of every part and function of the body, and re-establish the normal integrity and tonicity of the entire organism. To meet these indications most fully requires all influences of a sanative character, both hygienic and therapeutic, especially good food, warm clothing, pure air, proper exercise of body and mind, sunlight, and an active out-door life rather than a sedentary and confined occupation. Indeed, plenty of fresh air and the invigorating influences included under the term of

climate with even a defective dietary, scanty clothing, and other privations, seem to be sufficient to quell and keep this disorder at bay, though the special peculiarities thereof which appear to be of most value are dryness and equability, for it is found that tubercular phthisis prevails most extensively in a damp and variable atmosphere, while it diminishes and disappears in a dry and equable climate, temperature being of less import, as both heat and cold are beneficial therein in connection with the preceding. Notable instances of this are presented in the arid plains of Africa and mountainous regions of South America. In our own country the same law prevails, as in Minnesota, Colorado, New Mexico, Florida, South Carolina, and other parts of the South and West. In the East some parts of New York, Pennsylvania, and New Jersey afford a favourable climate for the prevention and relief of this affection, especially those forms in which a very dry air is not required, as in the more purely nervous temperament, wherein it is apt to be too exciting. In parts of New Jersey for instance, during even the driest and hottest season, we have experienced prompt amelioration of this disorder with marked improvement in general health, while a change to the variable temperature and moisture of a neighbouring State was followed immediately by a return of the disturbance and debility. But usually climate is of little avail without proper nourishment. It is the privation of this which so often renders the most favoured climes a nullity, and so grievously disappoints the phthisical wanderers therein as well as those otherwise favourably situated, who either neglect or are unable to procure food suitable to the varying exigencies of this disorder. Hence it is all-important to secure a due supply of appropriate aliment in the form and condition, and at such times most acceptable to the invalid. With regard to the general character of this the teachings of physiology, pathology, and therapeutics point to the conclusion that the hydrocarbonaceous variety tends to the prevention and cure of tuberculosis, while an undue proportion of the nitrogenous promotes its inception and retards its resolution. In conjunction with these and other fundamental hygienic requirements, rational medication is of the greatest value to aid in obviating the abnormal tendencies and correcting morbid states. But as neither time nor space will admit at present of a discussion of the more purely medicinal agencies applicable in the different cases, stages, and complications of this affection, we will treat of them in detail as opportunity offers, our immediate object being to invite more particular attention to the general hygienic measures necessary to prevent and remove this dire disease, consumption.

“Arsenal de la Chirurgie Contemporaine.”

UNDER this title, the second volume of an important work has just been published by Messrs. Baillière & Co. The first volume, by Professor Gaujot, appeared in 1867; and the second, by Professor Spillmann, now completes the work. It is not a dry record of surgical instruments, but a practical and scientific treatise on the use of the latter, the illustrations being numerous and well executed.

To both civil and army surgeons such a work must prove simply invaluable, and so far as we are aware, there is not such a complete and practical work on the subject in any other than the French language. An English translation would no doubt command extensive patronage in this country and America.

German and French Watering-Places.

SOME talk has lately taken place about the several spas, and French practitioners are determined to discountenance all German resorts. They say France possesses everything she needs. The *Gazette des Eaux* has just published

a sort of list of errata for all books that mention German spas. It is as follows :—

Vesico-Vaginal Fistula.

DOCTEUR ROUBAIX (*Presse M. Belge*, July, 1872) mentions several cases of the above operation recently performed by himself. In one woman, *æt.* 35, the mother of eleven children, after the eighth labour, which was terminated by forceps, she felt that the urine passed by the vagina. She had three children since then. The fistula was simple, and seated one centimetre behind the neck of the bladder; measuring two centimetres transversely. After menstruation, on the 25th January, Dr. Roubaix proceeded to the operation on the 31st. With a tenotomy knife and a long-toothed forcep, the operator practised the paring of the fistula for the extent of a centimetre around the orifice. For suture he made use of Sim's needles with a double thread, for which he substituted a silver thread. Seven points of suture were thus placed without any incident, and the operation terminated in three-quarters of an hour. A sound of pewter was kept in the bladder and fastened to the hair of the vulva. Nothing particular occurred until the 9th February, when the points of

suture were removed. Patient left hospital cured on the 19th.

In the second case, a woman with vesico-vaginal fistula had been subjected to the actual cautery, and to cautery with nitrate of silver with no good effect; but still there remained a small fistula which would not close up. On the 21st February, Dr. Roubaix parod, by means of a tenotomy knife and a long-toothed forceps, the wall of the vagina in the extent of a centimetre around the fistula. Simpson's needles were used, and silver threads at once placed in six sutures from before backwards. The operation lasted an hour. Under the dry diet used in such cases the patient did well, and the sutures were removed on the 1st March, when union was found to be perfect.

In the third case, a girl, *æt.* 20, was delivered by forceps in hospital, and on the second day she remarked that the urine came through the vagina. On the 21st February it was found that the perineum had been split down as far as the rectum; but there was no incontinence of *feces*. On introducing Sim's speculum, there was seen in the bottom of the vagina, a little to the left of the middle line, a loss of substance measuring a centimetre and a half, obliquely directed to the right and upwards, through which the vesical mucous membrane tended to prolapse. Behind the fistula there was a *cul de sac*, but it was impossible to see the cervix uteri, as it had been completely destroyed. As the fistula was so far from the orifice, an assistant drew down the vaginal wall by a tenaculum; and bent tenotomy knives were employed to pare the mucous membrane of the fistula. The operation took an hour and a half, and succeeded.

Oculists and other Specialists.

WE recommend to our readers who desire to read Spanish an essay in *El Pabellon Medico*, June 28th, by Dr. Trill, in which the question of specialities is admirably treated in a leading article. According to Dr. Trill, the teaching of ophthalmology dates from the commencement of this century. A lady at the Court of Maria Teresa was obliged to betake herself to Paris, as there was no one who could operate on the eyes in Austria. A chair of ophthalmology was then created at Vienna. In 1813 the first clinical teaching took place at Vienna, under Dr. Beer. The revolution in France retarded the development of the study of ophthalmology, and it was only in 1830 that it began to be taught in France. In 1832 Sichel (père) gave some clinical instructions in the art. Desmarres, chef de clinique of Sichel, then established a dispensary. These are not attended much by Medical students, since they are not obligatory. In ancient Rome, there were numerous persons who adopted specialities: these were soon reduced in numbers; but the oculists remained. If the operation of cataract were distributed in equal parts among all Medical practitioners, each one would probably have to practice this difficult operation once in two years. Hence the advantages of specialities on this point.

Vaginismus.

THE operative procedure of Dr. Marion Sims in this affection, says the *All. Med. Central Zig.*, 1872, is scarcely ever made use of in Germany, on account of Scanzoni's earnest dissuasion. Dr. Scharlan mentions a case where all remedies ordered had been useless, and which was cured by Sim's operation. He therefore approves of the

operation in fit cases. Von Haselberg has seen in several severe cases of the disease very good results obtained by painting over the vulva and the clitoris with chloroform and oil of hyoscyamus, equal parts. Dr. Louis Mayer praises the operation of liquor hydrargyri nit. ox. Dr. Gusserow recommends painting with nitrate of silver, or tincture of iodine, when there is no symptom of inflammation.

Ovariectomy.

DR. E. MARTIN (*Berlin. Klin. Woch.*) says that in seven cases of ovariectomy performed by him in Berlin, with two deaths, he has come to the following conclusions:—

1. Whilst adhesions of the tumour with the front wall of the abdomen, and also with the epiploon, as also traces of any fresh peritonitis in the anterior surface of the abdomen, or coils of the intestine only make the prognosis bad in a certain degree, adhesions of the tumour with the walls of the pelvis, with the uterus and rectum, cause very grave complications, on which account the latter are a contra-indication to the operation. Indications of the existence of these are in the living patient, when the tumour passes deeply down into the foramen Douglasii, and is to be felt clearly through the vagina and rectum, inasmuch that movements impressed on the tumour from the abdomen do not cause a notable disturbance of the part of it felt through the vagina or rectum.
2. Previous puncture of the tumour through the abdominal walls, recommended by some, the author limits to those cases in which a palliative treatment is not possible in any other direction.
3. Great weight is to be laid on the careful cleansing of the abdominal and pelvic cavities by means of repeated new sponges, soaked in a lotion containing a little nitre, and also a little carbonate of potash. The sponges must be carefully cleansed by washing in hot water before being used. Before closing up of the wound in the abdomen, the other ovary ought to be inspected, and extirpated if it is cystic in its nature. The most successful treatment of the pedicle consists in grasping it in the pincette of Krassow and its division with a red-hot iron, which latter usually succeeds in effecting cessation of hæmorrhage. The closing of the wound in the abdomen takes place by means of short sutures and strips of plaster. After treatment consists locally in placing a piece of linen, dipped in carbolic acid lotion, on the wound, and over this warm water compresses: in cases of burning, pain, and tympanites, bladders of ice are used. The patient takes at first spoonfuls of cold water or iced water: In the first week she takes only fluid food. The opening of the bowels is only desirable in the second week. In obstinate vomiting some drops of laudanum upon a piece of ice are recommended. The sutures are not removed before the 5th day; and the pedicle comes away often not before the 11-14th day.

Efficacy of Iodine in the Incontinence of Urine in the Aged.

In the *Independente* of July 5th it is said that Dr. Schmidt has obtained the best results from iodine in palsy of the bladder. In a woman of seventy-five years old, who had suffered for four years from incontinence of urine and involuntary dribbling, she was able after only twenty-four hours to retain the urine, by taking one drop of tincture of iodine every hour. She continued the medicine

for fifteen days (one drop every two hours), and the success remained complete. The medicine was then left off and the incontinence reappeared. She recommenced with it, and the incontinence entirely disappeared for two years until her death. In an old man of over seventy, who suffered for six months from the same disease, he obtained progressive amelioration and radical cure by using pills, each of which contained 50 milligrammes of tincture of iodine.

THE Public Health Bill passed the third reading in the House of Commons on Friday.

MR. TEEVAN has been elected a corresponding Fellow of the Medical Society of Odessa.

LORD JERVISWOODE has decided that firms, as well as individuals, are entitled to vote in the General Court of Contributors to the Edinburgh Infirmary.

At the recent distribution of prizes at University College, London, the greatest number were gained by Dairoki Kikuchi, a Japanese.

PRINCE BISMARCK has ordered rigorous precautions to be taken in all the Pomeranian ports against the importation of cholera. Two cases of cholera are reported in Berlin, Unter-den-Linden having been attacked, but it has not been finally ascertained if it is the true Asiatic epidemic.

THE Profession will participate in the unfeigned gratification with which we announce that Dr. Rawdon Macnamara, of Dublin, is almost completely restored to his accustomed health, and is again actively engaged in the practice of his profession.

THE annual meeting of the Medico-Psychological Association held, as we have announced, on Wednesday, at Edinburgh, under the presidency of Sir James Cox, the Senior Commissioner in Lunacy for Scotland, was an unusually successful one. The Association decided that their next place of meeting should be London, and elected Dr. Harrington Tuke as president for that year. We have no doubt he will worthily bear the honour that thus comes to him.

WE take the following from the *Boston Medical and Surgical Journal*:—

LEARNED V. VULGAR CREDULITY.—A QUERY.—“In the seventeenth and eighteenth centuries it was a very common belief, and accepted on the most slender evidence, that there were poisons in use so subtle that they might be conveyed in a letter, which would prove fatal to the reader, or (might be) inhaled in the fragrance of a bouquet. We might to some extent credit these accounts if we had grounds for supposing that the poisoners of old were skilful enough to isolate the zymotic poisons—the only poisons we know which can be carried in such a way.”

We would like, in all seriousness, to ask Prof. Ferrier, from whose very learned lecture on Forensic Medicine at King's College last May, we take the above extract, on what “evidence” he affirms that we “know” that there are “zymotic poisons”; and, more especially, on what more than “the most slender evidence” do we know that

such poisons, if there be such, "can be carried in a letter which would prove fatal to the reader, or can be inhaled in the fragrance of a bouquet?" Has not the term *zymotic* up to the present time been merely a learned expression to cover ignorance? Mr. Simon, an undoubted authority, "scouts the notion of any true fermentation," says Dr. Watson in his last edition; adding that Liebig could only have meant "analogically, just as we all speak now-a-days, of zymotic diseases."

What can be expected of poor "ignorants" if learned professors with their superior knowledge and wisdom show such credulity in their very teachings from the college desk?

We pause for a reply.

THE BRITISH ASSOCIATION.

As already announced in our columns, this year's meeting of the British Association for the Advancement of Science will be held at Brighton. The meeting will commence next Wednesday, August 14, and continue till Thursday, August 22, when it will close with the usual excursions for members and associates. The President-Elect is a member of our Profession, Dr. W. B. Carpenter, F.R.S., &c., who will deliver his inaugural address on the evening of the 14th. On Thursday evening, the 15th, and on Tuesday evening, the 20th, *soirées* will be held. The entire northern block of the Pavilion property is allotted to these, namely, the Dome Assembly Room, the adjoining large building used in the days of the Regent as the Royal riding school, but now converted into a corn-exchange, and the recently-built free library and museum. The exhibition of pictures, articles of vertu, philosophical instruments, and objects of artistic and scientific interest, will be very large and varied. The Brighton Natural History Society are arranging a complete flora of the south coast, both living and dried specimens; also a microscopical display, to which the most eminent London makers and the leading metropolitan societies will contribute, and which cannot but be attractive. It is anticipated that about 400 microscopes will be in use during each *soirée*. On Friday evening, the 16th, and Monday evening, the 19th, lectures will be delivered by leading scientific men. The various sections will sit daily. An announcement has been made by the *Athenæum* that whatever information is received from Dr. Livingstone will be communicated at this Brighton meeting of the association, and few things can be more interesting than news of this renowned and intrepid Medical missionary. The Town-hall room, designated for the Geographical Section, will hold some 900 people; but it has been suggested that the Livingstone communications should be read in the Dome Assembly Room, which will seat from 2,500 to 3,000 persons. Four half-day excursions are arranged for Saturday, August 17, and five for Thursday, August 22. In connection with these several county noblemen and gentlemen will display liberal hospitality. The new Brighton Aquarium will be opened and stocked for the meeting of the association. Many invitations have been sent through the Mayor of Brighton, Mr. Cordy Burrows, another member of our Profession, to Continental and American *savans*, who will attend the meeting as the guests of the municipality. Numerous acceptances have already been received. Working men delegates are also invited from London and the chief centres of industry and manufactures, and a special lecture for working men will be delivered by Mr. W. Spottiswoode, F.R.S. As to the railway arrangements, return tickets will be issued by the Brighton Company to members of the association, available to travel by any train between London and Brighton for the term. The railway company will also allow these fortnightly and monthly tickets to be issued to members of other scientific bodies in London on production of proof of membership. This is of the greatest importance to the Profession, as the members of our Medical societies will

thus have the opportunity of attending on the best terms. We beg to suggest that these societies should save their members trouble by preparing a certificate of membership for those who wish. We presume the company would also accept the diplomas of either of the Royal Colleges of Physicians or Surgeons. Applications for association tickets and local information should be addressed to the Rev. J. Beck, secretary of the Local Executive Committee, at the Royal Pavilion, Brighton. We heartily wish the great scientific congress of the year may be one of the most brilliant.

Literature.

HEALTH AND COMFORT IN HOUSE-BUILDING, OR VENTILATION WITH WARM AIR BY SELF- ACTING SUCTION POWER (a).

THIS is a very important contribution to the difficult subject of warmth and ventilation of private or public houses. It is the contribution of two Medical men to a knowledge of the vexed question of how to combine warmth and purity of air in our houses. All who know how the attempt has failed in the construction of some recent French Hospitals, such as the Lariboisière and others, will be interested in reading this clear and very precise treatise.

To procure a sufficient supply of fresh air in houses may, at first sight, appear a very simple and easy matter, but in the first place, there must be two openings, an inlet and an outlet. MacKinnell and others think that this is all that is required; but it must be remembered that the outer air is cold air, which in winter cannot be admitted freely without danger, so that although it is not difficult to warm a house or to ventilate it, it is a very difficult problem how to do both. Houses should be built for winter necessities in our climate. Captain Galton, of the Royal Engineers, has advised that the smoke flue be surrounded by a fresh air flue, the contents of which are discharged at the upper part of the apartment. The air of the room may thus be changed more than thrice in an hour. This plan is only applicable to single rooms; but our authors say that "no plan of ventilation by fire-suction applicable only to single rooms can possibly supersede the necessity of a general plan for the whole house." The kitchen fire is the only one in the house that is kept in throughout the year. "A general plan that includes the whole house is then absolutely necessary, and this, of course, involves the maintenance of an agreeable warmth in all the central thoroughfares and passages, in order that the air which enters the rooms from them may be warm."

Unless a certain portion of the daily life of all persons, especially children, is passed in the open air, the health will surely deteriorate. But we must not fall into the error of supposing that a badly ventilated and draughty house escapes any of the evils of indoor life; on the contrary, whilst destitute of the former it possesses the latter in an aggravated degree. "We do not hesitate to say that a properly warmed and ventilated house is of the very greatest consequence to health and comfort, and in many cases to life itself."

Reference is made by the authors to the present change in the views of physicians relating to the causation of pulmonary consumption: many cases are said to be nothing more than the result of inflammation in the chest, imperfectly cured, or continually renewed by fresh cold brought on, doubtless often by imprudent exposure out of doors.

(a) "Health and Comfort in House Building, or Ventilation with Warm Air by Self-acting Suction Power." By John Drysdale, M.D., and J. W. Hayward, M.D. Lond. E. and F. Spon, Charing Cross. 1872. Pp. 113, with five plans.

The making an opening at the top of a room is not sufficient for ventilation, because air must enter as well as go out. To prevent waste of heat, care should be taken in the original plan of a house to have a central hall, corridor, lobby, fresh-air chamber, or vestibule, separate from the stairs lobby, and into which no outer door should open. A double entrance to the front vestibule is necessary. Rooms may be warmed by Stephen's fire-stoves. The authors are no advocates for warming the house by means of heated air; all they recommend is, that the incoming air which is necessary for ventilation should be heated to about 65° Fah., which is best done by passing it through or over coils of hot-water pipes. In one of the houses mentioned in this work the air is warmed by hot water on the low-pressure system with large pipes. The cost of this warming must not be considered an extra expense, for it is theoretically saved in the smaller fires necessary for the rooms. The opening into the house may be in the basement, and the position for the hot-water pipes is the basement of the central hall.

There is an inlet into each room near the top of each room through the cornice by numerous small openings. The air is let into the room at 65°, and if ventilation is required there are either persons in the room or a fire, which causes the foul air to be heavier than that which enters. The windows are made close-fitting, or are hermetically sealed in such a system. The vitiated air has outlets at the ceiling over the gas leading by a flue to the foul-air chamber at the top of the house. The suction power described by our authors is always acting. The up-cast foul air flue is separated from the back of the kitchen fire by a sufficient thickness of brickwork, and the kitchen chimney is made of considerable length and contracted at the top by means of a chimney-pot fit for the purpose. If this be not sufficient to give enough draught, a few coils of Perkin's inch-bore water-pipes are recommended to be placed within the up-cast shaft. The air from the house passes through a foul-air chamber in back of the house by means of a shaft down to the back of the fire-grate in the kitchen.

By the combined use of such means the authors assure us that they have attained the desiderata of a healthy and comfortable house—viz., an abundant supply of sufficiently warmed fresh air, and a continual process of removal of the vitiated air.

In Chapter II., a detailed description is given of two houses in Liverpool built according to the principles spoken of in the preceding chapter. One is a villa at the sea-side belonging to Dr. J. Drysdale, the other a town house, the residence of Dr. Hayward. In Chapter III. there are some suggestions given with regard to the materials to be used for house-building which are very practical. The Appendix gives the result of thermometric experiments made at the town residence of Dr. Hayward, and narrates the velocity of the ventilating current observed at various points in its course in that house by several gentlemen posted in various parts of the house before and after the lighting of the fire in the kitchen.

This is a very important contribution to the subject of ventilation and warmth, and shows how necessary it is that such subjects should be investigated by physiologists and not only by engineers. We are much mistaken if builders and architects do not find this treatise of immense importance, and to all such and to the practical physician and student of hygiene we most confidently recommend the perusal of this acute and most ably-written work on ventilation and warmth.

THE CONTAGIOUS DISEASES ACTS (a).

THE author of this pamphlet of thirty-eight pages is in favour of the Acts of 1866-69, and quotes a good deal of

(a) "The Contagious Diseases Acts and the Contagious Diseases Prevention Bill." By Anthonos. Beshaw. 1872.

evidence *pro* and *contra*. But the subject is so full of thorns that we are reluctantly obliged to leave it for a future epoch, when men and women are more able to discourse about such topics without squabbling.

VACCINATION AND THE VACCINATION LAWS (a).

THIS is a trashy production written, of course, by a clergyman. We really do wish that some change would take place in the studies of our clergy, whether in or out of the Establishment. Would it be too much to ask that they should pay some little attention to science as well as theology, or at any rate until they do remember the dictum *ne sutor ultra crepidam*, and abstain from writing about what they do not understand?

Correspondence.

ON THE EXPANSIONS AND CONTRACTIONS OF THE BRAIN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—When attending hospital in a case of compound fracture of the skull with displacement of bone, I noticed with very great interest the alternate heaving and subsiding of the cerebral mass, which phenomenon was thus deeply impressed on my mind. Since that time in the practise of my Profession observations have occasionally helped to confirm me in the view, that this cerebral motion is an independent motion. I have lately been attending a child which during teething had fits and many other symptoms of a disturbed brain. Sometimes with this child the breathing would become very rapid (40 per minute), yet the child would go to sleep as usual; and without any special treatment the rapidity of breathing would in a day or two cease. Nerve substance appears to move muscular fibre, and nerve substance is seen in the brain to be itself in motion. Hence, it seems natural to suppose that that which moves another should have in itself a power of motion. Believing, therefore, that the alternate expansions and contractions of the brain, which are synchronous with respiration, are the moving powers which cause the respiratory movement, I am anxious to know what are the physiological facts or arguments which uphold the contrary conclusion, viz., that respiration causes the alternate heaving and subsiding of the cerebral mass, and I shall be glad if any of your readers can correct my views.

I am, Sir,

Yours obediently and obliged,

DUNCAN R. McNAB, M.R.C.S.

pping, August 1872.

Legal Intelligence.

SUMMER ASSIZES, GUILDFORD,

JULY 31ST, 1872.

(Before Mr. Baron MARTIN and a Special Jury.)

MAUNDER v. WAKLEY.

THIS was an action by a Medical gentleman against the proprietors of *The Lancet* for libel. The case appeared to excite great interest in the Medical Profession, and a large body of the members of that Profession were present in court.

The plaintiff is one of the surgeons of the London Hospital, and had criticised an operation by another surgeon

(a) "Vaccination and the Vaccination Laws, a Physical Curse and a Class Tyranny." By Rev. H. Rothery. Manchester. 1872.

there; on which a controversy had arisen, in the course of which *The Lancet* published an article commenting on Mr. Maunder's conduct as unprofessional.

Mr. Hawkins, Q.C., Mr. Day, Q.C., and Mr. T. Salter, were for the plaintiff; Mr. Serjeant Parry, Sir George Honyman, and Mr. A. L. Smith were for the defendants; Mr. Kenelm Digby watched the case on the part of the Committee of the London Hospital.

When the cause was called on, a conference was held between the counsel and the parties on both sides, which lasted half an hour. In the result,

Mr. Hawkins stated that they had come to an arrangement which would obviate the necessity for a trial of the case. His client, Mr. Maunder, he said, had brought the action to vindicate his honour and character as a member of the Medical Profession, and as one of the surgeons of a great public institution. That object, however, would be abundantly attained by the course which was about to be taken. There was a right, no doubt, to discuss any topic of public or professional interest, so that improper motives were not imputed and no improper imputations were made upon character. Any imputations upon his client's character would be fully withdrawn, and that being so, he would be satisfied with a verdict for 40s. and the payment of costs, which would be an indemnity to him for the expense of this action.

Mr. Serjeant Parry said he appeared for the Messrs. Wakley, the proprietors and editor of *The Lancet*, who had felt it impossible to pass over in silence the controversy which the plaintiff had raised, and which was certainly a matter of interest to the Profession; but they had no intention of making any imputation upon the character of Mr. Maunder, who himself had been a contributor to *The Lancet*. They, therefore, had no hesitation in withdrawing any imputations, and, indeed, in declaring that none were intended, and they assented to the course proposed to be taken.

The learned Judge intimated that he quite approved the course suggested. He observed that he believed the parties had supposed that in this action for libel the original matter of controversy could be gone into, but that was an entire mistake, and he should have allowed nothing to be gone into in this action but the libel and the libel alone.

The verdict was then entered for the plaintiff for 40s.—*The Times*.

Obituary.

THE LATE DR. ALDIS.

We announced last week the untimely demise of this gentleman. We cannot do better than cite, as a proof of the estimation in which he was held, the following resolution. At a special meeting of the monthly committee of the Surrey Dispensary, held at the Dispensary, Great Dover Street, Southwark, on Tuesday, the 30th day of July, 1872, Henry Palmer, Esq., in the Chair, it was moved by Mr. Millman, seconded by Mr. Rockley, and resolved unanimously—

“That this Committee desire to offer their most sincere and heartfelt condolences and sympathy with Mrs. Aldis and her family in the great affliction they have sustained by the recent decease of the deeply lamented Charles James Berridge Aldis, Esq., M.D., the Senior Physician to this Institution, and at the same time to express their acknowledgment of the irreparable loss the Charity will sustain by the death of so valuable and efficient an officer, admired and respected by his fellow-workers for the conscientious, upright, and able manner in which for so many years he discharged the arduous and trying duties of his office, and beloved by the poor for the uniform kindness and attention he at all times paid to the patients under his care.”

Thus it is seen that a committee he had long served with fidelity appreciates his worth.

To this we will add an extract from the *Birmingham Daily Gazette*, which gives some interesting particulars of him:—

“The death is announced of an eminent Medical man, one of the old school, who, together with the gentlemanly traditions and Conservative tendencies of former days, was a

practical Reformer. Dr. C. J. B. Aldis, the most efficient and painstaking of the officers of health, whose name is familiar to all readers of the daily papers for his voluminous and useful reports as to the sanitary condition of St. George's, Hanover Square, was the son of Sir Charles Aldis, also a Medical man. He devoted his whole life, not merely to the active duties of his Profession (in which, besides being a member of the Council of the College of Physicians, he held appointments which filled nearly half a column of Medical directories), but was associated in early life with the Earl of Shaftesbury in ameliorating the condition of the dwellings of the poor in the worst parts of Westminster. He took great interest in the question of workhouse reform, but his memory will probably be most fondly cherished by those who benefited by the act, passed mainly through his influence, to prevent the overworking of dressmakers' and milliners' apprentices. The act was never efficiently carried out by other officers of health, as it was a troublesome and unremunerative duty; but in his own district woe betide the fashionable milliner or dressmaker who ill-treated an apprentice or worked her beyond the legal hours. The best testimonial to the memory of this good man would be some really efficient measure for the protection of overworked seamstresses. Dr. Aldis took a large share in the foundation of the St. Paul and St. Barnabas Dispensary, in Ebury Street, of which he was the honorary physician since its establishment some fourteen or fifteen years ago, and his unceasing labours as Medical officer of health for the large parish of St. George, Hanover Square, no doubt brought on his premature death. For some time he had been ailing, but he died in harness, the extreme heat of the weather last week and his testing some gas in the very midst of it, being no doubt the immediate cause of his decease. On Thursday evening he had been at the council of the College of Physicians, and when he came home he said to his family that he wished he had stayed to dinner, as he felt so much better, but no doubt the prudent course was best. On Friday he went to his hospital, and after luncheon, as usual, dozed in his chair, when, his wife coming in, she found he had passed away without any pain. Dr. Aldis was educated at St. Paul's School and at Trinity College, Cambridge, and took the degrees of M.A. and M.D. He continued throughout life to take the greatest interest in his old school and university, regretting that comparatively few of his profession did so. He rarely missed the Speech-day at St. Paul's, and was not only on the committee of nearly every Conservative candidate for the University of Cambridge, but took an active part in all university matters, so far as a busy non-resident could do. Dr. Aldis was delighted at the return of Mr. W. H. Smith for Westminster, and the last public affairs in which he was interested were the sanitary commission of which Sir Charles Adderley was chairman, and the election of Viscount Mahon for the School Board. He has left a widow and one son (who, singularly enough, on the day of his death was coming home with the joyful news of an unexpected appointment of £1,500 a year in India) and two daughters, one of whom is married to Mr. Turner, a Norfolk rector, and the other, who was her father's righthand in preparing his reports, is single.”

Another citation will conclude our obituary:—At a meeting of the St. George's (Hanover Square) Vestry, the Rev. H. Howarth, B.D., the rector, moved—“That this Vestry desire to record their sense of the great loss this parish has sustained by the death of their esteemed Medical officer. To his eminent qualities as a physician were added scientific talents of a high order, the whole of which were brought to bear upon the important interests entrusted to his charge with a conscientious zeal and faithful diligence that cannot be too highly appreciated. That this resolution be communicated to Mrs. Aldis and the family, with the assurance that the Vestry sympathise with them most sincerely in their present position.”

Medical News.

Bequests, &c., to Medical Charities.—The Grocers' Company have given £500 to the London Hospital. The Leeds Public Dispensary has received £200 from the representatives of the late Miss Philippa Hamilton, of Harrogate. Miss Louisa Yea bequeathed £200 to the Taunton and Somerset Hospital.

Royal Medical and Chirurgical Society.—By order of the Council, the library will be closed from August 12th to September 12th, both days inclusive.

The British Medical Benevolent Fund.—At the monthly meeting, held last week, the committee considered twenty-two applications for relief, and among thirteen of these the sum of £115 was distributed in grants of £5 or £10. Donations were reported of £31 10s. from the Merchant Taylors' Company, and of £52 10s. from the Drapers' Company; also a new annual subscription of £20 from Sir Richard Wallace.

The International Ophthalmological Congress.—A preliminary meeting of the members of the Congress took place at the Royal College of Physicians of London on Wednesday evening last. The time was chiefly occupied in the transaction of formal business. Among the foreign visitors were Prof. Donders, Drs. Warlomont, Galezowski, de Wecker, Delgado, Meyer, Noyes, Green, Joy Jeffries, Jugo, Horner, Zehender; and nearly all the London and many of the provincial ophthalmic surgeons were present. On Thursday morning the members assembled at eleven o'clock, and Mr. Critchett, the Chairman of the Executive Committee, welcomed them to England in the names of himself and of the other ophthalmic surgeons of London. Professor Donders was then elected as President of the Congress; Dr. Williams, of Boston, U.S., and Dr. Warlomont, of Brussels, as Vice-presidents; Dr. Zehender, of Berne, and Messrs. Soelberg Wells and Hulke as Secretaries. The scientific business was then commenced, and continued up to Saturday night.

Society for Relief of Widows and Orphans of Medical Men. Founded 1788. Incorporated 1864.—The Quarterly Court of Directors of the Society was held July 10th at 53 Berners Street. The chair was taken by Charles Hawkins, Esq., V.P. Fifty-eight widows and forty children made applications for grants, and the sum of £1,312 10s. was distributed amongst them, the amounts varying according to the wants of the respective applicants. Five widows were added to the list of annuitants. A donation of £100 was announced by the acting treasurer, James G. Ware, Esq., as having been received from Dr. Hare, to whom a vote of thanks was unanimously passed. The directors again appeal to their professional brethren for assistance to enable them to meet the increasing demands on the funds of the society.

Royal College of Surgeons in Ireland.—At the Quarterly Examination held on the 9th, 10th, 11th, 12th, and 13th of July, the following gentlemen passed the first half of their examination for Letters Testimonial of the College, viz.:—James H. Allen, William Charters, James Creagh, Anneley, C. C. De Renzy, Patrick C. Devany, George H. Dundas, Arthur B. Finney, William A. Fitzgerald, John Going, Patrick A. Hayes, Michael Healy, Christopher J. J. Hughes, William Irvine, Francis B. Kane, Kingston, D. L. Kirkwood, Henry Longford, Michael Loughman, Richard H. Lyon, Charles M'Clintock, John Creary, Henry G. Murray, George Rogers, Patrick A. Shannon, Patrick J. Slevin, Charles C. Smith, George L. B. Stoney, Auster F. Walker, Wm. Walter, Thomas I. D. C. Williams, and Joseph Wybrants. At the preliminary examination held on the 17th July, the following candidates were adjudged certificates of qualification. The names in the first and second classes are arranged in order of merit. *First Class.*—John Cristal. *Second Class.*—Wm. Folliot, Abraham W. Browne, Edwin Young, James Mathews, George Brown, Michael Fitzgerald, and Louis E. Delmege. *Unclassed.*—Andrew F. Adams, Arthur Barron, W. A. Bonyng, John J. F. Cassidy, John Crean, John Emerson, Richard J. Hassard, Samuel Keays, Edward E. Lennon, George Lyndon, Henry M'Carthy, John P. Nicolls, George Stoker, and Daniel N. Wallace. At the quarterly examination held on the 23rd, 24th, 25th, and 26th of July, the following gentlemen passed their second, third, and final examinations for the Letters Testimonial, and were admitted licentiate of the College, viz.:—James H. Allen, John Barton, John H. Borwell, Andrew J. Brady, David J. Carleton, Michael J. Clune, Robert N. Denning, Rowland J. Denny, Charles J. Diamond, William C. Downing, Robert J. Eyre, Thomas Fenton, William A. Fitzgerald, Robert H. Foot, Nicholas French, James N. Frood, Raptist Gamble, Thomas Griffin, Patrick A. Hayes, George C. Jackson, Robert G. Johnstone, Wilmot J. Jones, Francis B. Kane, Robert G. Loverock, Michael J. Malone, Brownlow R. Martin, James M'Gann, Archibald M'Kinlay, Joseph P. M'Sweeney, Robert J. Miller, Patrick Mulcahy, Edward R.

Mulock, James W. Murtagh, Joseph J. Nolan, Edwin Page, James R. Panter, Gabriel O'C. Redmond, Robert Sproule, John R. H. Sutton, James C. Weld, Thomas A. Woods, and Frederick E. Young.

The Cholera in Russia.—According to the last accounts from Kieff, says the *Eastern Budget*, the cholera has almost entirely disappeared from that city. Even in the monastery (Iarra) of Kievo-Petchersky, which was the principal centre of the epidemic owing to the great number of pilgrims who assembled there, the number of new cases has become quite insignificant. The total number of persons who died of cholera during the short period of the prevalence of the epidemic at Kieff was 1,300, or nearly one half of the total number of sick in the city. At St. Petersburg, according to the *Police Gazette*, the number of deaths from cholera on the 19th inst., was 23. Since the disease broke out in the capital (on the 23rd of June) the number of patients was 896, of cures 133, and of deaths 367. There have also been 262 deaths from small-pox since the 13th of April.

Gleanings.

Biliary Calculi.

DR. J. C. VAN WYCK reports F. T., æt. 59, female—a case which he treated at intervals, for the space of five years. Prof. N. R. Smith, of Baltimore, had observed the case twenty-five years previously, at which time, although she was residing in a malarious district, she speedily recovered her usual health. Shortly before Dr. Van Wyck was called in attendance she had suffered greatly from "bilious attacks," and had become reduced from corpulency to a condition of extreme emaciation. These attacks were of irregular occurrence, varying from ten to sixty days. The general health was not very good, appetite irregular, bowels constipated, and, owing to a constant dread of a return of the trouble, together with family afflictions, she became very despondent and depressed. The attacks would be instantaneous; with no previous warning she would be seized with vomiting, intense pain over the liver, and complete jaundice occurring within half an hour from the time of seizure. The jaundice hue differed from any previously seen, being the tint of a not fully ripe lemon, and the skin presented a shining appearance, in lieu of the usual flat, dead colour of icterus. The paroxysm would last from one to two hours, with intense, uninterrupted suffering. The application of mustard to abdomen and feet, Ac. hydrocyanic to quiet stomach, and morphine to allay pain, would generally control the attack, and, after a mercurial purge on recovery, she would be as well as ever. During the intervals every remedy that could be suggested by different Medical men called in consultation, and who all diagnosed as above, was tried, sometimes with apparent prospect of permanent relief, but all eventually failed, and the attacks now after one year, increased in frequency until for the space of three weeks, forty-eight hours rarely elapsed without a severe one, and the patient rapidly failed, when Dr. Van Wyck determined to try the effects of strychnine, which was accordingly given in doses of 1-50th of a grain every three hours. The beneficial effect was so immediate that all other medicine was discarded, and the strength supported by it and easily assimilated articles of food. In three weeks the patient left her room; the bowels acted freely; and the general improvement was so marked that the medicine was increased to 1-10th grain daily.

The patient faithfully persisted in the use of strychnine for six months, increasing the quantity to 1-5th grain daily, when believing herself free and cured, she abandoned its use, to be seized again in three weeks with another familiar attack, which necessitated the continuance of the remedy. Within the next two years she passed from the observation of Dr. V., but he learned that while away from home she had again left off the only remedy that had ever been of the slightest service to her, and, in a paroxysm of the well-known attack, had died. There was no autopsy made. The question that naturally arose in the mind of Dr. Van Wyck was, was this a case of biliary calculi, or a spasmodic action of the hepatic duct, causing a distension of all its ramifications, and cutting off the flow of bile?

Long before the patient had passed from his observation,

the Doctor had taken the latter view, for the reason that with every attack, gall stones had been diligently sought for and never found; and this gall bladder could not be detected on examination after these innumerable attacks, as would have been the case were it distended with calculi sufficient in quantity to account for the frequency of the seizures. Again, spasm of the duct is frequently followed by instant jaundice, as in the present instance, while Villeneuve, and other eminent authorities, teach that slow, depressing passions of the mind are fruitful causes of producing spasm of the duct.

Dr. Van Wyck added that, during the past three years, he had visited another female, æt. 41, whose case he diagnosed as biliary calculi. It resembled the first one reported; in fact, the only difference being that the resultant jaundice was not observed until several hours after the seizure, and its hue was the typical icteric one. The treatment has been—hydrocyanic acid to allay nausea, morphine hypodermically, and a pill of podoph. assafœt. and nux vom. Owing to the infrequency of the attacks, the constant use of the nux vom. was considered unnecessary. There had been no attack for eight months.

Dr. Thos. Buckler, of Baltimore, published an article in the *Half Yearly Abstract*, July, 1868, on this subject. He gave chloroform in teaspoonful doses every hour during the attack, and one dose after each meal, for five subsequent days; he then used hyd. succinat. ferri per ox ʒjss, aquæ. ʒvjss. M. S. ʒj., after each meal; this was continued for three months with benefit. Three other cases submitted to the chloroform treatment were promptly relieved.—*St. Louis Med. Journal*.

We believe we are not premature in the statement that the filling of the vacancy in the Medical Staff of the City of Dublin Hospital caused by the resignation of Dr. Hargrave has been practically decided upon, and that Dr. William Ireland Wheeler will succeed to the surgery of the hospital.

The Admiralty having decided to establish in the Navy a personal record of the Medical history of every petty officer, seaman, marine, and boy in the Service, have issued the necessary instructions accordingly. The *United Service Gazette* says that on board ships carrying Medical officers, the Medical officer in charge is to keep the Medical history sheets, and where there is no Medical officer, the duty is to be performed by the Officer in Command.

THERAPEUTICS :

An Address delivered at the Annual Meeting of the Norfolk (Massachusetts) District Medical Society, May 8, 1872.

By B. E. COTTING, M.D. Harv.

(From the *Boston Medical and Surgical Journal*, July 4.)

MY FIRST QUESTION

As a Medical Student,—

ITS SOLUTION A SURE BASIS FOR RATIONAL THERAPEUTICS (a).

TWENTY years ago, on the unexpected failure of the appointed speaker, at the solicitation of the officers of this Society, I prepared the paper (b) which was read at the annual meeting. That service was performed in early acknowledgment of the duty incumbent on each member to contribute his allotted share for the advancement of the Society and our common profession. In continued recognition of the same duty I return to note a few of the changes in the interval, and to indicate, in one direction at least, the difficult task we must leave unfinished to our successors.

The Address of 1852 urged the necessity of solving *The First Question* I asked my teacher when, for the first time, I

(a) I prefer to be called a fool for asking the question, rather than to remain in ignorance.—Dr. JOHN HOMANS (while a Medical student, 1800) to an upbraiding Professor.

(b) Entitled *NATURE IN DISEASE*; published in the *Boston Medical and Surgical Journal*, October 13, 1852.

was taken as a medical student into the presence of a sick man;—*what will be the course and result of the disease if left to itself, without medicine?* This question my teacher, than whom never existed a more observant or conscientious practitioner, honestly and frankly confessed that he could not answer; such a case had never to his knowledge been left to itself. The reply rather surprised the young beginner; for then, as now, it seemed a most befitting question to ask, and one that should be answered before any rational administration of drugs should be determined on. Elsewhere an answer was sought for, but in vain. The books did not give the desired information. All the cases they furnished had been submitted to remedial agents of real or supposed efficacy. The question appeared never to have been thought of; or, if thought of, not to have been deemed worthy of solution, or even of consideration. Nevertheless, it seemed not an unreasonable question; and the resolution was tacitly formed to seek opportunities to solve it, so far as practicable, if only for myself. Some of the results of observations made for that purpose were cited in the paper read to this Society. It had been proved, even at that time, to my own satisfaction at least, that some of the gravest or most painful diseases, left without drugs, but otherwise properly cared for, will go on quite as favourably, and with—as many recoveries, as when submitted to customary medication, and much better than when violently, or as the word then was, *heroically* treated.

Although the Address did not contain any suggestion inconsistent with the firmest faith in the efficacy and usefulness of medicines when properly tested, or in the incalculable good to the sick to be derived from the attendance and care of the educated and scientific physician, yet human diseases had been treated so invariably with drugs, and every recovery had been so universally attributed, by the public and the Profession, to the efficacy of the particular drug administered, that no sooner was the statement promulgated that unaided Nature (c) was adequate to the cure of diseases in a large proportion of cases, than there arose the cry of “heresy.” But this cry was also raised, about that time, in regard to some of the foremost men in the Profession, who apparently were not very much deterred thereby from proclaiming their convictions to their associates.

New suggestions are seldom received at once without hesitation. Often, at first, they meet with much opposition, though destined, soon after it may be, to be fully accepted. Thus, five years later, in 1857, when Sir James Forbes (*Nature and Art in the Cure of Disease*) urged with great earnestness a zealous study of the Natural History of Diseases, averring that, “on the profounder, more critical, and purer study of *Nature* as manifested in *Disease* rest, in my judgment, the best hopes of improvement in the Medical Art,” he was constrained to admit that, “the finding of a proper field for such observation and study is by no means so easy a task as might, at first sight, appear,” and to declare it to be a lamentable defect that there was “no distinct chair for instruction in the Natural History of Disease” in any of the Medical Schools. Labouring hard to establish these positions, and feeling, he said, that they were at variance with those of most Medical men, the best informed as well as ordinary practitioners, he showed that all along the ages there were numbers of cases so absurdly or so inertly treated that they must have recovered through Nature alone, though the credit of the recovery had uniformly been given to Art. And, on such inadequate cases as these, he was content, as it were in a spirit of compromise, to rest an elaborate plea for a mode of treatment of disease that might “occupy the happy medium between doing too little, and doing too much,”—between, on the one hand, the fashion of mystified trifling then coming into vogue, and, on the other, the not less objectionable perturbative measures so often resorted to. On such unstable foundations, and without ascertaining for himself in a single instance what Nature of itself could do, he proposed a method of treatment which, after the manner of the times, he maintained in its result “must be accepted as superior to that which unassisted Nature can supply.”

(To be continued.)

(c) Nature, “with a capital N,” by which is meant, not a “vague external secondary personification,” nor a “metaphorical subcutaneous female entity,” but the forces and laws of the Universe (to make the statement broad enough) so far as concerned in disease, its existence in the world, its inception in individuals, its progress, culmination, decline, and departure (uninfluenced by human interference); and always presupposing an Originator, Law-giver, or, if any one prefers term, “Great Artificer.”

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this request.

All communications intended for insertion, must bear the name and address of the writer; not necessarily for publication, but as a voucher of good faith.

Rejected MS. will always be returned, if a request be received from the author, within one week after the article or letter has been declined.

SUBSCRIPTIONS IN THE UNITED STATES.—A Correspondent has drawn our attention to the fact, that some of the houses in the United States are charging the enormous figure of 15 dollars per annum (more than £3) for supplying this Journal to different parts of the States. We beg, therefore, to state that we shall be happy to supply the same regularly post free per annum, if paid in advance, for considerably less than half this amount, viz., six and-a-half dollars (about £1.6s. 0d.), either direct from our offices in this country, or through our recognised agents in the United States.

TO OUR SUBSCRIBERS.—It having been suggested to us that it would be a matter of great convenience to Subscribers visiting the metropolis to know where they can give instructions for their letters to be addressed previous to leaving home, we have pleasure in informing them that the Publisher has consented to take charge of letters addressed to his care, and that he will place a desk at the disposal of Subscribers whose names are upon our lists, for short correspondence, where such accommodation is desired.

VACCINATION MEDICAL OFFICERS AS PROSECUTORS.—*Appropos* of the subject, we are informed that the Sheffield Board of Guardians decided at their meeting on Wednesday last that they would not permit their vaccination officers to prosecute, at their own discretion, parents who object to have their children vaccinated. No prosecutions will be permitted unless specially sanctioned by the Board, and then only after each case of non-compliance with the Vaccination Act has been fully considered. There was an evident disposition on the part of several of the guardians that prosecutions should not be resorted to.

J. E. R.—Yes, an authority upon the subject.

STUDENT.—We shall publish full particulars in due course; some of the arrangements have not been settled yet.

IS IT A FACT?—Last week, at the annual meeting of the Devonshire Association for the Advancement of Science, Mr. W. Pengelly, F.R.S., read a humorous paper entitled, "Is it a fact," in which he pointed out how statements passing from one person to another became frequently distorted and twisted in the most curious manner. He related some very interesting and amusing specimens of the sort, evidencing the credulity of people in general, and how prone most were, particularly when scandal was the topic, to believe and add thereto a few gentle touches of their own.

"A CASE OF REAL DISTRESS."

We have great pleasure in acknowledging the receipt of the following sums in reply to the appeal in our last. Some of the subscribers to their donations have added a kindly sympathetic note, and the wish that it were more. Of the few who have contributed, not one has asked the name, which we scrupulously withheld in our last, in deference to the feelings of the recipient. Since then this gentleman, seeing the appeal in our columns quoting a portion of his own letter, has written a most touchingly grateful letter, acknowledging the unexpected kindness, and begging us that if any money be sent in response, we will bestow it upon others who may possibly be worse off than himself; as "he has just received a small sum to supply immediate wants." Of course we cannot think of adopting this course, and we assure him that his natural dread lest it should be known that he is the recipient of charity, need not trouble him for an instant. It has not, and will not be known beyond ourselves.

Dr. W. P. Harrison, F.R.C.S., Ilkley, Yorkshire, £1; Dr. Barr Meadows, L.R.C.P., M.R.C.S. Lond., £1 1s.; A. A. T., London, 2s. 6d.; G. C., Dundee, 5s.; W. H., Church Stretton, 2s. 6d.; M. L., Howth, 8s.

COMMUNICATIONS have been received from:—Dr. Cullen, Kilmeaden. Dr. McKeogh, Thurles. Dr. Bodkin, Tuam. Dr. Burrows, Riverstown. Dr. Lawler, Tralee. Mr. Connolly, Mullinarnham. Mr. Brennan, Dublin. Mr. Allen, Dublin. Dr. Butcher, Dublin. Dr. Crane, Mullinavett. The Secretary General Post Office, Dublin.

ERRATA in the "Contributions to the Pathology of the Blood," in the last Number (July 31st, 1877).—In the 2nd line, for "Archiv. f.uso Dermatologie, &c.," read "Archiv. für Dermatologie, &c." In note at the bottom, for "II. Heft des Wiener M. Jahrbücher," read "II. Heft des Wiener Medicinischen Jahrbücher." In the 4th line from the top, for "to learn for," read "to learn by." Page 96, 1st column, 23th line from the top, for "an enucleus," read "a granule." 32nd line from the top, for "I will now describe the variety of forms," read "I will not describe the varieties of form." 42nd line, for "fibrine," read "fibrin." 14th line from the bottom, for "seldom to be seen," read "seldom to be sure." Second column, same page, 29th line from the bottom, read every addition of fluid puts the form-elements in motion. In note at the bottom, for "Handbuch des Gelvebelne," read "Handbuch der Gewebelehre." Page 97, at the end of the 9th line from top, instead of a period, a comma. 2nd line from the bottom, for "the characteristic one indicated," read "the characteristics are indicated."

WEST LONDON HOSPITAL.—Operations, 2 P.M.

VACANCIES.

Westminster Hospital. House-Surgeon. Board and residence, without salary.
Shoreditch, East London, Parish of St. Leonard. Dispenser. Salary £120.
Westminster Dispensary, Soho. Resident Medical Officer. Salary £100.
Notting-hill Dispensary, W. Resident Medical Officer. Salary £100.
Surrey Dispensary, Southwark. Physician.
Uttoxeter Union. District Medical Officer. Salary £32, exclusive of fees.
Liskeard Union, Cornwall. Medical Officer. Salary £65, exclusive of fees.
Sudbury Union, Suffolk. Medical Officer. Salary £41, exclusive of fees.
Newtown and Llanidloes Union. Medical Officer. Salary £30.
Northampton General Infirmary. Dispenser. Salary £100.
Dover Hospital. House Surgeon. Salary £20.
Ventnor Hospital for Consumption. Resident Medical Officer. Salary £30.
Ladies Medical College, London. Lectureship in Midwifery. Amount guaranteed by fees, £120 per annum. (See advt.)

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

A Manual for Hospital Nurses. By E. J. Donville, L.R.C.P. London: J. and A. Churchill.
The Graft Theory of Disease. By James Ross, M.D. London: J. and A. Churchill.
On the Functional Diseases of the Urinary Organs. By D. Campbell Black, M.D. London: J. and A. Churchill.
On Diet and Regimen in Sickness and Health. Fifth Edition. By Horace Dobell, M.D. London: Lewis.
Address before the Carolina Medical Association. By Dr. F. P. Porcher.
La Presse Médicale Belge. Pacific Medical Journal. Cincinnati News. Indian Medical Gazette. Allgemeine Wiener Medizinische Zeitung. British Journal of Dental Science.

APPOINTMENTS.

BLAIR, J. O., M.D., Medical Officer and Public Vaccinator for District No. 2 of the Newbury Union.
BROWN, H. J., F.R.C.S., Medical Officer for the newly instituted Out-door Department of the City of London Lying-in Hospital.
BRUCE, R., L.R.C.S. Ed., a Medical Officer for the newly instituted Out-door Department of the City of London Lying-in Hospital.
BURCHELL, P. L., M.B., F.R.C.S., Consulting Surgeon for the newly instituted Out-door Department of the City of London Lying-in Hospital.
CHESMAN, T., F.R.C.S., re-elected a Surgeon to the Sheffield Hospital.
FOWLER, R., M.D., M.R.C.S., a Medical Officer for the newly instituted Out-door Department of the City of London Lying-in Hospital.
GREENWOOD, M., M.D., a Medical Officer for the newly instituted Out-door Department of the City of London Lying-in Hospital.
GRIFFITH, J. C., M.B., a Medical Officer for the newly instituted Out-door Department of the City of London Lying-in Hospital.
HALSE, C. S., M.D., a Medical Officer for the newly instituted Out-door Department of the City of London Lying-in Hospital.
MACKENZIE, L., M.R.C.S., House-Surgeon to the London Hospital.
MACLEAN, A., L.S.A., House-Surgeon to the Rotherham Hospital and Dispensary.
MAJOR, H. C., M.B., C.M.; late Clinical Assistant at the West Riding Asylum, Wakefield, promoted Assistant Medical Officer.
ODLING, T. F., M.R.C.S., Junior Resident Medical Officer to the Royal Free Hospital, Gray's Inn Road.
POWELL, J. T., M.D., L.R.C.P.L., a Medical Officer for the newly instituted Out-door Department of the City of London Lying-in Hospital.

CLINICAL LECTURE ON A CASE OF LOOSE SCAPULA.

By C. HANDFIELD JONES, M.B.Cantab., F.R.S.,
Physician to St. Mary's Hospital.

M. A. N., æt. 37, seen Feb. 21st, 1872. Has been suffering with her right arm twelve months; the disorder came on gradually; she had not strained or injured the arm in any way before. Had rheumatism some years ago, but has no traces of it now, unless the arm affection be regarded as such. Health always rather weakly. Catamenia regular, rather scanty. Mouth is dreadfully nasty in mornings. Bowels open. Was in St. George's Hospital four months ago in the surgical wards; was galvanised, and had cold shower bath, but did not get any better. She can't use her right arm, "has no power in it in the least, it aches so much." Most pain is felt at upper and back part of right shoulder; there is a good deal of tenderness in this situation when the part is handled. She can move the arm a good deal in almost any direction, but almost any movement causes some pain, and extensive movement much pain. No dislocation of shoulder joint. Right forefinger quite dead the last two days; it is, however, tolerably sensitive this morning. Grasps more strongly with left than with right hand; the effort causes a 'drawing' pain up right forearm. Right hand is colder than left. The scapula is often most markedly displaced; the spinal border is thrown backwards and outwards so as to project considerably. The above notes were taken just after she had been examined by a skillful hospital surgeon, who pronounced her case to be one of dislocation of the "latissimus dorsi" muscle from the lower angle of the scapula, and that the application of a bandage round the thorax to keep the bone in its place was the only measure likely to afford any relief. Without by any means discrediting this opinion altogether, I was not inclined to

adopt it exclusively, for the reason that there existed evidently so much sensory and motor disorder that I could not but think that if these were amended there was considerable hope that the functional power of the limb might be in great measure restored.

She was admitted into St. Mary's under my care, Feb. 24th, and I took the following notes:—As she sits up in bed the right scapula's inner border projects abnormally to a great extent, and its upper and inner angle is drawn upwards, while its lower is tilted backwards and separated more or less from the chest walls. Her dorsal spine is curved a good deal backwards. She finds it difficult to get up in bed, it causes her pain in the lower dorsal or lumbar region, and hurts the shoulder too. When her back is not supported the scapula projects much more; its inner border and upper angle are more elevated. When she takes a deep breath the right lower ribs rise well, and the scapula remains pretty well *in situ*. Pressing the right shoulder hurts her very much, and so does moving it passively in any direction. The displacement of the scapula seems to be produced by spasm of the rhomboid muscle and levator anguli scapulae. In deep inspiration the diaphragm descends but little; her arms are about equal in size; face rather red; she perspires very much, even when lying in bed. Port, 4 oz.

Strychnia, gr. 1-20;
Acidi Nitric, ℥ ij.;
Spt. Chlorof., ℥ x.;
Aq. ʒi. i.d.;

Ord. D. Porter, Oj.

26th.—Inner border of scapula much approximated to spine, and its inferior angle considerably raised, so as to be two inches higher than the inferior angle of the left. Urine palish, not albuminous, feebly alkaline, with scattered flocculi floating in it. Pt. Ferri Carb. Sacch. ʒj. *ter die*.

29th.—Manner not at all fussy, spasm continues, inner edge of scapula drawn close to spine, and the bone considerably raised. I injected Morphia muriat. gr. ʒ and atropia, gr. ʒ near the spine.

March 4th.—Much less pain after the injection, feels better in herself, arm same.

Succi Conii, ℥ij.;
Aq., ℥vj., *ter die*.

Shoulder is very quiet at night. Mr. — examined the patient to-day, and ascribes the disorder to dislocation of the scapula from the latiss. dorsi. Injection repeated.

March 8th.—I inject her again at her own request. She has much less pain in arm and shoulder, and has more use of the arm. In inspiration both scapulae diverge from the median line, and the ribs rise well. When I press forcibly on the right scapula, so as to prevent the displacement of the lower angle—which otherwise is still considerable—she says it affords her great support. I have to press hard, or else the lower angle is tilted out. This tilting out takes place during the first part of the act of raising the arm, and ceases after the arm has passed the horizontal position. Faradised the serratus magnus. As she has a good deal of leucorrhœa, I order—

Zinci Chloridi, gr. xx.;
Ad Aq. Oj., pro inject.

12th.—Much better, has more use of arm, no pain in arm now, injection not needed.

14th.—Some pain in dorsal region. Liq. Opii, Sedat. ℥ x., injected at inside of posterior border of scapula.

Ri. Succi Conii, ℥ij. Repr. pulv.

18th.—Improving, urine very pale and aqueous, sp. gr. 1.007.

Ferri et Quinæ Citratis, gr. x.;
Tr. Nucis. Vomica ℥ x.;
Aq. ℥j., *t. d.*

28th.—The lower angle of left scapula is now at about the same level as the right, the posterior border is still very apt to project, and it is easy to pass the finger between the bone and the ribs. The rhomboid muscle is seen to twitch occasionally. She says she is twice the person she was, she can use the arm much better, but still feels that the scapula is not fixed enough, and that she can not exert the arm as she might if the scapula were more fixed.

April 2nd.—Can do some needle-work now, which she has not done for three months; using cold plunge bath daily since 31st ult.

April 8th.—The arm is now so well that she could have kept her last place if it had been as well then as it is now, she can do almost anything with it.

22nd.—Can now take up a kitchen chair and hold it out at arm's length in her right hand; when she was admitted she could not take an empty plate off the table, or a cup of tea without supporting the right arm with the left hand. The lower angle of the scapula is still prominent when the arm is passive, but when I ask her to raise the arm it passes outwards and remains close to the thorax. Going to Walton.

Remarks.—It was quite evident in this instance that the loss of power in the arm was largely dependent on the want of fixity in the scapula, and that the main point to be aimed at was to restore the latter, so that the humerus might have a steady *point d'appui* whereon to execute its movements. The question then arose how to do this. The chirurgical view referred the looseness and liability to displacement of the scapula to a purely mechanical defect, viz., the slipping off of the upper edge of the latissimus dorsi muscle from its usual position across the lower angle of the scapula, and consistently dismissed the sorrowful patient with the dictum that there was no room for curative treatment, but that relief might be afforded by a properly applied bandage. The Medical view on the other hand, regarded defective action of the muscles as the cause of the want of fixity of the scapula, and proposed to remedy this by restoring to the muscles more tone and vigour. The surgical view took little notice of the pain caused by any movement of the arm, and by pressing the shoulder or

passive movement of the part, and made little count of the spasmodic action of the rhomboid and levati ang. scapula. On the Medical view, these symptoms were very significant of failure in nervo-muscular power. The pains were recognised as those of myalgia, and the spasmodic contractions of the muscles as the usual results of hyper-excitability generated by weakness. The Medical view appeared to be confirmed by the argument that, if the latissimus dorsi was to be regarded as a swathe or bandage, retaining the scapula *in situ*, it would be essential that both its extremities should be fixed, whereas it was evident that only the spinal attachment usually was so, the humeral remaining mobile. Under these circumstances, even admitting that the muscle in question was displaced, it seemed probable that the loss was of no material importance. On the Medical view, the most important agents in retaining the scapula *in situ* were the rhomboid and serratus magnus muscles, which attach the posterior costa respectively to the spine and ribs, and keep the venter applied by the resultant of their combined forces against the posterior surface of the thorax. The marked projection of the posterior costa afforded proof that the above mentioned muscles were acting defectively, while the tilting outwards of the lower angle was probably caused by the supra-spinatus and deltoid, whose action continued to the last to preponderate over that of the inward and outward braces. The Medical view is also supported by the fact that, it is common for the latissimus dorsi to take some fibres of origin from the lower angle of the scapula. This surely implies that the scapula is fixed during the contraction of the latissimus dorsi. Indeed, as the fixity of the scapula is necessary to the proper action of the arm muscles, it seems that in any case where the latissimus dorsi is in action we must assume the previous fixation of the scapula.

The only objection which seems of some force against the Medical view, is that the serratus magnus during inspiration appeared to act fairly well. In answer to this it may be said that although the muscle might function well as part of an excito-motor apparatus, in response to a physical stimulus, the case might be very different, when it had to act in concert with a number of purely voluntary muscles. The medulla oblongata is nearer to the spinal origin of the external respiratory nerve than the corpi striat., and the vitality of its nerve cells is more persistent and steady than that of the higher centre, so that it is quite conceivable that the contractions determined by its influence, might be orderly and sufficient, when those originated by another centre were defective. Moreover, it is to be remarked that it is not so much the faculty of active contraction which was at fault in this instance, as of that minor and more sustained contraction which we designate '*tone*,' or with Todd and Bowman passive contraction, and which is probably dependent on a normal state of the nerve cells of the gray matter of the spinal cord where the nerve roots are implanted. By this rather than by active contraction the several parts of the body are kept in their proper positions.

The view I am advocating is that adopted by M. Duchenne, and Mr. Barwell, no mean authorities, as you may read in a case described by the latter in *Path. Trans.*, XVII, 436.

The success of the treatment suggested by the Medical view of the pathology was striking and testifies materially to the correctness of the latter. At the same time the surgical suggestion could it have been duly carried out would certainly have been of much benefit, and I would have you bear it in mind if you have to deal with such cases. The condition was, I believe, only remarkable from the existence of an unusual amount of nervo-muscular disturbance in a separate locality. The cause of this was no doubt in great measure over-exertion, a frequent cause of similar troubles, the exhaustion as it so often happens not generating mere paresis, but paresis and hyperexcitability. I should add, however, that the patient had probably an hereditarily infirm nervous system, as a sister suffers from a well marked quasi-hysterical cough.

CLINICAL REMARKS ON CLIMATE AS REGARDS THE PARSEES.

By DR. OGLE.

In a clinical lecture containing observations upon the capacity of the human body to bear varieties of temperature and climate, Dr. Ogle alluded to the case of certain Parsees who were sent over by the Government from Bombay to be educated and to graduate in London as Medical men, with a view to their entrance into the army as surgeons. When some of them, who were highly intelligent and apt in learning their profession and acquiring a knowledge of the Latin language and other collateral subjects, were on the point of graduating, it was determined at head-quarters that for certain reasons these Parsees ought not to enter the army. The Parsees themselves understood that those reasons were political, but the plea put forward was that they would be unable to endure the rigors of such climates as they would, as surgeons in the army, have to be sent to. To show the untenability of this view much correspondence arose, and the following were some of the statements that were made by those who had much knowledge of Parsees in general, and of the individuals in question, and were competent to speak regarding them.

Referring to two Parsee youths, of the ages of ten and twelve, who, when brought to England, were at once placed at a boarding school in Liverpool, the schoolmaster, when they had been about a year with him, writing in May, 1861, remarked "that in spite of the first winter which they spent in England, being one of the severest on record, they have never had the least ailment of any description, nor have they, on the score of health, been absent one single day from their school duties. So far indeed from their seeming to suffer from our climate, they contrasted most favourably with a nephew of my own who was born in Newfoundland, and who has been about a year and a half in England. In short they seem as well able to encounter the changes of our climate as any boy in my school, and much better than many."

About the same date, a Medical man, living in Liverpool, who was in large practice in that town, and had charge of a jail, wrote as follows:—

"You ask me," he observes, "my opinion whether the natives of India are capable of enduring the rigors of a cold climate for a lengthened period of time? I have no hesitation in answering in the affirmative. If the question applies to the climate of England, I should say that in the cases which have fallen under my observation of Parsees resident in Liverpool and its neighbourhood, the constitution seemed invigorated and strengthened by the change, and I have no doubt that they are quite as able to endure the climate of Europe or Canada, as Englishmen are that of India."

CLINICAL REMARKS ON SOME VARIETIES OF FEVER.

By DR. OGLE.

WHEN speaking of varieties of fever, Dr. Ogle referred to a form which had been described to him by a non-medical friend as having existed in the neighbourhood of Taunton. It went by the name of the "Hill Fever," and appears to have prevailed from the spring of 1853 to that of 1858, in one village, which consisted of a small cluster of houses near the church. In reference to this fever, about which he made enquiries, Dr. Cordwent, of Taunton, a former pupil of St. George's, had been so kind as to furnish Dr. Ogle with the following particulars. In a letter written in September, 1870, that gentleman remark

of a fever or fevers which existed about sixteen years ago, and through seven or eight years subsequent, that they were epidemic in the vicinity of Taunton. "One of these was very virulent in character, and attacked persons residing on the slopes of secondary elevations, having a northerly aspect and a geological formation of clay over blue lias, that association undoubtedly existed in the vale of Taunton, for during the successional periods of the first two forms of fever I was officially associated with Medical duties on both sides of the valley. On the West Monkton side, *i.e.*, the north side (red-sand stone) having of course a south aspect, not a case occurred; but on the opposite side (clay and blue lias) having a south aspect, fever, such as I will briefly indicate from memory, was frequent, and when well marked, as it mostly was, was fatal in about 20 per cent. The onset of this malady was so insidious, that during some days (usually five or six) the affected person scarcely complained of illness; and even later, when experience proved the case extreme, lassitude was usually what the patient spoke of. Sometimes there was pain in the head, but there was neither thirst nor a flushed countenance. The appetite diminished, but far from ceased. The pulse beat was not increased in number, but was lessened in force. The temperature of the hand was nearly always lower than in health. Usually within a fortnight the fauces became much affected, as also did the parotid glands (or rather, as I thought from grouping the symptoms the entangled absorbent glands). In the latter stages the tongue *sometimes* became dry, but it was always tremulous when the disease had completely developed, and so were the hands. Neither the intellect nor the respiration was usually much affected—at least the mind was congruous, but very slowly resumed its faculty after sleep. Pain was little complained of. Contemporary with the later season, and the dying out of this fever and co-local with it, and doubtless another phase of its toxæmia, was a fever whose first declaration—even before ordinary malaise, was a scarlet minute papular eruption generally affecting the entire surface. It did not occur in patches. Sore throat, but not always severe, was connected with this eruption, which would frequently disappear and reappear during three or four weeks at irregular intervals of two or three days without the throat affection or other internal disorder being apparently increased. On the third or fourth day there was invariably a craving for cider, which rarely continued more than two days. This disease, of which I have just given the outline, was not diphtheria; that appeared a year or two later, and so far as my observations went, in the same side of the country. I heard of diphtheria otherwise occurring in the private practice of others, but neither in public nor in private practice, did a case occur to me, except on the slope of the southern side of the village. Other circumstances being equal, the modes of living were similar on each side—the water was chalybeate in the district then most pregnant of the disease; whether as a coincidence or cause, I cannot say. I doubt if direct medicine did any service, but I believe air charged with chlorine gas did. Subsequent to the diphtheritic invasions was that dire one of cerebro-spinal fever. This latter seemed to obey no law of locality, and certainly none of contagion; it attacked fewer persons than did either of the other two forms spoken of, but was even more deadly. I need not attempt to describe its phenomena—these are familiar to you, but I believe there was an alliance in those fevers more intimate than that of mere succession. In the first of the series, besides the tremulous hand and tongue, there was sometimes paralysis of the urinary bladder, whilst among the second or diphtheric, not unfrequently there occurred cases of insidious debility, in which a zymotic toxæmia could scarcely be proved by direct manifestation, but was suspected chiefly because attacking the young and previously healthy, and because of the course it ran. In such occasional cases there was no sore throat, nor eruption, and scarcely febrile action in the ordinary sense of the term, yet patients so affected not unfrequently died

calmly, and of no evident cause, but probably there became engendered on some of the nerve-centres an extra intensity of poison, or the power of excreting it had become less. At the time when cerebro-spinal fever was rife here, that is, from 1863 to 1865, there was certainly an increase, and a great increase, of cases of other cerebral disease, such as persistent mental delusions, and of sub-acute mania. I often mentioned my convictions and the evidence to other Medical men, and though the observation was not corroborated, I am convinced of the subtle fact, and if an epidemic *proneness* to cerebral disease did then exist, as I have no doubt it did, and no especial horror, as that of war, acting on the public mind produced it, it could only be attributed to some subtle toxemia taking its especial lien on the sensoria. In neither of the nine or ten cases of cerebro-spinal fever which between the years of 1864 and 1866 here and there fell under my care, was there any eruption, or if existing, it was so slight as not to attract attention. I ought to have mentioned that the fever whose season preceded that of diphtheria, had in its earlier stages a markedly intermittent character; so much so, that if the locality and season had been suitable, many cases may at first have been mistaken for cases of ague."

ON A CURIOUS FORM OF INJURY TO A FEMALE PRODUCED BY A GOAT.

By Staff Assistant-Surgeon W. CURRAN.

THE following particulars of a very rare, if not absolutely unique, injury to the recto-vaginal parts of a young female are so peculiar as to justify their reproduction in full in this place, and warrant the belief that they are without a parallel in the records of our art; as such they are offered for publication in this Journal, and I shall be glad to hear of any instance in point that may have transpired during the reading, or occurred in the practice of any of my brethren. I am indebted for them to the courtesy of my friend Dr. Hayes, of Tralee, who attended the girl referred to in them, and from whose dictation they were taken down by me on the occasion of my late visit on election duty to that place. I have never seen myself, nor can I find mention made in any of the books to which I have access, of any, similar case, and the Medical men to whom I have mentioned it have manifested equal ignorance and surprise. That the accident occurred, as detailed more fully below, is, however, quite certain, and the result is such as does credit to the judgment and skill of my informant.

"M. A., *æt* 20, unmarried, of delicate organization and somewhat cachectic habit, was the subject of copious leucorrhoeal discharges, occasional paroxysmal headache, and almost constant lateral pain, which however did not 'lay' her up, or otherwise incapacitate her for the discharge of her domestic duties, and she sustained the injury referred to above while in the execution of one of these. The circumstances under which this occurred are briefly as follows:—It appears that, while carrying a bundle of clothes, which prevented her from seeing objects in front of her, she had occasion to pass over a stile that interposed between the garden and her house, and at the opposite side of which a goat was lying. Irish girls of her class do not, I believe, usually wear drawers, or other protection between the chemise and the trunk, and in the instance under review no such dress was used. The great apertures of the body were therefore fully exposed by the effort she made to pass the stile, and while in that enforced attitude, the goat disturbed by her approach, suddenly started up, and, in doing so, thrust his horn forcibly through the anus for about two or more inches up the rectum, thence forcing it through the bowels and intermediate parts, he pushed it into the vagina, just

above insertion of hymen, and withdrawing it as she flinched or fell back produced an openness, which included the lower part of the rectum, and the vagina, the sphincter ani, the fourchette, and perinæum. A large jagged wound which bled very freely, and caused excruciating pain, was the result; she fainted on the spot from shock and hæmorrhage, and had to be carried in an unconscious state to bed. Such is the modesty of our countrywomen, or so remote was the residence of the sufferer, that Medical aid was not procured at once by her attendants, and, when seen three days afterwards by my friend, she was very feverish, with a pulse of 120, a hot burning skin, uncontrollable irritability of stomach, some tympanites of the belly, and considerable tumefaction of the perinæum and vagina. Some antiphlogistic treatment, combined with local applications, having reduced the fever and relaxed the swelling, the edges of the wound were renovated, and brought together with three deep and four superficial wire sutures. Rest in the recumbent position was enjoined, and opium was exhibited to control the bowels. On removing the sutures the parts were found to be cicatrised—not, however, so firmly as to retain their union, for a small fistula subsequently appeared, which however soon yielded to applications of nitrate of silver; and in due course closed up. The perinæum is now shorter than it was, and the opening of the vagina is, perhaps, a trifle larger. With these exceptions, however, and some puckering between it and the anus, there is no disfigurement or deformity, and the girl's general health is as good, or perhaps better, than it was before."

Such in substance is the communication made to me by Dr. Hayes, who has kindly authorised me to make any use of it I might think fit; and I think I cannot better consult his wishes, or fulfil my own, than by placing it on record, and bespeaking for my very imperfect description of it that courtesy and consideration which its interest and my incapacity may appear to command or suggest.

Hospital Reports.

CASHEL FEVER HOSPITAL (Under the care of Dr. LAFFAN).

Defaced Typhoid—Death on the 63rd day from Atonic Ulceration.

J. C., *æt* 60, a butcher's man, was admitted into the Cashel Union Hospital, July 16th, 1871, for vomiting and diarrhoea. A suspicion of fever having been excited by the persistence of the diarrhoea, he was sent on the 19th to the Cashel Fever Hospital. The man had none of the symptoms proper to enteric fever. There were no rose spots, nor did the tongue, abdomen, or stools present any definite indication of that form of fever. The pulse varied between 90 and 100. Signs of chronic bronchitis extensively prevailed. The diarrhoea persisted, alternating with occasional constipation. The pulse, which was at first 100, fell during part of the time to 80, and rose again during the last weeks to 100 and 108. The temperature, which was at the commencement but $96\frac{3}{4}^{\circ}$, fell during the intermediate period to 90° , and again rose towards the close to 94° . He slept well during the day, but poorly at night; he was much harassed during the entire period with the bronchitic symptoms. He began to complain during the last fortnight of pain in the abdomen, but there was no gurgling or tympanitis. The stools at this time assumed somewhat of the ochrey character, and were mixed with green and shreddy matters and some blood. The appetite, which for a long time was fair, failed; he became more and more emaciated, and at length died quietly on the 27th September.

Autopsy twelve hours after Death.—The peritoneal cavity was healthy, but portions of the peritoneal surface of the small intestines were very vascular. The stomach and duodenum were healthy, the spleen was slightly, the mesenteric glands immensely, enlarged. The entire small intestines, particularly the lower portion of the ileum, were lined here and there with unhealthy ulcers, having eroded angry edges and foul surfaces. Many of these involved Peyer's patches, while most of them had eaten through all but the peritoneal coat of the intestines. There were appearances of cicatrices in some places, but they were not sufficiently distinct for positive identification. The lining membrane in the intervals between the ulcerated patches was congested, and in some places the entire walls of the intestines were thinned. The largest ulcerated patch was placed at the junction of the ileum and the cæcum. The ulceration extended into the ascending and transverse colons, and one or two ulcers with inflamed intermediate patches were present even in the rectum. The lungs and pleura were extensively diseased. The case presents the following features of interest:—

1st. The duration, sixty-three days, as compared with 24.6, the mean noted by Murchison.

2nd. The temperature, which never attained the elevation laid down by writers on typhoid fever.

3rd. The disguised form which rendered positive diagnosis impossible.

4th. The non-occurrence of perforation, or of much hæmorrhage, either or both of which might have been expected from the great extent of ulcerated surfaces.

STUDENTS' COLUMN.

SYNOPTICAL REVIEW OF THE OFFICIAL PREPARATIONS OF THE BRITISH PHARMACOPEIA.

By W. HANDSEL GRIFFITHS, PH.D., L.R.C.P.,
L.R.C.S. Edin.,

Assistant-Librarian Royal College of Surgeons in Ireland.

CLASS V.—SOLUTIONS OF THE INORGANIC SALTS.

Liquor Ammonia Acetatis.
" Ammonia Citratis.
" Antimoni Chloridi.
" Arsenicis.
" Arsenic Hydrochloricus.
" Bismuthi et Ammonia Citratis.
" Ferri Perchloridi.
" Ferri Perchloridi Fortior.

" Hydrargyri Perchloridi.
" Magnesia Carbonatis.
" Plumbi Subacetatis.
" Plumbi Subacetatis Dilutus.
" Potassa Permanganatis.
" Soda Arseniatis.
" Zinci Chloridi.

We will study consecutively the mode and *rationale* of preparation, the strength, specific gravity, character, and tests of the foregoing—

Preparation.

Liquor Ammonia Acetatis.—This is commonly known as "Mindererus's Spirit," and is a solution of acetate of ammonia ($\text{NH}_4\text{C}_2\text{H}_3\text{O}_2$) in water. It is made by adding gradually powdered carbonate of ammonia to 10 fluid ounces of acetic acid until a neutral solution is formed, and then adding $2\frac{1}{2}$ pints of water.

The following is the reaction which takes place:—

Liquor Ammonia Citratis is a solution of citrate of ammonia ($\text{NH}_4)_3\text{C}_6\text{H}_5\text{O}_7$) in water. It is made by adding to a solution of 3 ounces of citric acid in 1 pint of water strong solution of ammonia until the liquid is neutral to test paper. The reaction is expressed thus—

Liquor Antimoni Chloridi.—This, which is often known as "Butter of Antimony," is a solution of trichloride of antimony (SbCl_3) in hydrochloric acid. It is prepared by dissolving 1 pound of black antimony (Sb_2S_3) by the aid of heat in 4 pints of hydrochloric acid, and boiling down to the bulk of 2 pints.

During the reaction the materials are directed to be placed beneath a flue with a good draught, in order to carry off the sulphuretted hydrogen gas.

Liquor Arsenicalis.—Commonly known as "Fowler's Solution." It is made by dissolving, by the aid of heat, 20 grains each of arsenious acid and carbonate of potash in 10 ounces of water; when cool adding 5 drachms of compound tincture of lavender, and finally adding distilled water to make up the bulk to 1 pint. The solution of arsenious acid in water is facilitated by the presence of the alkaline carbonate, which is slowly decomposed by it. The officinal solution therefore contains a small quantity of arsenite of potash,—

The compound tincture of lavender is merely added as a colouring and flavouring agent in order to prevent mistakes.

Liquor Arsenici Hydrochloricus.—Made by boiling 80 grains of arsenious acid with 2 drachms of hydrochloric acid and 4 ounces of water until it is dissolved, and then adding water to make up the bulk to 1 pint (a).

Liquor Bismuthi et Ammonia Citratis.—Mix 2 ounces of nitric acid with 1 ounce of water, and add 430 grains of pure bismuth in successive portions. When effervescence ceases heat moderately for 10 minutes and then decant. Evaporate to 2 ounces, and add 2 ounces of citric acid dissolved in 4 ounces of water. Add gradually solution of ammonia until the precipitate at first formed is dissolved, and the solution is neutral or slightly alkaline. Dilute with water to 1 pint.

In the above process trinitrate of bismuth is first formed; on adding ammonia to this, oxide of bismuth would be precipitated, were it not that by the previous addition of citric acid, citrate of ammonia is formed in which oxide of bismuth is freely soluble. The nitric acid, which is set free, is saturated by the excess of ammonia present, and, hence, the liquor contains nitrate of ammonia, as well as citrate of bismuth and ammonia. It differs somewhat from the celebrated "Schacht's Solution of Bismuth."

Liquor Ferri Perchloridi Fortior.—An aqueous solution of perchloride of iron (FeCl_6). Dissolve 2 ounces of iron wire in a mixture of 8 ounces each of hydrochloric acid and water by the aid of a gentle heat. Filter, add 4 ounces of hydrochloric acid and 9 drachms of nitric acid, and heat until red fumes are evolved, and the liquid becomes orange brown. Evaporate down to 10 ounces.

The first stage in the above process is the formation of protochloride of iron by the action of hydrochloric acid, or the iron wire.

(a) We may here mention another arsenical liquor which, although not now officinal, was in the *Dublin Pharmacopœia*, and is still so very generally used as to warrant special notice *via*, *Liquor Arsenici et Hydrargyri Hydriodatis*, or "Donovan's solution." It is made by triturating together 6 grains of arsenic, 16 grains of mercury, 5 1/2 grains of iodine, and 1 drachm of alcohol, until a dry mass is obtained; this is then rubbed with 8 ounces of water in successive portions, and then heated to ebullition; when the solution has cooled it is filtered, and as much water is added as will make up the bulk to 8 ounces and 6 drachms. In this preparation the iodine combines with the arsenic forming the triiodide (AsI_3), and with the mercury forming the periodide (HgI_2). One fluid drachm of it contains 1-12th grain of arsenic, 1-4th of mercury, and 3-4ths grain of iodine.

This protochloride (containing excess of hydrochloric acid) is then converted into perchloride by the action of nitric acid.

Liquor Ferri Perchloridi.—Made by diluting 1 part of the strong solution with 3 parts of water.

Liquor Ferri Pernitrat.—An aqueous solution of pernitrate of iron ($\text{Fe}_2, 6\text{NO}_3$). Dissolve 1 ounce of iron wire in a mixture of $4\frac{1}{2}$ ounces of nitric acid and 16 ounces of water, moderating the action, if necessary, by adding more water. Filter, and add water to $1\frac{1}{2}$ pints. In the reaction which ensues pernitrate of iron is formed, water is produced, and nitric oxide evolved.

Liquor Ferri Persulphatis.—An aqueous solution of persulphate of iron ($\text{Fe}_2, 3\text{SO}_4$). Dissolve 8 ounces of sulphate of iron in a mixture of 6 drachms of sulphuric acid and 10 ounces of water by the aid of heat. Add 6 drachms of nitric acid diluted with 2 ounces of water. Concentrate by boiling until the mixture changes from black to red. As long as the solution gives a blue precipitate with red prussiate of potash, add a few drops of nitric acid, and renew the boiling in order to convert all the sulphate into persulphate. When cold add water up to 11 ounces.

When nitric acid is added to a solution of sulphate of iron in sulphuric acid, the proto is converted into the persalt, and nitric acid is developed.

The nitric oxide is not at once evolved, but is absorbed by, and blackens any protosulphate which may be present. This black compound is afterwards decomposed.

Liquor Hydrargyri Nitrat.—A solution of pernitrate of mercury ($\text{Hg}2\text{NO}_3$). Dissolve 4 ounces of mercury in a mixture of 5 ounces of nitric acid and $1\frac{1}{2}$ ounces of water without heat. Then boil gently for 15 minutes to ensure the formation of the pernitrate, and to cause the expulsion of the nitric oxide.

The reaction is thus expressed :—

Liquor Hydrargyri Perchloridi.—An aqueous solution of the perchloride of mercury (HgCl_2). Dissolve 10 grains each of perchloride of mercury and chloride of ammonium in 1 pint of water.

The chloride of ammonium is to increase the solvent power of the water.

Liquor Magnesiæ Carbonatis.—To a solution of 2 ounces of sulphate of magnesia in $\frac{1}{2}$ pint of water heated to boiling point, add a solution of $2\frac{1}{2}$ ounces of carbonate of soda in $\frac{1}{2}$ pint of water. Boil until carbonic acid is no longer evolved. Collect the precipitated carbonate of magnesia on a filter, and wash until the washings give no precipitate with chloride of barium (absence of a sulphate). Mix the washed precipitate with 1 pint of water, and saturate it with washed carbonic acid gas passed in under slight pressure. Filter the liquid after 24 hours to remove any undissolved carbonate of magnesia, and again pass carbonic acid gas into the filtered solution. Preserve in a well stoppered bottle.

The following is the reaction :—

In this reaction the water decomposes the carbonate of magnesia, some of the carbonic acid of which is given off, and a combination of a hydrate and a carbonate of magnesia results.

This solution resembles "Murray's Fluid Magnesia."

Liquor Plumbi Subacetatis, commonly known as "Goulard's Extract." Boil 5 ounces of acetate of lead and $3\frac{1}{2}$ ounces of oxide of lead in 1 pint of distilled water for

half an hour. Filter and when cold add water up to 20 ounces. Keep in stoppered bottles. The acetate of lead combines with the oxide of lead to form a mixture of oxyacetates, which is collectively known as the subacetate, thus,—

Liquor Plumbi Subacetatis Dilutus, commonly known as "Goulard Water." Mix 2 drachms each of solution of subacetate of lead and rectified spirit, with $19\frac{1}{2}$ ounces of distilled water; filter and keep in a stoppered bottle.

If this preparation be not made with distilled water it becomes milky from the formation of other salts of lead, as the carbonate and sulphate.

Liquor Potassæ Permanganatis.—Similar to, but half the strength of, "Condy's Disinfecting Fluid." Made by dissolving 80 grains of permanganate of potash (K Mn O_4) in 1 pint of distilled water.

Liquor Sodæ Arseniatis.—Dissolve 4 grains of arseniate of soda (rendered anhydrous by a heat not exceeding 300°) in 1 ounce of water.

Liquor Zinci Chloridi.—Represents "Sir W. Burnett's Disinfecting Fluid." Dissolve 1 pound of zinc in a mixture of 44 ounces of hydrochloric acid, and 1 pint of water by the aid of gentle heat until gas is no longer evolved. Boil for half an hour, add water to supply the loss by evaporation, cool, filter. Add solution of chlorine gradually with frequent agitation, until a permanent odour of chlorine is acquired by the liquid. Add $\frac{1}{2}$ ounce of carbonate of zinc gradually until a brown sediment appears. Filter, and evaporate down to 2 pints.

The following is the reaction :—

The object of the chlorine is to free the zinc from iron by converting the latter into perchloride, thus—

This perchloride is then, by the action of carbonate of zinc, converted into the brown peroxide and is precipitated as such, thus—

STRENGTH.

<i>L. Arsenicalis</i>	} 1 in 120 ($\frac{1}{4}$ grains to the ounce).	
<i>L. Arsenici Hydrochloricus</i>		
<i>L. Sodæ Arseniatis</i>		
<i>L. Potassæ Permanganatis</i>		
<i>L. Ferri Perchloride Fortior</i>		1 in 1.
<i>L. Ferri Perchloridi</i>		1 in 4.
<i>L. Ferri Pernitrat</i>		1 in 6.
<i>L. Magnesiæ Carbonatis</i>		1 in 37.
<i>L. Plumbi Subacetatis Dilutus</i>		1 in 80.
<i>L. Hydrargyri Perchloridi</i>	1 in 960.	

Liquor Magnesiæ Carbonatis contains 13 grains of carbonate in the fluid ounce; one fluid ounce of *Liquor Bismuthi et Ammonii Citrat* contains 24 grains of oxide of bismuth, and one fluid ounce of *Liquor Zinci Chloridi*, contains 366 grains of chloride of zinc.

Specific Gravity.

The Pharmacopœia mentions the following :—

<i>L. Antimoni Chloridi</i>	1·47
<i>L. Arsenicalis</i>	1·009
<i>L. Arsenici Hydrochloricus</i>	1·009
<i>L. Bismuthi et Ammonii Citrat</i>	1·122
<i>L. Ferri Perchloridi Fortior</i>	1·338
<i>L. Ferri Pernitrat</i>	1·107
<i>L. Ferri Persulphatis</i>	1·441
<i>L. Hydrargyri Nitrat</i>	2·246
<i>L. Plumbi Subacetatis</i>	1·26

TESTS, &c.

(To be continued.)

Transactions of Societies.

BRITISH MEDICAL ASSOCIATION.

THE annual meeting was held at Birmingham last week. President, Mr. Alfred Baker, Senior Surgeon, Birmingham Hospital.

PRESIDENT'S ADDRESS.

Mr. Baker, after welcoming the visitors to Birmingham, said:—[This address will be found in next column.]

Addresses were also delivered on Medicine by Dr. Wilks, and on Surgery by Mr. Oliver Pemberton.

The Presidents of the Sections also opened them with addresses.

MEETINGS OF SECTIONS. SECTION A.—MEDICINE.

The President (Dr. Bell Fletcher) occupied the chair.

Mr. Martin Onley read a paper on "A Case of Skin Disease of an Uncertain Type;" Dr. Arthur Ranson read one on "Bending Ribs in Forced Respiration;" Mr. S. M. Bradley, F.R.C.S., on "Tricelarian Human Heart;" and Dr. Althaus on "The Treatment of Rheumatic Gout by the Constant Galvanic Current." He advocated Moore's battery. Dr. S. Spratley also contributed a paper.

Dr. Balthazar Foster, Physician to the General Hospital, also read a paper on the Lactic Acid Treatment of Diabetes. He began by calling attention to the low bodily temperature which he had described, and the bearing which this had on the respiratory theory of diabetes. He, by means of a diagram, showed the daily excretion of sugar, water, and the body weight of the patients. He concluded, as the results of his analysis, that the lactic acid diminished the sugar excretion and the quantity of water passed. It increased the bodily temperature, and restored the skin functions.

Dr. John W. Ogle narrated the particulars of two cases which he had treated at St. George's Hospital with similar results.

Dr. Edward Woakes read a paper on "Scarlet Fever and Syphilis: a Suggestion."

Dr. Drysdale, "On Syphilis."

Mr. James Johnston, M.B., "A Case of Cyanosis, with Deficiency of the Interventricular Septum."

Dr. W. Moxon, "The Conduction of Sensation of Heat in Progressive Locomotor Ataxy."

Dr. T. L. Rogers, "Case of Pyæmia mistaken for Mania."

SECTION B.—SURGERY.

Sir W. Fergusson, President.

The following papers were read:—

Mr. Reginald Harrison, "On the Relative Value of certain Methods of Treating Stricture of the Urethra."

Mr. William Adams, F.R.C.S., "Three Additional Cases of Subcutaneous Division of the Neck of the Thigh-bone, with Remarks."

Dr. Charles Warden, 1. "On Polypus of the Ear and Perforation of the Membrana Tympani, and the instruments used in the Diagnosis and Treatment of Diseases in the Ear, at the Ear and Throat Infirmary, Birmingham; also, upon a new form of Artificial Drum." 2. "Spinal Curvature, Club Feet, and other Deformities, and the instruments used in their Treatment at the Birmingham Orthopædic Hospital."

Dr. William Stokes, "Reduction of Dislocation by a modification of Jarvis's Adjuster."

Mr. Edward Lund, "Removal of both Astragali in a Case of severe Double Talipes."

Mr. Charles Steele, "On Colotomy for Intestinal Obstruction."

Mr. T. H. Bartleet, "Two Cases in which the Femoral Artery was tied for unusual Pathological Conditions."

Mr. W. Acton, "Treatment of the advanced states of Constitutional Syphilis."

Mr. W. F. Teevan, 1. "On the Treatment of Impassable Stricture." 2. "Clinical Remarks on Stone in the Bladder." 3. "On Impotence."

Mr. James F. West, "Syphilitic Constriction of the Esophagus."

Mr. Charles Steele, "On Colotomy for Intestinal Obstruction."

Mr. George Southam, "Dislocation of the Patella on its Edge."

Dr. Charles B. Taylor, "The Modern Art of Tinting Opacities of the Cornea."

Mr. T. H. Bartleet, "Two Cases in which the Femoral Artery was tied for unusual Pathological Conditions."

SECTION C.—MIDWIFERY.

Dr. Evory Kennedy, President.

The following papers were read:—

Professor Simpson, "On the Removal of Portions of Morbid Tissue in Cases of Carcinoma Uteri."

Dr. Alfred Wiltshire, "On the Plan of Treatment of Cancer proposed by Professor Simon of Heidelberg, with Cases."

Dr. C. H. F. Routh, 1. "Further Remarks on the Treatment of Uterine Cancer, more especially by Gastric Juice." 2. "The Use of Raw Beef Juice in the Treatment of Disease."

Mr. James Thompson, "Remarks on the Use of Scæle Cornutum in cases of Labour Complicated with Feeble Action of the Heart."

Mr. Thomas Chambers, M.R.C.P., "Case of Retroflexion of the Uterus, Progressive Hemiplegia with great loss of Temperature, Replacement of the Uterus, Recovery."

Dr. A. B. Steele, "On the Treatment of Puerperal Eclampsia."

Mr. John Bassett, "Secondary Uterine Hæmorrhage."

Mr. Lawson Tait, "A Case of Bitro-Uterine Pregnancy, Diagnosed and Operated on during Life."

SECTION D.—PUBLIC MEDICINE.

This section was presided over by the Rev. Dr. Haughton.

SECTION E.—PSYCHOLOGY.

President, Dr. Maudsley.

The following papers were read:—

Dr. Browne, 1. "Erysipelatous Encephalitis." 2. "Instruments for measuring the Depth of the Grey Matter of the Brain."

Dr. J. Batty Tuke, "Morbid Specimens and Microscopic Slides demonstrating certain Forms of Cerebral Disease."

Dr. T. S. Clouston, "The Local Distribution of Insanity."

Dr. J. Lockhart Clarke, 1. "A Case of Mania." 2. "Morbid Specimens of Brain Tissue."

Dr. Thompson Dickson, "Microscopical Specimens of Morbid Nerve Tissue."

Dr. W. Wood, "On the Use of Concrete in Asylum Buildings."

Dr. Stanley Haynes, "On the use of Restraint in the Treatment of Mental Disease."

There was of course a dinner and a soirée, besides which the hospitality of our Birmingham brethren was equal to its reputation.

The Report showed as usual a miserable financial condition, in spite of the many promises made.

A great deal of routine business was transacted. The several committees presented reports lauding everyone, and the meeting was throughout pervaded by an atmosphere of mutual admiration amongst the permanent officials.

THE PRESIDENT'S ADDRESS.

Situated at the north-western extremity of the county of Warwick, forming most probably a part of the old forest of Arden, Birmingham is built on the eastern slope of three undulating hills, on the banks of two streams, the Rea and the Tame, and is one of the highest towns in the kingdom. All the approaches are by ascent, excepting that from the west, where the highest point of the borough is reached. This spot, at the top of the Hagley Road, is 617 feet above the sea-level, whilst the lowest point, at Saltley, on the east, is 283 feet. Between these extreme points, the ground-level of St. Philip's Church, in the centre of the town, is 462 feet, and that of King Edward's School, in which we are assembled, is only thirty feet lower. The absence of any dominant hill surmounted by a lofty public building prevents these elevations from being realised at a glance, but the height and the undulations in surface may be inferred from the fact that most of the streets pursue a diagonal course so as to lessen the declivities. The ground is naturally poor, in an agricultural sense, and consists of sand, gravel, and clay. The substratum is of new red sandstone, which passes from the river Tees southward to Birmingham, and thence northward to the Mersey. The southerly and oldest part of the town, running from High Street to Deritend by a deep descent, is the lowest and dampest portion. It is here crossed by the river Rea,

and has much clay in the sub-soil; this clay extends up the valley of the stream to Sparkbrook, and ceases only at Moseley, which has a higher level and a sandy subsoil. From the conformation of surface and the character of the ground, it is clear that Nature has supplied every requisite for surface drainage into the streams, and for the rapid percolation of storm-water through the porous sub-soil: hence floods are rare. In former times, as the late Dr. Darwall told us in the *Medical and Surgical Reporter* of 1828, after heavy storms or unusually wet seasons, Deritend, in the neighbourhood of the Rea, was liable to inundations; but this evil is now, rectified by the strengthening of the banks of the stream, by the interception of the current for manufacturing purposes, and by the erection of bridges. In order to render the drainage of the town more perfect, a system of deep artificial sewers has been designed and nearly completed. By means of these channels all sewage is conveyed to a spot at the extreme east of the borough, three miles from its centre. At this outlet the mains are large in dimensions, are placed five feet above the level of the top-water of the Tame, and have storm-outlets to aid in carrying floods into the river. These sewers, constructed according to the dictates of modern science, are on the gravitating principle, so as to require neither machinery nor steam-power. The levels are so arranged between eleven, the minimum, and forty-two feet, the maximum depth, as to ensure a current that will carry refuse from the most distant part of the borough to the outlet within the space of two hours. This rapid flow is said to prevent decomposition and the generation of foul gases in the sewers; but pedestrians in close weather may complain that unsavoury odours occasionally escape through the ventilators into the roadway, and that some contrivance for ensuring the conveyance of these gases to a higher level, where they would be speedily diluted, oxidised, and diffused by the upper currents of air, would be very acceptable, and must be contributory to health. There is one portion of the borough, the Small Heath district, which is unconnected with this system of drains. It is on the south side, consists of 930 acres of ground, of which 750 are under cultivation, and has a population under 6,000, and has a daily dry weather flow of sewage of 214,000 gallons, which passes into a tributary of the river Cole. The area of the borough, 8,420 acres, when divided between 350,164 inhabitants, the estimate of the last census, gives upwards of 124 superficial square yards to each person, an allowance that probably accounts for our freedom from typhus, as fully as the absence of marshes and bogs explains our immunity from ague. The distribution of this area, however, is not so equal as might be wished for sanitary purposes: the space per head varies in the different wards from 695 square yards in Edgbaston to thirty-one yards in St. Martin's Ward. Seven other wards yield a smaller superficial area than 100 square yards for each inhabitant. The density of population in the central and older parts of the town may be comprehended, but that districts which have been built since the importance of sanitary rules has been known should have been allowed to exceed the limits of health in house accommodation, is only to be attributed to the anomalous position of a corporate body which, whilst endowed with powers to levy rates and govern the town, has no authority to curb the crude and ignorant designs of the building speculator, who, in order to secure a large immediate return for a small outlay, is at liberty to construct a court of scanty surface, approached by a narrow alley, with rows of sheds called houses, built back to back so as to support each other; defying through-ventilation, yielding scanty space for the admission of pure air, and as little for the escape of that which has been exhausted by respiration. From these courts, possessing not a single sanitary attribute, containing open middens of faulty construction, arise fetid exhalations that pollute such air as enters the still enclosure; the leakage from the ash-pits through the soil into the wells from which water is drawn, gives rise at times to an excessive mortality from scarlatina, typhoid, diphtheria, diarrhoea, and other preventible diseases of a like type. Let contagion enter a space thus circumscribed, and the result may be safely predicted. For the tenants of these defective courts, the only airing grounds are the streets, which fortunately present many open spaces in various parts. Well might Dr. Greenhow declare that "more than half our annual mortality results from diseases which prevail with a very great range of difference, in proportion as the sanitary circumstances are bad or good," and that the mortality from preventible disease in certain districts "raises the death-rate of the country 33 per cent. above the death-rate of the

healthiest part." The powers wanted to suppress this evil need not be vexatious. They are required only for the protection of the poor, embrace the simple questions of ventilation, space, and sewage, and might be safely dictated by a health officer, aided by the borough surveyor. Before quitting this part of my subject, I must briefly refer to the disposal of our sewage, of which a large portion has been hitherto discharged into the river Tame. It is easy to accept and adopt an aliterative cry like that of "rainfall to the river, sewage to the soil," and the application of the principle, if possible, would promise an inestimable advantage. The Town Council of Birmingham has attempted to carry out a modification of this scheme, by seeking power to enable them to purchase land for the disposal of the fluid sewage by "intermittent downward filtration," and the conversion of the more solid matters into an element of fertility to the land, instead of danger to its occupants. This intention has been thwarted temporarily by the inconsiderate vote of a small majority of our legislative assembly, but the question cannot be thus summarily settled; it must again and speedily enforce parliamentary attention, and, unless the value of a few acres of land is to be recklessly staked against human life, the convenience of the few must yield to the urgent necessities of the many. Whilst sympathising with the Corporation in their efforts and their defeat on this question, there is one marked and culpable defect in the official appointments of this borough which demands severe animadversion. The imperfections that have been mentioned could not have existed unremedied had there been a well-qualified medical officer of health possessing technical knowledge of hygienic rules; capable of guiding the deliberations of the Council on this subject, and of framing comprehensive plans for the prevention of disease and the promotion of health. Such an officer, rendered independent by an adequate salary, freed from the cares of Medical practice, exclusively devoted to sanitary science, and armed with power to exact information and aid from all the executive officers of the borough, would secure to the inhabitants that skilled care which they have a right to expect, would represent faithfully the views of our Profession, and would be competent to contribute to those discussions between the "associated officers of health" which have materially advanced our knowledge of scientific hygiene. The cost of such a man would be more than compensated by a diminished rate of illness and pauperism, a more steady capacity for labour and a smaller ratio of crime. All of these points materially affect the financial expenditure of the borough. By the Public Health Bill this defect will be remedied, and the town will be placed beyond the reach of amateur legislation, which has too often resulted in unscientific experiments, with a population as the *corps vile* for their trial. A sound, highly educated man should be selected from the members of that Profession which has supplied those philosophical "Privy Council Reports" of the sources of disease and death that have guided our Imperial Government, have formed a magnificent contribution to sanitary science, and have tended to make popular the broad rules of hygienic knowledge. This course, the only proper one, will rescue our corporate body from the humiliation of seeking, as it has done, the gratuitous guidance and opinions of their Medical fellow-citizens, whose special learning has been acquired by devoted labour and technical education, which are estimated in other and ordinary transactions by an equivalent money value. The large surface over which Birmingham is spread, and which has led to its being declared by Mr. Rawlinson "the most openly-built town in the kingdom," contributes materially to its healthiness. Our streets are of fair width, excepting in the old town, in the main thoroughfares of which efforts to approximate them to our present requirements will be obvious to all. The buildings are low, rarely consisting of more than three or four storeys, and therefore offering little obstruction to the currents of air, with which an elevated table-land is sure to be visited. In some thronged business parts, such as High Street and Bull Street, the increasing value of land and the necessities of trade have led to more aspiring erections, but they have not yet reached the height of the Manchester warehouses, or obscured the sky like the buildings in the old part of Edinburgh. The streets are macadamised and cleanly, being kept in good condition after they have been accepted by the Corporation. Recently formed streets in the suburbs are often defective in drainage and fouled by refuse. The danger from this source may be conceived when I mention that 1,000 houses are annually added to the existing number. The climate is dry, having a

smaller rainfall, and one-third more of dry days than are experienced in Lancashire. Four parks, forming admirable breathing spaces and yielding abundant opportunities for rational amusement and exercise, are opened to our people. On the eastern side of the borough, Aston Park, consisting of forty-three acres, has been rescued from the grasp of Building Societies by the combined subscriptions of the people and of the Corporation. The Sattley Park, presented by Sir C. B. Adderley, comprises ten acres. On the west Calthorpe Park, of thirty acres, has been the only recreation ground until lately; but within a few months an estate of fifty acres, called Cannon Hill, ruraly situated, well timbered and watered, with a varied surface, has been presented to the town by Miss Ryland. It is due to this large-hearted lady to say that, by this and other deeds of kindness and humanity, she has shown a noble estimate of the duties of wealth; and a determination to mitigate the trials, ameliorate the condition, and promote the happiness and comfort of the labouring population of this town. Although placed on the outskirts of the borough, none of these parks are so distant from its centre as to overtax the physical powers of an indifferent pedestrian. Few of our manufacturing processes are directly detrimental to health. The entire class of grinders, metal and wood-polishers, and moulders, are exposed to pulmonary irritation from the inhalation of dust, whilst "wet-grinding," as it is called, super-adds damp clothes and wet feet. A few suffer from heat only, as the lacquerers and glass-blowers. The majority of our workpeople, however, are more influenced by constrained positions whilst at work, by defective ventilation in crowded manufactories, and by atmospheric vicissitudes, than by any special risk or danger. For some of these evils remedies have been provided by the employers of labour, but self-will and intractability on the part of the mechanics at times render these precautions useless. The trades of the town are numerous, and the sub-divisions of labour are unusually great; hence, the fluctuations of commerce rarely fall heavily upon the entire class of artisans, and famine is of very rare occurrence. There is no cellar population. As a broad rule, every family has its own dwelling-house, so that excessive overcrowding, with its consequences, is avoided. These circumstances probably explain the favourable records of mortality, which have scarcely varied during the last thirty years, and have been a fraction below 25 per 1,000. A supply of pure water has been called "a natural right," and Professor Gairdner says that "wherever water has become a matter of private sale or barter, there has been a dereliction of duty on the part of the community as represented by the local authorities." It appears to me that the means of cleansing and purifying and lighting should be secured to every dwelling-house. To the poor these adjuncts to health and comfort are necessities to moral and physical well-being. An irreparable mistake was committed here when the local authorities, evading or failing to perceive their proper responsibilities, permitted duties that should have been municipal to escape them, and allowed the control and the profits of the water and gas supplies to pass into the hands of private companies. The acquisition of such properties now would cast a heavy additional burden upon the ratepayers; whilst, as a preliminary to the formation of new competitive and municipal schemes, it would be requisite to prove inadequacy or impurity in the supplies of the existing companies before imperial legislative sanction could be sought or obtained. In 1823, the late Dr. Darwall declared the water-supply of the town to be defective. Drawn from springs and wells, the best water was hard, and contained two or three grains of muriate of lime in the pint. Wells in the vicinity of manufactories were impregnated with copper and tin, so as to be nauseous and sometimes emetic; and the majority of waters near the centre of the town contained nitrates from sewage pollution. For domestic purposes, the inhabitants at that time were chiefly supplied from pumps in Digbeth, which were found by the late Thomas Southall to contain seven grains and a half of the nitrates of lime and potash to the pint. Hence you will probably agree with me, that the time was ripe for any scheme that promised potable water to a thirsting population. The first service of our waterworks company was laid on in 1831, the supply being drawn from the river Tame. Much prejudice existed at first against the water, and this may have been preservative; for in 1832, when cholera ravaged Wolverhampton, Willenhall, Walsall, Bilston, and other places through which the Tame flows, and from which it receives drainage, the water company supplied only a small district of the town, and that chiefly for manufacturing purposes. It is, however, a curious fact that,

although the sewage of many populous places pollutes that stream through its tributaries, such is the purifying power of running water in oxidating and rendering innocuous their refuse, that at Hamstead, some five miles below the last sewage entry into the Tame, fine and healthy trout are frequently taken by the angler. As the advantage of a free and constant water supply became felt, the company obtained additional powers, and wisely excluded rivers that from running near towns may be contaminated by sewage matters. Discarding the Tame, their supplies are now drawn from streams passing through purely agricultural districts (notably from the Sutton Basin) and from Artesian wells bored into the new red sandstone, which promises an abundant supply of pure well-filtered water. It has been roughly estimated that nearly two-thirds of the town are thus supplied, and that the daily consumption amounts to upwards of eight millions of gallons, or between thirty and thirty-five gallons per head. Whatever criticism may be passed upon its purity, the water may be drunk without fear. It is vastly superior to that of the old wells, the aeration of which was so pleasant to the palate as to conceal its impurities. Our borough analyst, Dr. Hill, has declared it to be superior to the standards accepted by the Brussels Congress and by Dr. Parkes. Few things better illustrate the existence of an ebb-tide in the progress of civilisation than the supply of water to large cities. Our popular perception of the necessity of pure water is comparatively recent, but in their day of power the Romans were alive to its importance as affecting health and comfort. The extent and magnificence of their aqueducts for supplying the household wants, the fountains and baths of Rome with water, do not rest on mere historical record. Two of these engineering triumphs are yet in existence and in use, the Aqua Virgo and the Aqua Paolo or Alsietium. Grand in conception, admirable in execution, they pursued their course subterraneously or on arches, according to the levels, and were worthy of the Emperors under whose rule they were constructed. The streams which run near to the town need not be described, as they are unimportant; they all run into the Trent, which joins the Ouse and the Humber, so that our river water reaches the sea on the coast of Yorkshire. The atmosphere of Birmingham will compare, and not unfavourably, with that of other manufacturing cities. We know that it is vitiated in parts by those emanations which must occur in every dense population, and more especially if sanitary supervision be perfunctory and inadequate. One of our greatest evils is the smoke issuing from the tall chimney-stacks of our manufactories, and perceptible for some miles beyond the town. It is curious that, whilst solemn predictions are issued as to the exhaustion of our coal-fields, and the approaching substitution of some other fuel, whilst the press dispenses Jeremiahs on the increasing cost of coal, this wasted carbon is permitted to obscure the sky, to fill the air with fuliginous impurities, and to return to us as smuts for the encouragement of the laundress. No scientific mechanic impressed with the motto "*ex fumo dare lucem*," has yet invented a perfect machine, acceptable to employers of labour and of moderate cost, by which this waste fuel may be utilised without the aid and imperfection of a human stoker. Whilst of late years the town has grown rapidly, and has offered new sources of attraction to the labourer and the merchant-prince of commerce, it has always worn features of interest to the man of science, the politician, and the philanthropist. In archæology we have few attractive remains. The ancient landmarks and monuments described by the learned Hamper and others have disappeared under the requirements of a rapidly increasing population, and a necessarily extended building area. The fine old Elizabethan Hall at Aston is well worth a visit on account of its architectural features and its historical traditions. The residence of Sir Thomas Holte it afforded shelter to Charles I. in October, 1642, whilst on the march from Shrewsbury to relieve Banbury Castle, and before the battle of Edge Hill. Subsequently it was cannonaded by the Parliamentarians, and reduced after a two days' siege. Such slight injuries, however, were inflicted on the building as to raise a smile in these days at the artillery then in use. In the church of St. Martin may still be seen monuments that carry us back to the period of the Normans, whilst our portion of the great Ikenield Road that stretched from Southampton to Tynemouth, recalls to memory the time of the Cæsars and the occupation of the country by the victorious legions of Rome. We cannot compete with those natural attractions that at Plymouth seduced stern devotees of science from their allegiance, but we can show how advancing knowledge influences man's invention, skill, and industry,

and subjects natural and chemical forces to his control; how labour is dignified and intellectual supremacy is asserted by the employment of those potential agents—steam, heat, electricity, and chemical action, which are here made to carry out the most gigantic and most delicate operations. So near are we to the furnaces and smelting works of South Staffordshire, that their vicinity is revealed at night by a glow in the sky from numerous fires. This has been called the "Aurora Borealis of the Black Country," and has been poetically described by Elihu Burritt as "the halo around the brow of swart and patient labour that knows no rest." Having retired with this luminous reflection to repose, instead of awakening to the rippling music of a Devonian tide, you may be rudely disturbed by the steam gong that summons the mechanic to his early labour, or by the mighty throb of the steam-hammer stamping automatically the resisting metal, and impressing it with forms of beauty or utility. It has been well said that this town "is the most remarkable centre of manufacturers of metal in the world." "Whatever metal can do, Birmingham will make it do: from a pin's head to a steam-engine, from a pewter pot to a copper boiler, from a gilt button to a brass bedstead." Certainly the metals, precious and base, are here, by mechanical agencies or manipulative skill, made to assume every shape, from the delicate ornament vying in capillary tracery with gossamer, from the frail threads of wire that bind our island to distant continents and establish inter-communications incredibly rapid, to those monstrous masses of metal which span the chasm or rushing stream and form the iron roads of intercourse and traffic between the busy communities of which this country consists, and by whom its unparalleled commercial prosperity has been achieved. Whilst these triumphs of this midland city proclaim themselves in sonorous utterances, abundant illustrations of more silent forces in use amongst us may be furnished. Here you may witness the chemico-galvanic process of metallic deposit, conceived and perfected by one of our Professional brethren, the late Mr. Wright, and worked by Messrs. Elkington and Mason, who have administered largely to the wants of civilised life. The effects of this invention have been to beautify the commonest material, to decorate our houses and persons, and indirectly to refine our habits and elevate our taste. A reference to this subject suggests the intimate connection that subsists between the various branches of human knowledge and industry. Had not our power of dealing with metal, in moulding, casting, and chasing, progressed, this filmy electro-deposit—which bears the same relation to the material enclosed by it, as does the amber to the fly that it embalms—would scarcely have been devoted to such general uses. So again, had not the study of natural forms been advocated by the appeals of cultivated men, who appreciated the glorious relics of a civilisation that has long passed away, our manufacturers would scarcely have produced those graceful and classical designs, which characterise much of the ornament of the present age, and which may, by further cultivation, enable us hereafter to challenge the productions of the palmiest days of Greece. One noiseless craft to which I would call your attention is the *papier mache* trade, which is almost peculiar to Birmingham. Derived first from India and China, it was introduced here more than a century ago by Mr. Taylor, a large and ingenious employer of labour, for the production of snuff-boxes and trays. So wide is its applicability, that it is now used, not only for knick-knacks, but for the construction of such massive domestic articles as sofas, bedsteads, sideboards, and chairs. The prepared surface of this paper-pulp receives a high polish, and is capable of such complex decoration by mother-of-pearl, artificial gems, gold and painting, as to conceal its texture, and render the material unrecognisable. It has been too much the custom to consider Birmingham as a hive of busy artisans not over-refined; a nest of metal-workers so expert in imitative art, and so little troubled by qualms of conscience, as to be constantly engaged in the production of "lacquered shams and bad halfpence." It is lamentable to see such accusations made in London newspapers whenever our population disagrees in view with a literary Jupiter, or offends the delicate susceptibilities of some writer of political and other "leaders." To such men it is useless to suggest that a community cannot fairly be saddled with the sin of an individual. It is long since Charles Knight, in "The Land we Live In," showed that the wondrous skill with which metals are handled has led to the ingenuity of our artisans being occasionally enlisted by unscrupulous non-residents, who have carefully concealed their designs, and have saddled our too-confiding class of operatives with their sins.

How many works of art, useful and ornamental, that have been accepted as national standards of taste, have sprung from the talent and labour of our workmen, and have been credited to other cities, it is not my duty to inquire. The thought, however, is suggestive in its truth. The commercial position and material prosperity of this town have been due to such men as the late Matthew Robinson Boulton, John Taylor, and others, who possessed the highest views of moral rectitude and honour, and with a keen sense of the wants of mankind, established new methods of administering to them. It may be said of Mr. Boulton—a Birmingham man, and a veritable Meccenas of manufacturers—he was highly educated, that he cultivated science, associated with men of learning, and introduced into trade new applications of mechanical power. Prudent and perceptive, he won his laurels in the stony paths of trial and difficulty. The Soho Works, built by him more than a hundred years ago, then formed the largest manufactory in England. Hence these works—which employed a thousand people—became an object of interest to the whole kingdom. Here, after Boulton had been joined by James Watt, the first perfect steam-engine was made which supplanted water-power, revolutionised commerce and travel, and supplied the world with a new motive force. Here, also, our coinage was beautified and improved; and here Mr. Murdoch, the engineer of the firm, first introduced the illuminating power of gas to this country, which has contributed so much to man's comfort and convenience. The works were built on a barren heath some two miles from the town; by planting and draining, the surrounding land became a park with fine timber and water, worthy of its princely inhabitant. The works stood for many years after their glory had departed. They were visited by strangers from distant lands, and had an interest to our Transatlantic cousins that rivalled the shrine of Shakespeare. This "Mecca to mechanism," as it has been aptly called, is now no more. The building has been pulled down, and its site—like all available land in increasing communities—is advertised as suitable for "villa residences"! Boulton's time was the Augustan era of Birmingham. Taking only the eminent men who constituted the Lunar Society (so called from their meeting when the moon was at its full and would facilitate their travels), it may be said that few towns could boast such an array of remarkable talent and capacity. The names of Boulton, Watt, Withering, Priestley, Galton, Keir, and Berrington are sufficient to prove the assertion; and Mrs. Schimmelpenninck describes each member as being "the centre of intellectual friends" who frequented the meetings, and added to the depth and brilliancy of their discussions. The mention of Sir W. Herschel, Sir Joseph Banks, Dr. Solander, and Dr. Afzelius, as frequent visitors, is a sufficient stamp of their intellectual calibre. In this town also Dr. Roebuck introduced the use of the lead chamber in the production of sulphuric acid as a substitute for the two old methods of burning sulphur under bell-glasses, or distilling sulphate of iron at red heat. By this improvement he rendered the process continuous, increased the power of production, and reduced cost. The value of his discovery may be estimated when it is remembered that sulphuric acid is essential to all the metal trades, and that without it the present gigantic works for the production of alkali and artificial manure could not exist. Whilst ready to welcome and adopt strangers, Birmingham has not always appreciated the genius of her children, but has presented herself at times as a stern step-mother. The populace, whilst thoroughly loyal, orderly, law-abiding, and usually tolerant in spirit, has been betrayed at times by misconception and misguidance, into transitory tumult and violence. The two subjects, Politics and Theology—inseparable in this country—have rarely borne a free discussion without leading to more human passion and unrighteousness than all other sources of difference to which we are exposed. Against this we appear to have no protection. The *odium theologicum*, once fulminated, recognises no genius opposed to its own narrow doctrines, and is antagonistic to that spirit of inquiry which human progress has been promoted and a higher stand-point reached. To this may be ascribed the terrorism which prevailed in 1791, when Priestley, the philosopher, chemist, and scientific inquirer—when Baskerville, the greatest printer that England has produced, the founder of the most perfect type known, whose edition of the Bible is sighed after by bibliographers, whose exquisite productions of the ancient and modern classics, and of Wm. Hunter's work on the Uterus, are considered to be treasures of typographic art—were, with other citizens who did not conform to the views of the mass, persecuted relentlessly by

the destruction of their houses and property, and they themselves narrowly escaped the *auto-da-fe* of a popular, though unreasoning, Inquisition. It is lamentable to think that a reflective and accomplished inquirer, whether right or wrong, was driven by a bigotry and intolerance to seek a home for his later years of life beyond the far Atlantic, and that a type so fine as that of Baskerville, employed by him in the diffusion of the highest knowledge—the divinest revelation vouchsafed to man—should have found its last resting-place in a faubourg of Paris, its first duties in spreading the sophistries of Voltaire. The Medical annals of this town furnish a full list of distinguished men. The philanthropic Dr. Ash, who founded the General Hospital, earned the highest local fame. Failing health caused his removal to London, where he was made a Fellow and Censor of the Royal College of Physicians. Dr. Witherington, his immediate successor, was widely known by his botanical publications. He lies in the parish churchyard of Edgbaston, close to the hall in which he passed many years of life. Dr. Male, highly esteemed as a sound physician and most honourable man, rested his literary fame upon his "Furidical Medicine." To say that Dr. Edward Johnstone was a highly cultivated physician; that his brother John—your president in 1834—was an accomplished scholar, an intimate friend of Dr. Parr, with whom he sympathised in classical lore; and that Dr. James—the president of your last meeting here—won esteem by his acquirements, his courtesy, and his kindness, would be a work of supererogation to the older members of this society. Whilst paying merited honour to our physicians, it is due to the surgeons of the town to state that the literature and practice of our art have been ably represented by those who have preceded us. George Freer, a surgeon to the General Hospital, was the first who successfully applied a ligature to the external iliac artery for the cure of femoral aneurism, as suggested by Abernethy. From the study of this and other cognate cases, his pupil, the late Mr. Joseph Hodgson, probably derived the bias that led to that admirable memoir, "On the Diseases of Arteries and Veins," which secured the Jacksonian prize of the Royal College of Surgeons, became a surgical authority, and secured for him that character for sagacity and judgment that he subsequently enjoyed. More recent Jacksonian prizemen may be named. My colleague, Mr. Crompton, earned this distinction by an essay on diseases of the tongue; the late Frederick Ryland by a valuable monograph on the throat and larynx; and Mr. John Clay by a treatise on ovarian disease. It is to be regretted that the essays of Mr. Crompton and Mr. Clay have remained unpublished. To extend the list would—if I have not already earned the rebuke—be tedious. I will content myself, therefore, with saying that our profession yet numbers members who will not suffer the reputation of Birmingham surgeons to decline from its achieved position. Having referred thus briefly to the older officers, who were necessarily connected with the general hospital as the only large Medical charity in existence, I must now be permitted to say that examples nobly set have been zealously followed, and that a variety of institutions, secondary perhaps in scope, but paramount in popular interest and sympathy, have been established amongst us. The Queen's Hospital, founded by Wm. Sands Cox, in connection with the Queen's College (which it was his dearest object to convert into a great Midland University), graced by the favour of Royalty, and approaching in magnitude to its elder sister, competes with it for support. The General Dispensary; the Midland Eye Hospital, founded by Dr. De Lys and Mr. Hodgson; the Hospital for Sick Children, so eloquently advocated by Dr. Heslop; and a special Hospital (recently established) for women—appeal, and not in vain, to the sympathy of contributors. A Sanatorium is in course of erection, designed to furnish ample space, the most perfect hygienic arrangements, and life-giving air from the breezes that play over the hills of Blooms Grove Lickey. This will form an adjunct to all the Medical charities, and will be suited to invigorate frames that have been exhausted by disease, and are unfitted to encounter the evil influences of a close residence in a polluted atmosphere. Under the auspices of my friends Dr. Fletcher and Mr. Kimbell, an institution has been founded at Knowle for the treatment of imbecile children upon the principle of the Earlswood Asylum. From the adaptation of a cottage to the wants of a few inmates, they have so completely established the benefits that may be conferred upon these piteous claimants for human care and benevolence, that the sympathy and co-operation of the wealthy have been secured, and a noble building has been commenced, which promises to administer adequately to our local necessi-

ties. With regard to the establishment in which we are assembled, it is, architecturally and educationally, one of the brightest ornaments of the town. Originating in the wise consent of a youthful king to a petition from the inhabitants of Birmingham, a small annual grant, devoted by pious men to the Convent of the Holy Cross, after the dissolution of these monastic institutions by Henry VIII., was granted for educational purposes, and formed an endowment for this school. The value of the lands thus bestowed has increased a thousand-fold, and the income has in course of time become regal. Regarded as a school for imparting a classical and general knowledge, it has amply fulfilled the intentions of the founder by securing to the young a liberal, scholarly, and often an University education. Its past history is full of bright associations; and whatever modifications in its course of instruction may be needed to meet the wants of the present age, it has deserved well of the past generations. You will share with me in an expression of deep regret that personal illness has prevented our associate Dr. Fleming from delivering the address in medicine, and from taking that prominent part in this meeting which he was invited to assume by your Council, and for which his literary and practical requirements and his known accuracy so peculiarly fitted him. We must all lament that the voice which advocated this town as your place of annual meeting will be heard no more. The energy and fervour of Mr. Clayton's manner, his singular conversance with the affairs of the Association, and his judicious advice in its management, will be missed by the active members; whilst we, his intimate fellow-workers, regret the loss of one possessed of great perceptive and executive ability, and endeared to us by many estimable personal characteristics. Other hands, however, will be extended in friendship and brotherhood; other voices will proclaim our hearty appreciation of your visit. As the representative of the Birmingham and Midland Counties Branch of the Association, and in the name of the whole Profession of the district, I say to all our visitors, welcome, welcome, thrice welcome.

REGISTERED FOR TRANSMISSION ABROAD.

THE

MEDICAL PRESS AND CIRCULAR

is published simultaneously in London, Dublin, and Edinburgh, every Wednesday morning. Price 6d. Post free, 5½d.

POST FREE TO ANNUAL SUBSCRIBERS £1 2 6
 " IF PAID IN ADVANCE 1 0 0

* Post-office Orders and Cheques to be drawn in favour of—
 A. A. TINDALL, 20, King William Street, Strand, London, W.C.
 A. H. JACOB, Molesworth Hall, Molesworth Street, Dublin.
 MACLAUGHAN and STEWART, South Bridge, Edinburgh.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIÈRE, Publishers to the Académie de Médecine, Paris—post free in advance £1 6s. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLMER and ROGERS; Baltimore, by Messrs. KELLY and PIET; Philadelphia, by Messrs. LIPPINCOTT and Co., and Dr. BUTLER, post free in advance, £1 6s., or about six and a-half dollars; or direct from the Offices in this country for the same amount, by the new Post-office Order system.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 14, 1872.

SPECIALISM.

DR. WILKS, who is always listened to with attention, has lifted up his voice against *specialism*. He is not one

to lose force by adopting feeble expressions, and for this, as a rule, we may be grateful. But we doubt very much whether he has spoken at Birmingham with his usual sound common sense. Perhaps the holiday character of the meeting made him feel it was no scientific assembly at all, and that his hearers only wanted a few smart jokes. This is well enough, but even the public cannot fail to be shocked at his sneer at asylums for "jabbering idiots." Much that he said against specialties may be equally used as arguments in their favour. He obtained his attack by confessing that specialism was a very natural result of the feeling which all persons had to gain relief for their individual troubles, without thinking of the deeper question of the cause of them, and asking, was the public right in its demand, and the Profession in submitting to it? He declared there could only be one answer, and the idea of chopping up the body into separate parts must be strongly deprecated. It might be asked, has not scientific advance encouraged specialism. He should say decidedly not. Specialism was more rife in ignorant times, but of late the fondness for specialties had been waning, and a larger view of the practice of medicine founded on a more scientific basis was taking its place with the progress in their science and art, and thus meddling with particular organs and symptoms had decreased. And yet Dr. Wilks went on to show where specialties were useful by declaring that one of the few specialties where a long and extended experience enabled the Professor to gain a larger knowledge than the mass of Medical men could possess was in the case of mental disease; but this, with astounding hardihood, he said, was one of the few least patronised by the public. At least, from his own observation, it had seemed that when a man's mind was going wrong the last person whose aid he sought was the mad doctor—(laughter). Even the division into medicine and surgery had its evils, and thus he was convinced that the best advisers for the people at large were the general practitioners. But not only did the Profession suffer in its true scientific dignity by its being divided, and those who sought advice often meet with disaster; not only this, but the poorer portion of the community suffered from the diversion of benevolence into wrong channels. This was Dr. Wilks's trump card, and he pleaded for the general hospitals in a way that, as remarked by many, is not likely to do them much good; for he urged that it was a standing disgrace to England and especially to London, that so little was contributed towards the maintenance of general hospitals. The public would not subscribe their guineas for so mean an object as the cure of an inflammation of the lungs, an erysipelas, or a broken leg, but chose rather to give their hundreds and thousands to some special institution pleasing to their fancy. Sentiment often entirely ruled, and thus the abject poor, with their vulgar wants, were neglected, whilst any amount of money could be raised to expend on a beautiful house and grounds for the care of hopeless "jabbering" idiots. Then he went on to admit a trifle on the other side, for, said he, only one thing could be said on the other side—that it gave those engaged in the practice of one department greater facility in manipulation and the use of remedies.

Now what could be with the public, if not with the Profession, a more forcible argument? The sick man is only too glad to avail himself of skill in "manipulation and the use of remedies." One word more and we have

done. Dr. Wilks did an injustice to many when he assumed that the specialist knew nothing but his specialty. The only good specialist—the only safe one is, he who has a wide knowledge of every branch of his profession.

**REFORM IN THE MEDICAL CORPS,
AND
SANITARY SERVICE OF THE ARMY IN
PORTUGAL.**

ORGANISATION—DISTRIBUTION—AND PAY.

ART. 1.—The Sanitary Corps of the army is composed of one Surgeon-in-Chief of the army with rank of colonel.

Two Surgeons of Division with rank of lieutenant-colonels.

Six Surgeons of Brigade, rank of majors. Two Graduated Surgeons of Brigade, Directors of Hospitals.

The Surgeons Major (Staff-Surgeons), with the rank of captain, as many as are necessary for the different corps of the army. Depot of troops, Military College, Military Invalid Hospital, Sanitary department at the War Office and at the head-quarters of the Commander-in-chief of the army, first class military stations, and army arsenal. The Assistant-Surgeons, with rank of lieutenants for the same corps and depots of the Army Invalid Hospital, and resident surgeons of the Lisbon and Porto Hospitals.

Three pharmacutists, one assistant pharmacutist.

The Sanitary Company is composed of:—One captain, one lieutenant, one sub-lieutenant (ensign), three first sergeants, five second sergeants, four furiers, twenty corporals, ten auspeçadas, sixty soldiers.

§ During extraordinary circumstances, the Sanitary Corps of the army may be increased with a number of Medical men if required.

The above also applies to the Sanitary Company.

ART. 2.—The direction of the Medical corps and the Sanitary Service of the army, will be composed of two departments, one annexed to the Minister of War, and the other to the commander-in-chief of the army.

The Surgeon-in-Chief of the army, has the direction of the Sanitary department at the War Office, with all the attributes formerly possessed by the extinct "Sanitary Board of the Army."

§ I. In order to simplify the direction of business in the Sanitary Department, the Surgeon-in-Chief will be entrusted with the service at the War Department, and the commander-in-chief of the army.

§ II. Two Staff-Surgeons will each be attached to these two departments, and will assist the Surgeon-in-Chief in the work assigned by him.

ART. 3.—The two Surgeons of division will take the place of the old army Surgeons, and of the Delegates of the Army Board of Health.

§ I. In time of war the Surgeons of division will be the chief Sanitary officers of the great division of operations.

ART. 4.—The six Brigade Surgeons have to fulfil the same functions as the Surgeons of Division in the 7th, 5th, 2nd, 4th, 6th, and 8th, military divisions.

§ Each brigade in time of war will have for Sanitary Chief, one of the Brigade Surgeons, who in time of peace is occupied in the military divisions.

ART. 5.—The division and Brigade Surgeons have to

reside near the general head-quarters of their respective military divisions, or at the seat of the United Regimental Hospitals.

ART. 6.—The two Graduated Brigade Surgeons, directors of hospitals, and those of the Permanent Hospitals of Lisbon and Porto.

§ 1. The directors of the Permanent Military Hospitals receive pay corresponding to that of the Brigade Surgeons, and in case these should be impeded in their duties, the pay will go to the surgeon appointed in their place.

ART. 7.—The appointments of division and Brigade Surgeons, as also those of Surgeons Directors of the hospitals of Lisbon and Porto will be as much as possible according to priority in the order and category of the situations they have hitherto occupied.

ART. 8.—The staff and assistant-surgeons will be appointed according to the conveniences of the Service.

ART. 9.—The surgeons who, owing to their state of health, or advanced age, are not fit to serve in the corps, will be chosen to serve in the military college, military invalid hospital, fortresses, and military arsenal.

ART. 10.—Two Assistant-Surgeons. Internes of Hospitals residing in the permanent hospitals of Lisbon and Porto have to do the work assigned to them.

ART. 11.—The three pharmacutists are designated as follows:—One to the general depôt of medicines, and one to each of the permanent hospitals of Lisbon and Porto.

The Assistant-Pharmacutist will remain at the general depot of medicines.

THE SANITARY COMPANY.

ART. 12.—The sanitary company, besides the officers, is composed of the *employés* of lower grade, belonging to the permanent military hospitals, and the regimental hospitals united.

ART. 13.—The men which belong to the health company are immediately under the orders of the Surgeon-in-Chief of the army, and those in hospitals receive orders from the directors of said hospitals. The captain and subalterns have charge of the discipline and the execution of all military laws.

ART. 14.—A section of the sanitary company will be detached to Porto, commanded by a subaltern from this section; part will do duty in the permanent hospital at Porto, and the others will serve in the regimental hospital at "Chanes."

ART. 15.—The officers of the sanitary company will be selected among the inferior officers of the army who cannot be despatched to the regular army, but who possess the necessary requirements of morality, zeal, and aptitude in writing and accounts.

§ These officers have a right to promotion in the ranks of the company.

ART. 16.—The three first sergeants are destined to the two permanent hospitals, one to each, and the third to the company's barracks; they have to look after the accounts of these establishments.

ART. 17.—The second sergeants are: two as assistant amanuenses of the permanent hospital at Lisbon, one for that of Porto, and two as first amanuenses in the united regimental hospitals of "Elvas" and "Chanes."

ART. 18.—The four furiers are the buyers and keepers of the two permanent military hospitals, and of the two united regimental hospitals.

ART. 19.—The corporals are distributed, as is thought

most convenient by the Surgeon-in-Chief, they are intended for nurses, first cooks, and porters of the permanent hospitals, and as nurses and cooks at the regimental hospitals united.

ART. 20.—The *auspeçadas* are assistant nurses, assistant cooks, and orderlies at the two permanent hospitals.

ART. 21.—The soldiers are the servants in hospital.

ART. 22.—No soldier belonging to the sanitary company can be removed from his situation, or from the occupation allotted to him.

ART. 23.—For the organisation of this "company" are preferred:—1. The soldiers actually employed at the regimental hospitals, supposing them fit for this service. 2. Soldiers who, during their military service, have been wounded or maimed in such a way as to incapacitate them from serving in the ranks, but not so in hospital. 3. Civilians who may wish to enlist.

ART. 24.—The choice of individuals who may wish to enlist in this service will be made according to his abilities for the position to occupy in hospital; all must know how to read, write, and do accounts.

ART. 25.—None of these *employés* can serve for less than eight years after enlisting, unless disabled in such a way as to render them useless; this must be judged by the Medical Council.

ART. 26.—The soldiers belonging to the health company who have served the time mentioned in Art. 25, and wish to engage for four years more, supposing they are fit for the duties, will receive an extra sum of 20 Reis (One Penny) per diem.

ART. 27.—All the *employés* of the health company will enjoy the same privileges afforded to the soldiers of the battalion of engineers with whom they rank; receiving besides an allowance, as marked in the table annexed to this decree, when they are employed in the hospital or ambulances.

ART. 28.—The inspectors of reviews will verify monthly the situations and pay of these *employés* in the different localities they may be in.

ART. 29.—When the *employés* of the "Health Company" have to enter the hospital on the sick list, besides losing their extra allowance, a deduction will be made from their pay, equivalent to that made to infantry soldiers of the same rank in the army.

ART. 30.—The punishments the *employés* of the Health Company have incurred for crimes committed in the service of hospitals or ambulances will be designated by the general regulations of the sanitary service. When they become incorrigible they will have to finish their time of service in the ranks, and in case they should have completed their time of service, they will be dismissed. Should the offence be a case for Council of War they will have to go through their trial.

ART. 31.—The Health Company will supply the buildings necessary for hospitals, which by Art. 41, Sec. 1, may be organised.

ART. 32.—Men from the Army Corps will only be employed in the permanent and regimental hospitals, in cases of great necessity, in that case they will receive the pay according to their rank, and the allowance marked in the table.

ART. 33.—In time of war the Health Company (in accordance according to the dispositions of Art. 1, Sec 1) will supply the necessary detachments for the great reserves of the division and brigade surgeons.

ART. 34.—To the soldiers admitted (by effect of Art. 1, Sec. 1) Government may exonerate them of their duty when it considers it opportune.

SANITARY CONSULTING COMMITTEE OF THE ARMY.

ART. 35.—The sanitary consulting committee of the army organised in Lisbon, will be composed of the surgeon of division of the first military division, the director of the military hospital at Lisbon, of the senior staff-surgeon of the troops garrisoned at Lisbon.

§ I.—This committee will have to attend only to work ordered by the Minister of War, or to subjects on which the Surgeon-in-Chief may consult them.

ADMISSION—DISMISSAL—PROMOTION—RECOMPENSE.

ART. 36.—The admission into the sanitary corps, for military surgeons, can only be effected by the assistant surgeons.

ART. 37.—No Medical man can be admitted to the rank of assistant surgeon without presenting, besides the documents exacted by the existing regulations, a title of entire approval in one of the Academies of Medicine at Coimbra, Lisbon, or Porto, or of a foreign university legalised in Portugal, and the person being a Portuguese, or a naturalised subject.

ART. 38.—The vacancies of assistant surgeons will be filled by a *concours* of scientific documents, being preferred those who, in equality of circumstances, have had a longer time of practice, and are considered more robust for the service.

ART. 39.—It will be a condition for all Medical men who may wish to enter the service, that they cannot obtain their exoneration before they have completed six years' service, except under extraordinary circumstances.

ART. 40.—The promotion to Surgeon-in-Chief of the Army cannot fall on any Medical man not a military surgeon.

ART. 41.—The order of promotion for all military surgeons will be usually by seniority; though for the promotion of staff surgeon to brigade surgeon, the authorities may prefer one who has recognised scientific merit, or extraordinary services, united to remarkable zeal and intelligence in the practical work of hospitals.

ART. 42.—The Surgeon-in-Chief of the Army will recommend to Government those surgeons who, during the exercise of their professional duties, have rendered themselves worthy of honourable distinction.

(To be continued.)

Notes on Current Topics.

Choked with a Bean.

A FATAL occurrence has taken place at Puddletown, Dorset. Whilst Mr. R. Genge, a well-known agriculturist, was at dinner, partaking of some broad beans, one of them stuck in his windpipe. A violent fit of coughing followed, and in a very short time the unfortunate gentleman died. The deceased was 82 years of age, and was for a very lengthened period one of the foremost agriculturists in the South of England. This illustrates very forcibly the lecture that lately appeared in our columns by Dr. Stannus Hughes.

The Medical Department of the Turkish Army.

ACCORDING to the *Annales de la Société de Médecine d'Anvers*, the Army Medical Department of the Turkish Army is directed by a Board of three inspectors, three deputy-inspectors-general, and two surgeons-major as secretaries. All army surgeons pass through the Imperial School of Medicine; they are then employed in military hospitals as assistant-surgeons with the relative rank of captain; at the end of two years they undergo an examination for advancement, and such as pass successfully are appointed to duty in military sanitary establishments, where they remain for three more, after which they are eligible for promotion, as vacancies occur, to the grade of surgeon, 1st class, with the rank of major. The rule for advancement is that one-third of the steps are given by selection and two-thirds by seniority. In no other army, except that of England, is the pay of the Medical Department so high as in that of the Ottoman Empire.

Ligature of External Iliac.

ON the 23rd ult. Mr. J. D. Hill ligatured the external iliac artery for aneurism of the femoral immediately below Poupart's ligament. The patient passed a good night and is progressing favourably, although the temperature of the extremity fell several degrees (to 89 in the popliteal space; temperature in the axilla being 97°) a few minutes after the operation. In eight hours after its natural standard became restored.

Glass Plates for Dissecting Tables.

A SUBSTANCE on which to lay the cadaver that would not be liable to absorb, corrode, or stain, like wood, zinc, or marble, has long been a desideratum with students of practical anatomy. This, the *Pacific Medical Journal* observes, has been obtained at the Medical College of the Pacific, where Professor Bentley has provided tables with glass tops. Each table consists of a single slab of glass, three-fourths of an inch in thickness, two feet four inches in width, by seven feet in length, laid in moulding plaster. They possess all the properties of neatness, durability, and even elegance.

Death-rate in the United States and Europe.

THE *Philadelphia Medical Reporter* notes the supposed fact, that the death-rate in Europe is nearly double what it is in the United States, averaging yearly one out of every forty-three inhabitants, while here it is only one out of every eight-one. Of the leading countries of Europe, France leads in its mortality, the average being one death to thirty-two people; and England appears to be the healthiest, the deaths being one to every forty-six. In the United States there is a wide range of difference. In Arkansas, for instance, the annual deaths are one to every forty-nine inhabitants, while in Oregon, the rate is only one to every two hundred and nine. It appears that the North-western States average the healthiest, and the Gulf States the sickliest. Perhaps all these astounding figures are, after all, only an illustration of the danger of arguing from a narrow statistical standpoint. We rather think it is the system of death registration in America which is in fault, and lets slip half the mortality.

A Novel Application of the Electric Cautery.

A VERY peculiar and apparently visionary application of the electric cautery has recently been patented in America. The originality of the special application will strike most readers. The patent in question is for the utilising of this principle for the purpose of cutting wood. Dr. Robinson, the patentee, was led to this novel application of electricity by observing the facility with which a platinum wire, when raised to a white heat, effected the removal of tumours. He anticipates that by means of this invention, which requires only a simple quantity battery, trees will be felled and divided into logs, and other operations of a similar nature performed. It is to be presumed that Dr. Robinson has cut sticks with his electric wire before he went to the expense of a patent; nevertheless, the announcement of such a speculation reads more like a satire on Yankee characteristics than a sober commercial suggestion.

Journalistic Medical Amenities in America.

WE clip the following elegant extract from the *Cincinnati Lancet*:—Prof. — takes it hardly that we printed with comments the exposure of the *Lancet and Observer* of his attempt to perpetrate a little fraud upon the Profession and community, as to the real number of students in attendance upon his lectures, and, in consequence, has discontinued his subscription to the *News*. A claim against him for six months' subscription will be sold very cheap by applying at this office.

Cholera in India.

CHOLERA continues to prevail in the districts of the North-Western Provinces. As compared with the numbers recently given, these figures indicate a considerable abatement, and it is interesting to observe from the daily series that this abatement has been simultaneous and progressive.

Dr. Fairweather says, in the *Punjab Gazette*, that during the month (April, 1872) cholera, in an epidemic form, made its appearance in the province; and deaths from small-pox and bowel complaints show their usual increase in numbers at this season; but, notwithstanding this, the total deaths from all causes are rather under those for March, and very much lower than for April, 1871. Cholera seems to have had two starting-points in its progress through the country. One line taken by it followed exactly the road along which a body of pilgrims travelled on their way homeward through the Punjab from the Hurdwar fair. The other starting-point was apparently a fair held in the southern part of the Umballa district, on the 6th of April. The disease seemed at first to radiate from this, and then to take its course through the Kurnaul district.

Cholera.

SOME isolated cases have occurred in Berlin, the filthy state of which gives rise to uneasiness. There is also great distress for want of house room in the capital of the new German empire. Thousands of families are lodged in mere shanties. What will be their condition in winter is a serious problem, and if cholera should become epidemic there the mortality will probably be on a fearful scale.

Cyanosis from Nitrate of Silver Removed by Iodide of Potassium.

DR. YANDELL, Professor of Materia Medica in the University of Louisville, says:—

According to most authorities the stain resulting from the internal use of nitrate of silver is permanent, and not amenable to treatment. The discoloration first begins about the gums and fauces. It has been found in the coats of the intestines and eyes. It may appear several months after cessation of the use of the medicine, and exposure to the sun seems to predispose to its development.

The two cases which have suggested this report are similar in many respects. Both were young merchants, and both had been treated unsuccessfully for epilepsy by nitrate of silver in their youth. Both contracted syphilis, and for tertiary symptoms got iodide of potassium. This drug was given in from ten to sixty grain doses, thrice daily, for a number of months, in connection with ferruginous or bitter tonics. In both cases the fading of the stains was gradual. In the first case there is a faint trace of discoloration remaining, though it is scarcely perceptible. In the second, which was much the darker of the two, there is not a shadow of the disfigurement. It may be well to state that both patients were treated by the moist mercurial vapour bath during much of the time that they were using the iodide of potassium, and the abundant diaphoresis may have assisted the action of the iodide.

Charity.

SOME time since we congratulated the Charity Organisation Society on its having directed public attention to the absurd and even cruel system of what are called, by an abuse of language, "charitable elections." The *Times* has lately given evidence that the subject has not been forgotten, and that canvassing for election to the benefits of a charity is likely to share an unenviable notoriety with the system of canvassing for signatures to petitions. The *Globe* says, truly enough, it is simply an ingenious device for confining the advantages of charitable institutions in which election by vote prevails to those who least need them—to those, that is to say, who have the most numerous, the most influential, the most energetic, and often the most wealthy friends. Those who are friendless, or whose friends have no friends, stand the very smallest chances in a hotly-contested election, unless their cases exhibit exceptional elements of "sensation." "Charitable" institutions so administered are necessarily under the sway of those who are the least scrupulous in getting up "cases." Minute investigation of every claim is the only sound principle, and at present this seems to be almost universally ignored. It does not do to trust too much to the zeal or accuracy of a patroness in favour of her *protégé*. The fact that there is no patron or patroness in any given case should logically be its best recommendation. It is to be hoped the "Charitable Organisation Society" will not neglect to keep the subject before the minds of those who wish to be just as well as generous.

THE rinderpest has appeared at Edinburgh and Leith. The infected cattle came from Denmark and Iceland. Combined with rinderpest is the foot-and-mouth disease, which seems to be of a peculiarly virulent character, five of the infected animals having died.

Dengue.

THIS disease has spread far and wide in India. It has prevailed very extensively in Burmah, and has been reported to exist in many places in the Bombay and Madras Presidencies.

Is Suicide a sign of Insanity?

In the Superior Court at Baltimore, a verdict has been rendered against the Germania Life Insurance Company, of New York, for 2,000 dollars, the amount of a policy on the life of a man who committed suicide. It was held the company was liable if the jury found the deceased had killed himself in a fit of insanity.

SMALL-POX is reported to have broken out at Linderford, in Dean Forest, in a virulent form.

THE Royal College of Chemistry and Royal School of Mines will shortly be removed to South Kensington.

THE Berlin authorities have issued an order prohibiting the importation of Russian cattle along the whole of the Russo-German frontier.

AT Edinburgh at the close of the graduation ceremony on the 1st inst., a marble bust of the late Professor Syme was presented to the University.

THE mortality in London and twenty other large towns has risen to the rate of 27 deaths annually to every 1,000 of the estimated population.

PROFESSOR LEWIS SAYRE, of America, has been made a Knight of the Royal Order of the Wasa by the King of Sweden, in consideration of his services to surgery in that country.

Two children were accidentally poisoned at Hounslow last week, but no evidence was adduced as to how the poison got into their possession—the professors of chemistry at University College stating that it could not be purchased at a chemist's shop.

A MELANCHOLY accident occurred at Kilkee, co. Clare, on Friday last. Dr. F. W. Furnell, in practice at Castleconnell, was bathing at Kilkee, when a strong current carried him out, and before aid arrived the poor fellow had sunk. He contributed to this journal in 1869 a paper entitled "A new Method of Extension in Fractures of the Femur and in Coxalgia."

THE Emperor of Germany has issued the following ordinance:—

"From trusty representations made to us, we command—as a modification of § 7 of 'The Instructions for the Sanitary Service of the Army in the Field, of 29th April, 1860'—that in future the assistant sick bearers of the troops shall wear on the left upper arm a red band, instead of the white band with a red cross. The War Ministry will carry out the further details of this command.

(Signed)

"WILLIAM.

"Berlin, 6th June, 1872."

"V. ROON.

MADRID is now included in the list of foreign cities for which the Registrar-General is enabled to publish the death-rates in his Weekly Return.

THE late Dr. Oak, of Blackheath, bequeathed his residuary estate, amounting to over £25,000, to the following charities in equal proportion:—The Royal Kent Dispensary, Greenwich; the Seamen's Hospital, Greenwich; the Convalescent Hospital, Walton; the Charing-cross Hospital; the Children's Hospital, Great Ormond Street; the Infant Orphan Asylum; the Royal Medical Benevolent College, Epsom; the Royal Free Hospital; the City Orthopædic Hospital; the Asylum for Idiots; and the Royal Westminster Ophthalmic Hospital. Dr. Carr is the surviving and sole executor.

THE *Canada Medical Journal*, which has for eight years been continued, closes its existence with its last number. The publishers state that this has been brought about by personal differences between the editors. The publishers of the *Canada Medical Journal* considered it advisable to stand aloof from all party feeling; they therefore intimated to the editors their determination to stop the publication, leaving them to resuscitate a new work or works, which will stand or fall by their own merits. *Per contra* the late editors have issued this month the first number of the *Canada Medical and Surgical Journal*. In their address to the Profession they say—"A change has taken place in the *Canada Medical Journal*, inasmuch as the editors determined to separate, because of reasons personal to themselves, the details of which would be uninteresting to our subscribers."

VARIOUS expedients have been had recourse to in order to neutralise the vapour of mercury, with which it is now well known every part of the atmosphere in rooms and workshops where operations requiring mercury are conducted is saturated. In even the best ventilated establishments for silvering glass, the skin, hair, beard, and clothes of the workmen are thoroughly impregnated with these invisible fumes. The *Society of Arts Journal* observes that to neutralise the vapour of mercury, sulphur vapours have been proposed, and, to some extent, used, the two vapours combining, and forming a third innocuous compound. As experiments conducted with these vapours have proved fatal when applied to some of the lower animals, it is now proposed to substitute chlorine for the sulphur formerly used. The most convenient way to apply this element is to sprinkle chloride of lime over the floor of the room infected, when the chlorine will immediately combine with the mercury, forming sub-chloride of mercury, or calomel. It is believed that the very small quantity that would be formed would have no ill effects on the lungs of those who breathed an atmosphere containing such an amount of mercuric chloride, but experience will be required to decide this point.

THE *Globe* relates the case of a young man who was imprisoned at the Toombs, New York, and effected his escape in an ingenious manner. He dropped some croton oil on his face, and, all the appearances of small-pox supervening, was hastily removed to the hospital, where he speedily effected his own cure by walking out of bed and getting

clear away. The force of his example was such that an epidemic of small-pox broke out in the Toombes, four prisoners in particular presenting a most distressing appearance, from a too lavish use of croton oil. The gaolers were not, however, to be twice taken in by the same device, and the small-pox patients are being treated in their respective cells. Complications of a serious character are not unlikely to arise out of the incident. Just as in England people found dying in the streets are occasionally treated for drunkenness because it is on the police record that drunken people have not unfrequently been discovered lying insensible in the streets, so prisoners in the Toombs may be treated for croton oil when they are really suffering from an attack of small-pox. Perhaps the simplest way to get out of the difficulty would be to place croton oil out of the reach of the prisoners, a course which it is somewhat surprising to know has not hitherto been the practice in this prison.

Special Report

ON

DISEASES OF THE THROAT.

Edited for the "MEDICAL PRESS AND CIRCULAR."

BY PROSSER JAMES, M.D., M.R.C.P.,

Physician to the Hospital for Diseases of the Throat and to the North London Consumption Hospital; Lecturer on Materia Medica and Therapeutics at the London Hospital.

I.—(continued.)

THAT the mode of supporting the reflector is of little consequence becomes more manifest when we remember that reflection can be dispensed with altogether. As already stated, we can practise laryngoscopy by means of direct light alone. If the laryngeal mirror be properly held a beam of light, from any source, falling upon it is sufficient to furnish an image of the larynx. The difficulty is for the observer to look at the mirror without intercepting the rays of light by his own head. This is why it is easier to sit before a looking-glass and examine one's own larynx by direct light. For his purpose the solar rays may be employed when obtainable, but in all cases artificial light is more manageable. The light of an ordinary moderator lamp is sufficient for all practical purposes. In fact, it is with such a light that some of the most valuable discoveries have been made. Where gas is laid on, a good argand burner is most convenient. The light from either of these may be increased by an ordinary metal reflector placed behind; or in place of the ordinary glass chimney a metal one, with an aperture on one side, will not only increase the light at the operator's disposal, but prevent its diffusion through the room, and thus obviously afford a clearer view of the image. Further, if a plano-convex lens be fitted into the aperture of such a chimney, it constitutes at once a simple and efficient light concentrator. This mode has been adopted by many laryngoscopists for obtaining a good light for ordinary use with a reflector.

In my early experiments with direct light I employed a small lamp with a single lens on one side, and a reflector at the back—a lantern in fact, such as that used by policemen, and sometimes for railway signals. Dr. Brunton's aural lamp is an improvement on this. Tobold's apparatus, which contains three lenses adjusted in a tube, may be also used for experiments with direct light, and it is now made much more portable than formerly. A good lens attached to a pair of spring forceps that will clasp any lamp, serves also as a simple laryngoscope for the use of direct light. Such an instrument is sold as Dr. Johnson's.

Dr. Fauvel, of Paris, has improved upon this by devising a very simple and portable laryngoscope, the use of which is shown in the annexed engraving (Fig. 8).

FIG. 8.

This instrument can be used in any position. The illumination is obtained by direct light, passing from the lamp through the lens A. A tongue-clasp is also attached, but this is not often required. The little lamp is very useful for examining a patient in the recumbent position; but this can be dispensed with, and the Fauvel lens used with any lamp, thus combining the advantages of this apparatus with those of Dr. Johnson's.

The little plane mirror (c) above the lens may be placed at such an angle as to let the patient see his own larynx. This mode may therefore be used for demonstration.

I have tried to utilise the magnesium light for laryngoscopy, but it is very unmanageable. I have for a long time employed the oxyhydrogen lamp, which furnishes a good light equally available for use directly or by reflection. At the Hospital for Diseases of the Throat there is a very good lamp of this kind, which is of great use for demonstrations, the direct rays being always employed. It is too large for the private consulting room, but for hospital use is of great value.

But the purest and brightest artificial light of all is the electric. The difficulty of employing it is that so few electric lamps are simple in construction and therefore easily managed. Mr. Browning has dispensed with all clockwork in his electric lamp, but in addition to its cost, which is considerable, it requires a very powerful battery—about

forty large cells,—and that in its turn demands much attention.

For ordinary use, then, we are driven to the conclusion that gas is the most convenient source of light, and the brilliancy of this can always be increased by burning with it a small proportion of oxygen. A small apparatus for this purpose can easily be affixed to any burner.

SCOTLAND.

THE LADY MEDICAL STUDENTS AT EDINBURGH.

THE interlocutor issued by Lord Gifford in the action raised by Miss Jex Blake and others against the Senatus and Chancellor of the University is favourable to the ladies. His lordship is of opinion that the defenders have failed to prove that the University is restricted to male students, that the regulations for the instruction of women approved of in 1869, and that after completing the prescribed studies in accordance with those regulations, they are entitled to proceed to examination for degrees. In a note he says that, while unable to compel the Senatus to provide suitable instruction for the lady students, he trusts such provision will soon be made. It is doubtful whether the attainment of this object will be advanced if means such as those referred to in the following note, addressed to a local paper, be employed.

United College, St. Andrews,
6th August, 1872.

SIR,—It now appears that, when Sir Robert Anstruther gave notice of a motion to withhold from the Edinburgh Medical professors their parliamentary salaries, it was because they had not acted to his mind regarding the Medical education of women; and we are further informed that in case they do not comply with his behests Mr. Duncan M'Laren will next year cordially support a similar essay.

This needs no comment. My only purpose in referring to it is to say that, with a hearty sympathy for those who would remove from their sex the disabilities to which it has been so long subject, I have yet had too frequent reason to regret the means employed by some who have sought to help towards that end; and this more especially on account of their possible influence on the welfare of my *alma mater*, the University of Edinburgh, and the other universities of Scotland. This last culminating instance is decisive. I cannot hesitate to withdraw from a movement which, it would seem, is to be promoted in utter disregard of the interests of our great Medical school; and I gladly thus free myself from even the remotest semblance of implication in the more recent proceedings of its advocates.—I am, &c.,

WILLIAM SWAN.

Dr. M. Charteris has been elected physician to the Royal Infirmary, Glasgow, in room of Professor Simpson, resigned.

Foreign Medical Literature.

CONTRIBUTIONS TO THE PATHOLOGY OF THE BLOOD.

By PROF. S. STRICKER, of Vienna.

(Translated for the MEDICAL PRESS, by E. B. BRONSON, M.D., from the *Archiv. für Dermatologie und Syphilis*, II. Heft, 1872.)

(Continued from page 109.)

THE phenomena of growth now gained a more precise significance. I have already declared that in accordance with observations of the blending together of two cor-

puscles, the growth observed may be explained through apposition. I have thereby merely declared in what light the thing had presented itself to me before I could avail myself of further observations.

I made allowance for the conditions, in order not to commit myself to a supposition which was still open to objections. For often as I had seen two corpuscles unite themselves, I never saw, however, such an union as of two drops. When two drops lie near each other they may cleave to each other a long time and present the bud form; but so soon as any point of their surface has been sacrificed, so soon as their bulk has become at any point confluent, then they form themselves quickly to a single drop. But with our corpuscles it proceeded more slowly, the contours altered themselves gradually; from the bud form came the biscuit form, then one segment after another was taken up, then there was yet visible upon the upper or uppermost surface the mark of division, till finally, the oblong form without a trace of division was completed. The corpuscle rested again in the oblong form for some little time. I then saw how for the first time facets were formed, which again disappeared. The final result of all these movements was at length the sphere. With the sphere the state of rest was given. I desired not to define these rather unfruitful form-changes as phenomena of life, as I was unable to observe the disappearance and return of certain fixed forms. I was aware, however, that these form-changes frequently occur in protracted dividing processes. Also it was just as plausible to assume that two approximate corpuscles that suddenly advance towards each other, were united by means of a contractile fibre as that they approached each other through mutual attraction.

I have too often observed in the dividing processes in the tissues of the frog, either cut out or exposed to view, how two halves of a cell proceed away from each other until they remain joined by a thin fibre; how, sometimes, the fibre altered its optical properties till it became invisible; how it then had the appearance as though the division were completed, and then afterwards the divided products advanced towards each other and by degrees blended together. Moreover, it is familiar to all tissue-pathologists that pus-corpuscles, so long as they exist under certain conditions for division vegetate so that they attain an inconsiderable size. But as soon as the conditions for division are unfavourable they grow considerably and begin then to form permanent tissue. With all these experiences harmonised the observations made upon our corpuscles; the observations that with a temperature of 22—25° C. their growth was considerable, but with a temperature of 38° C. they increased less in size but, on the other hand, more in numbers.

We have gained, as we see, beside the phenomena perceived on warning the preparation, a considerable series of characteristics for the assumption that the corpuscles are organisms—characteristics insufficient in themselves to maintain the assumption, but which, however, find their exact place in the picture taken as a whole.

We have to do with organisms which by a temperature below 10° C. are only slowly developed, and perhaps not at all by a temperature considerable lower; with a temperature of 20—25° C. their development proceeds pretty rapidly, and still more rapidly at the temperature of the human body. If they have once attained a certain size they then persist as spheres or discs (it was impossible in many cases for me to make the differential diagnosis), either in the state of rest or as dead bodies; it is then possible to keep them for days, even when the blood preparation is destroyed by the vapour of water.

These organisms multiply by budding or division. An outgrowth to larger fibres or stems has, however, at no point and under none of the conditions fixed by me, come to my notice.

Their development is essentially favoured by the vicinity of a larger number of blood corpuscles, and again by the vicinity of air bubbles. In general, they

will be sooner found where a clear plasma-space is bounded on the one side by air, and on the other by a thickish layer of blood-corpuscles. If the specimens be prepared after the pattern given above, and then the whole border be searched, it will be almost impossible, if they appear at all, to overlook them.

Where they have grown under my eye they have certainly spread from the air boundary towards the centre of the preparation. But that is not to be understood as though I had seen the granules advancing. I have, on the contrary, observed that the finest granules always became visible in a zone simultaneously. But it was from a zone in the vicinity of an air bubble that they first emerged; thereupon the whole neighbouring plasma-space was soon filled with them, and only later was I able to make an analogous observation in those spaces next distant.

With regard to the source from which these organisms take their origin, there exist the following alternatives. They either originate from the air or from the blood, and in the latter case the germs were either present in the circulating blood or have subsequently sprung up by spontaneous generation.

The last part of the alternative will find, indeed, but few adherents, and I have myself no wish to be counted amongst these. But no one, also, will deny that the *generatio æquivoca* must in the present case come into consideration as one of the possibilities. For so soon as we have come to assert that organisms have sprung up from germs which are not to be seen with the best microscopes now existing, we assert something which may not be proved as long as the possibility of a *generatio æquivoca* is not with all imaginable sureness excluded.

In the case that the germs originate directly or indirectly from the air we have, perhaps, to do with organisms which are quite familiar under other forms, perhaps with bacteria, which finally occur in every incubating preparation. Only, then, were we obliged to suppose that in the blood of certain persons they take on a mode of development and form which, according to my knowledge, have not yet been made known.

The circumstance that the development begins first where the plasma borders on a film of air, perhaps speaks in favour of their derivations from the air. But it is also to be considered, that perhaps the adjacent air merely favours the conditions to the development. This it so much the more to be taken into consideration, inasmuch as I have also learned that the development progresses best when the film of blood, by which the plasma space (*plasma-kiesel*), is bounded on the other side, attains a certain thickness.

Let us suppose finally that these newly made known organisms take their origin neither directly nor indirectly from the air, and at the same time do not arise in the way of the *generatio æquivoca*. In this instance, we must think it possible, that in the blood of an individual there circulate offspring (*abkömmlinge*) of the cells of this individual or of other similarly constituted individuals, which the former (the blood) has taken up from the genital secretions, or has received by transmission from one individual to another. The supposition that such offspring of cells should, from their minuteness, be invisible with the best microscopes now existing, is thoroughly hypothetical. But we must again admit that their existence is for the present not excluded.

I now turn to the second question. Do the organisms under consideration occur only in the blood of syphilitic persons? To this question I must, to begin with, reply—No.

I have, in all, examined thirteen cases of general syphilis, and in these I met with them nine times in great numbers, in two cases they were certainly not to be found, and in two cases they were so isolated, that I had to regard them as negative. For the cases examined by me, **there, we have to set nine against four.**

I had, in the beginning of my investigation, in ten cases

of healthy, well nourished individuals, in one case of pneumonia, in one with vitium cordis, in four cases of typhus abdominalis, in one case of typhus exanthematicus, and in ten cases of small-pox, not found a trace of these corpuscles.

Medical News.

The Director-General presents his compliments to the Editor of the MEDICAL PRESS AND CIRCULAR, and begs to enclose for insertion a list of candidates for the Army Medical Service who competed successfully at the examinations held in London in February, and at Netley, in August, 1872, after having passed through a course at the Army Medical School, Netley.

University of London.—The following Candidates have passed the first M.B. Examination:—

First Division.

Crocker, Henry Radcliffe, University College.
Duncan, Peter Thomas, University College.
Gould, Alfred Pearce, University College.
Herman, George Ernest, London Hospital.
Houghton, Walter Benoni, University College.

Second Division.

Barrow, Albert Boyce, King's College.
Batterbury, George Henry, King's College.
Briggs, George Chapman, King's College.
Garlick, George, University College.
Harris, Vincent Dormer, St. Bartholomew's Hospital.
Hetley, Henry, Guy's Hospital.

SYCOSIS.

DR. WHITE believes that great confusion exists amongst dermatologists regarding the pathology of sycosis, and which can be accounted for by the circumstance that there are two distinct affections of the beard, closely resembling each other in appearance, but due to different causes. Sycosis he defines as a chronic inflammation of the hair follicles of the face. It begins slowly in the form of a nodule at the root or insertion of a hair, and when the inflammation runs high, pus is formed, which dries, and forms a crust about the hair. This process is repeated in the individual follicles several times. The tissues beneath the skin in time become involved, and large abscesses are formed, and thus the disease may go on for months, or even years. It is a disputed point whether sycosis is due to a fungus or not. Many authorities, as Hebra, believe if a fungus is present it is only an accidental complication; whilst others, as Gruby and Anderson, hold the belief of its cryptogamic origin, the fungus being identical with that found in ringworm of the head, due to the presence of the trichophyton tonsurans. Dr. White agrees with the last mentioned view, and brings forward in support thereof the recent opinion of Prof. Tanturri, published in the *Italian Dermatological Journal*, who holds that tinea tonsurans occurs first, and that sycosis is the direct consequence of it, being contagious, and is distinguished from the idiopathic sycosis (acne of beard) by its morphological, clinical, and anatomical characters. The ancient Romans were very liable to sycosis, said to be due to the habit of the men kissing each other.

With regard to the supposed identity of the vegetable parasites, and their relations to common mould, Dr. White enters very fully into the conflicting opinions held, not only by dermatologists, but by botanists; however, Köbner, Petyritsch, Karsten, and De Barry have never found any difficulty in obtaining penicillium and the like in their cultivation of favus matter; they regard its presence in their experiments as merely accidental. The elements of penicillium, aspergillus, &c., are omnipresent, awaiting only the proper conditions of soil, temperature, and moisture for development, so that unless their germs are primarily excluded by the most rigorous measures from the materials and atmosphere used in these experiments, their constant appearance under circumstances best adapted to their growth is not surprising, though their absence would be. Such exclusion has been found nearly impossible. De Barry believes that the fungus of favus is a specific parasite, and Neuman rejects his former opinion, viz., that the fungus of favus can be traced to penicillium. Dr. White thinks that, with regard to the identity of the fungi found in cutaneous affections, we must still maintain their specific individuality, because clinically they are distinct, notwithstanding the deceptive inferences drawn from accidental coincidences, and because neither the results of transplanting nor of artificial cultivation have been such as to counterbalance even the negative evidence drawn from the same source; and with regard to their identity with any of the common moulds, the evidence presented is still more questionable.—*The Doctor*.

VEGETABLE PARASITES, AND DISEASES CAUSED BY THEM UPON MAN.

The Third Annual Report of the State Board of Health of Massachusetts, 1872, contains a very interesting paper

upon Vegetable Parasites, and the Diseases caused by their Growth upon Man. The author of the paper is Dr. James C. White. He divides his subject under the following heads:—1. The nature of vegetable parasites. 2. The diseases to which they give rise upon man. 3. Pseudo-parasites. 4. Their growth upon domestic animals. 5. Their supposed identity and relation to common mould (penicillium glaucum). And 6. Common sources of contagion, and precautions to be used against them. Dr. White describes eczema marginatum as one of the varieties of "ringworm," and it is to Hebra we are indebted for the true explanation of this very interesting affection. Eczema marginatum begins as a small round patch of papules and vesicles, with itching, and that excites scratching, usually situated about the inner surface of the thighs and lower part of abdomen. As the disease spreads, it heals in the centre, leaving a dark red, scaly condition of the skin, whilst the advancing border presents an elevated ridge of papules, vesicles, and other lesions of eczema upon an inflamed base. This affection differs from eczema in its nature, and in the central retrogression and concentration of its activity in the advancing edge. Eczema marginatum, Dr. White believes, differs only from ordinary ringworm (tinea circinata) in the more eczematous character of the lesions which compose the outer ring, and the greater amount of active congestion and pigmentation that remains behind. The parasite in common ringworm creates a certain amount of irritation of the skin, expressed by the formation mainly of papules and vesicles; but in eczema marginatum the inflammatory process is aggravated, as shown by the addition to the lesions just mentioned of pustules and crusts, and greater exudation beneath where the source of the irritation is most actively at work, namely, at the edge.—*The Doctor*.

Gleanings.

Veratrum Viride as an Arterial Sedative.

DR. JOHN S. WILSON states: (*Atlanta Med. Jour.*) "Veratrum is one of the few drugs in the administration of which we can have the unerring guide of figures as to the regulation of the dose. And so uniform and certain in its sedative action that we can confidently predicate our directions on this result. Therefore, all we have to do in the administration of the remedy is to begin with a minimum dose and gradually increase until the desired reduction of the pulse is accomplished, as counted by the watch. My practice has been to begin with two or three drops of tincture for an adult, repeated every three hours, increasing one drop each dose until the pulse is reduced to the normal standard. When this is attained, I diminish the dose to one drop, and discontinue if the pulse sinks below the point mentioned. By pursuing this course I have succeeded in effecting the desired sedation in almost all cases without nausea, vomiting, or other disagreeable symptoms. Close observation has taught me that three hours, as a general rule, is the proper interval between doses, the previous dose requiring support in about this time."

Chloral in Cough, Asthma, Etc.

DR. N. H. CANADAY, of Knightstown, Ind. (*Ind. Jour. Med.*), in an interesting paper on the therapeutical applications of chloral, reports, among others, the following case:—"A child, 11 months old, had colitis in the early part of the summer, with frequent relapses since—was enfeebled and emaciated—took measles, attended with an incessant cough, which harassed it day and night, preventing sleep. It took one and a half grains of chloral every two hours, in simple syrup for a week, which kept the cough quieted. If it was left off for a few hours over the time the cough would become very harassing, but on giving the chloral again it was soon relieved. After continuing it for a week or more it was afterwards given occasionally, as the cough seemed to require. I have used it in several cases of bronchorrhœa with the same effect, apparently of relieving cough and drying up the secretion; have given it to small children in grain doses frequently repeated, for colic, restlessness, &c., and find it the best soothing syrup that I have ever used."

ETHER *versus* CHLOROFORM.

ON THE USE OF ETHER AS AN ANÆSTHETIC IN SURGICAL OPERATIONS; AS A SAFER AND MORE EFFECTIVE AGENT THAN CHLOROFORM IN PRODUCING THE AVOIDANCE OF PAIN.

With a Description of an Inhaler, and the Mode of Administration.

By J. MORGAN, M.D., F.R.C.S.,

Professor of Surgical and Descriptive Anatomy Royal College of Surgeons, Dublin, Surgeon to Mercer's Hospital, &c.

(Continued from page 105.)

THE PULSE WRITING IN ETHERIZATION.

The critical examination into the comparative merits of Ether and Chloroform which I have already referred to, as conducted by the Committee of Investigation ap-

pointed by the Royal Medical Chirurgical Society of London, resulted in important observations.

The inquiry was aided by the use of the hemadynamometer in testing the effect of the heart's action and of the influence of these agents upon it. The report states—"The essential difference between the action of Chloroform and of Ether is to be found in the effect produced upon the heart. The first operation of both agents is to stimulate the heart and augment the force of its contractions; but, after this, Chloroform *depresses* the heart's action, whereas Ether appears to exert but little influence upon the muscular movements of that organ." The general accuracy of this remark, though tested by so comparatively coarse an instrument, is borne out by observation of the pulse writing as indicated by the Sphygmograph, an instrument of far greater delicacy which has been since introduced into practice; it affords direct instruction in comparing the influence of Etherization on the pulse, with the healthy condition, by the evidence of the writing.

The accompanying outline of the principle of the Sphygmograph will serve to explain briefly its mode of action, as writing from the natural soft pulse:—

FIG. 1.

- a. The pulse, showing the artery in the act of pulsation.
 c. k. The lever, which communicates its pulsations by being laid on the wrist.
 f. l. The index, or pen, which marks the pulsations on a slip of paper, or glass, which receives the writing by being worked along by a rack and spring.

On examining a pulse writing, the component motions may be thus analysed—

1. The First Ascent. Due to the jerk, by the propelling heart.
 2. The Indentation. Due to the elastic re-action of the blood-vessel itself.
 3. The Elevation. Due to the continued force of the heart's contraction, sending on the blood fluid.
 4. The Break. Due to the sudden stopping off, of the heart's action by the valves shutting.
 5. The Second Elevation. Due to the action of the blood-vessel itself.

It has already been shown by the Chloroform Committee above quoted, that Ether exercises a stimulating effect on the heart's action, instead of the depressing and sometimes fatal one of Chloroform. It therefore follows that sphygmographic delineations, or pulse writings, should give some aid, as typifying the immediate effect of Etherization on the heart itself. If the general influence of the "vis a tergo" due to the immediate propulsion of the blood from the heart be understood, in causing the ascent of the pulse writing, with its succeeding fulness or distension, such evidence will be interesting, as showing the condition and vigor of the heart's action during the sleep of Etherization.

In order to simplify the general conclusions as to the value of the indications, I add a bird's-eye view of some of the modifications of pulse writings in various diseased conditions—more particularly with regard to the indications due to the "vis a tergo," or immediate influence of the heart.

Typical pulse writings of opposite characters will be instructive. Thus—taking an example of enlargement of the heart (Fig. 2). The high elevation of the pulse writing is remarkable, compared with undulatory score of typhus fever (Fig. 3.) or again with the feeble indications of the flickering heart of a patient worn out by consumption, given during the last hour of life (Fig. 4).

FIG. 2.

Pulse Writing given by an Enlarged Heart.

FIG. 3.

Pulse Writing in Typhus Fever.

FIG. 4.

The feeble Pulse Writing of an Expiring Heart.

If these be compared with the copy of a writing given by the "Natural soft pulse after exercise and residence in the country," as shown in Fig. 1, the relative conditions and indications may be estimated.

The following specimens of pulse writing, taken both previous to, and during Etherization, prove that the effect on the heart was that already mentioned by the Chloroform Committee in 1864—

"That Ether was a stimulant to its action."

Fig. 5. represents the pulse of a female patient, aged 25, who had been confined in bed for five months; pulse writing taken before Etherization.

Fig. 6. represents it during the full influence. It will be seen that the heart power indication was rather stronger during Etherization than before.

FIG. 5.

FIG. 6.

I selected another instance of a female, aged 17, also long confined in bed. The contrast of Fig. No. 7. taken before Etherization, and of Fig. No. 8. during profound Etherization is not able. The elevation of the pulse line, showing the stimulating property of the Ethereal influence.

FIG. 7.

FIG. 8.

Fig. 9. represents the excited pulse writing of a small and nervous female patient, previous to Etherization and operation.

FIG. 9.

Fig. 10. represents the pulse writing of the same patient, when steadied by Etherization. The contrast is remarkably favourable.

FIG. 10.

Fig. 11 represents the pulse writing of a healthy young man of 22, previous to operation for artificial pupil—an affection which had not interfered with his general health.

FIG. 11.

Fig. 12. represents the same, when taken under full Etherization and after the completion of the operation. A comparison of this pulse writing with that of Fig. 1. will be ample evidence of the safety of Etherization in its action on the heart.

FIG. 12.

I have taken all but one of these examples as the most unpropitious, occurring in patients of diminished health and vitality, yet it is evident that the most perfect anaesthesia could be invoked under the influence of Ether, with an absolute stimulating effect on the circulation, and that the condition of insensibility could be maintained for a considerable time, yet there was no material alteration of the "pulse writing," and the most perfect sense of security was established.

It is therefore established that—

WHILE CHLOROFORM EXERTS A DEPRESSING INFLUENCE ON THE HEART,
ETHER EXERTS A STIMULATING ONE;
AND THAT CHLOROFORM IS THE MOST DANGEROUS,
WHILE ETHER IS IMMEASURABLY THE SAFEST OF ALL ANÆSTHETICS.

On the opposite side it has been stated that

The only Argument in favour of the use of Chloroform is that of its being convenient (a).

However, on the other hand the only objections which have been put forward by the Committee as bearing against the use of Ether were the comparatively insignificant ones of "disagreeable odour," that it was "slower," and gave rise "to greater excitement than Chloroform." The odour of Chloroform, it is to be admitted, is sweeter and perhaps the most agreeable. Few people, however, dislike the odour of Ether, and whatever objection there may be to the flavour, its exhilarating effects are such that many have found it a seductive substitute for alcoholic stimulants, even to the extent of producing intoxication. In Ireland, curiously, its virtues, if they may be so styled in this way, have been already appreciated, and as that province, whose inhabitants are peculiarly accredited with astuteness, has been the most noted for its consumption, we may conclude that it presents, despite its supposed disagreeable odour, the recommendation of being "good value" in producing the desired effects; indeed, the intoxicating and stimulating quality of Ether has been known for a considerable time, and a *souppçon* of its use amongst the better classes of society has more or less existed. Mr. Draper (b), however, has lately put the question of the "*Use of Ether as an Intoxicant*" in so clear a light that it has attracted considerable attention. He states:—

"The floating idea that there are fair consumers of *Hoffmann's anodyne* and *perles d'ether*, for whom ether has never been prescribed, quite prepares one for the discovery that there is in the northern part of Ireland a number of people who, forswearing alcohol, supply its place with ether—a race to whom ether is what koumiss is to a Kalmuck, ava to a South Sea Islander, absinthe to a certain class of Frenchmen, or gin and whiskey to their more immediate neighbours. That they should take 'nips' of ether morning, noon, and night, as they would whiskey, and—for anything shown to the contrary—drink good luck or ratify bargains in a glass of ether, was not a thing to look for, and is, perhaps, without parallel in the history of narcotic stimulants. The facts rest upon the authority of a number of gentlemen, in their respective capacities of physicians, clergymen, ether manufacturers, and druggists."

Its Mode of Use.

"The usual quantity of ether taken at one time is from two to four drachms, and this dose is repeated twice, thrice, or even four and six times daily. It is taken unmixed with water; indeed, its very slight solubility in that fluid would make this a useless precaution; but the usual practice is, to take first a mouthful of water, then the dose of ether, and again a mouthful of water."

Its Effect.

"The intoxication produced by ether resembles that of alcohol, but is much more rapidly produced, and is more evanescent. The ether seems to be eliminated entirely by the lungs, and the breath of the ether drinker always affords ample evidence of his addiction to the habit. I am credibly informed that at the fair of Draperstown—which appears to be the paradise of ether drinkers—the prevalent smell is not, as at country fairs, of pigs, tobacco-smoke, or of unwashed human beings, but of ether."

Its Influence on the Health.

"I have not been able to learn that, apart from the moral ill effects common to all excitants and intoxicants, the habitual use of ether brings in its train any peculiar evils, and although it would be wrong to draw a conclusion from completely negative evidence, I am disposed to believe that the votaries of ether incur less danger from the habit than ordinary dram-drinkers; and there are two good reasons for this belief. If we assume that there is nothing specifically injurious in the action of ether, it will

(a) Erichsen.

(b) Mr. Draper in the *MEDICAL PRESS AND CIRCULAR*.

readily be admitted that, having a definite chemical composition, and not being very liable to adulteration with other fluids, it must be an improvement upon the sophisticated alcoholic potations, which, with these people, it has replaced. Again, the affinity of ether for water is so slight (a) that dehydration of the mucous tissue of the alimentary canal, and that apeptic action which so well mark the difference between the effect of ardent spirits and of alcohol in the form of unbranded wine, cannot be evils attending its use.

"All the ether consumed in this way is that which is technically termed 'methylated,' that is, prepared from methylated spirit."

The Quantity Consumed.

"Now, if we assume the ordinary quantity taken at one time to average three drachms, and this quantity to be (in stimulant effect) the equivalent of half a glass of whiskey, we arrive at the result that three gallons of ether supply the place of ten gallons of whiskey. It is very difficult to arrive at any accurate idea of the extent to which ether is consumed in the north of Ireland. Omagh is said to take about 400 Winchester quarts (equal to 250 gallons) yearly, and one Dublin manufacturer has sent to Belfast at the rate of 4,000 gallons yearly."

The consumption of ether in repeated doses appears, therefore, to have had no specially prejudicial effect on the health; while it acts as an intoxicant more rapidly than spirits, it is more evanescent. We may conclude from the experience of the ether drinkers of the north of Ireland that the vapour may be freely used, and the anæsthetic influence unhesitatingly invoked without having any permanent or deleterious effect, although the system may have been as it were saturated, as it doubtless is, by the ether tippler who imbibes his two or three teaspoonfuls perhaps six times in one day—an amount more than sufficient to exercise full insensibility by the mere inhalation of its vapour.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE great scientific congress of the year has this time been held at Brighton, and was very successful. The feature of the meeting was the presence of Mr. Stanley, the discoverer of Dr. Livingstone, who was welcomed with the greatest enthusiasm, and whose speech was simple, clear, and effective. The President this year was Dr. W. B. Carpenter, and our Profession may feel gratified at the manner in which this eminent member filled the office.

PRESIDENT'S ADDRESS.

DR. CARPENTER'S address set out with a retrospect of his thirty-six years' connection with the Association, dating from its first and only meeting at Bristol. The "fathers and elder brothers" of that day—Whewell and Peacock, James Forbes and Sir William Rowan Hamilton, Buckland and De la Beche—where were they? One of these great men whose departure had occurred since they last met claimed special notice. How they should have sympathised with Murchison in the delight with which he would have heard of the safety of the friend in whose scientific labour and personal welfare he felt to the last the keenest interest. That this intelligence should have been brought to them through the generosity of one and the enterprising ability—might he not use the peculiarly English word "pluck"?—of another of our American brethren, could not but be a matter of national regret. Let them bury that regret in the common joy which both nations feel in the result; and, while giving a cordial welcome to Mr. Stanley, let them glory in the prospect now opening that England and America will co-operate in the glorious object which, far more than the discovery of the sources of the Nile,

(a) 1,000 volumes of ether dissolves but 10 volume of water.

the great traveller has set before himself as his true mission, the destruction of the slave trade. In reviewing the scientific progress of the past year, Dr. Carpenter announced that liberal arrangements had been made by the Government for prosecuting on a more extended scale the inquiry into the physical and biological conditions of the deep sea, on which he, with Professor Wyville Thompson and Mr. Gwyn Jeffreys, had been engaged for three years. H. M. S. Challenger was being fitted out at Sheerness for a circumnavigating expedition to be organised by a commission on which the Association was represented. Professor Wyville Thompson would take the scientific charge of it, and it was expected to sail in November next. A brief allusion was made to the Eclipse Expedition sent out to India under Mr. Norman Lockyer, from which it was said that a most valuable body of results had been obtained, and were about to be published, under the direction of the council of the Astronomical Society. Previous inaugural discourses had generally taken up some aspect of nature in her relation to man. The President was not aware that any one of them had turned to the other side of the inquiry—that which concerned man as the interpreter of nature. He thought it, therefore, not inappropriate to consider the mental processes by which are formed those fundamental conceptions of matter and force, of cause and effect, of law and order, which furnish the bases of all scientific reasoning and constitute the *philosophia prima* of Bacon. They were primarily concerned with the intellectual representation of nature, the two other principal characters in which man acted as her interpreter being those of the artist and the poet. All artists looked at nature with different mental eyes, and to each nature was what they individually saw in her. It was the object of the poet to represent what he felt in nature, and to him nature was what he individually found in her. "There is a class of cases in which certainty is generally claimed for conclusions that seemed to flow immediately from observed facts, though really evolved by intellectual processes; the apparent simplicity and directness of those processes either causing them to be entirely overlooked, or veiling the assumptions on which they are based. Thus Mr. Lockyer speaks as confidently of the sun's chromosphere of incandescent hydrogen, and of the local outbursts which cause it to send forth projections tens of thousands of miles high, as if he had been able to capture a flask of this gas, and had generated water by causing it to unite with oxygen. Yet this confidence is entirely based on the assumption that a certain line which is seen in the spectrum of a hydrogen flame, means hydrogen also when seen in the spectrum of the sun's chromosphere; and, high as is the probability of that assumption, it cannot be regarded as a demonstrated certainty, since it is by no means inconceivable that the same line might be produced by some other substance at present unknown. And so when Dr. Huggins deduces from the different relative positions of certain lines in the spectra of different stars, that these stars are moving from or towards us in space, his admirable train of reasoning is based on the assumption that these lines have the same meaning—that is, that they represent the same elements—in every luminary. But when Frankland and Lockyer, seeing in the spectrum of the yellow solar prominences a certain bright line not identifiable with that of any known terrestrial flame, attribute this to a hypothetical new substance which they propose to call helium, it is obvious that their assumption rests on a far less secure foundation, until it shall have received that verification which, in the case of Mr. Crooke's researches on thalium, was afforded by the actual discovery of the new metal, whose presence had been indicated to him by a line in the spectrum not attributable to any substance then known. And I think it can be shown that the trustworthiness of this common-sense decision arises from its dependence, not on any one set of experiences, but upon our unconscious co-ordination of the whole aggregate of our experiences—not on the conclusiveness of any one train of reasoning, but on the convergence of all our lines of thought towards this one centre."

The President then went on to explain the distinctive features of the two schools of thought which attribute our primary beliefs respectively to intuition and experience, and to point out how they might be harmonised by the theory of inheritance, an opinion in which he said Mr. Mill, to a great extent, concurred. Having dealt at some detail with our notions of matter and space as sense-perceptions, the President passed to the consideration of the general conceptions to which experience gives rise—the laws of nature.

Dr. Carpenter summed up his argument in the following terms:—

Now since it is universally admitted that our notion of the external world would be not only incomplete, but erroneous, if our visual perceptions were not supplemented by our tactile, so, as it seems to me, our interpretation of the phenomena of the universe must be very inadequate, if we do not mentally co-ordinate the idea of force with that of motion, and recognise it as the "efficient cause" of those phenomena—the "material conditions" constituting (to use the old scholastic term) only "their formal cause." And I lay the greater stress on this point, because the mechanical philosophy of the present day tends more and more to express itself in terms of motion rather than in terms of force; to become kinematics instead of dynamics. Thus from whatever side we look at this question—whether the common sense of mankind, the logical analysis of the relation between cause and effect, or the study of the working of our own intellects in the interpretation of nature—we seem led to the same conclusions that the notion of force is one of those elementary forms of thought with which we can no more dispense than we can with the notion of space or of succession. And I shall now, in the last place, endeavour to show you that it is the substitution of the dynamical for the mere phenomenal idea, which gives their highest value to our conceptions of that order of nature which is worshipped itself as a God by the class of interpreters whose doctrine I call in question. The most illustrative as well as the most illustrious example of the difference between the mere generalisation of phenomena and the dynamical conception that applies to them, is furnished by the contrast between the so-called laws of planetary motion discovered by the persevering ingenuity of Kepler, and the interpretation of that motion given us by the profound insight of Newton. Kepler's three laws were nothing more than comprehensive statements of certain groups of phenomena determined by observation. The first—that of the revolution of the planets in elliptical orbits—was based on the study of the observed places of Mars alone; it might or might not be true of the other planets; for so far as Kepler knew, there was no reason why the orbits of some of them might not be the eccentric circles which he had first supposed that of Mars to be. So Kepler's second law of the passage of the radius vector over equal areas in equal times, so long as it was simply a generalization of facts in the case of that one planet, carried with it no reason for its applicability to other cases, except that which it might derive from his erroneous conception of a whirling force. And his third law was in like manner simply an expression of a certain harmonic relation which he had discovered between the times and the distances of the planets, having no more rational value than any other of his numerous hypotheses. Now the Newtonian "laws" are often spoken of as if they were merely higher generalizations in which Kepler's are included; to me they seem to possess an altogether different character. For starting with the conception of two forces, one of them tending to produce continuous uniform motion in a straight line, the other tending to produce a uniformly accelerated motion towards a fixed point, Newton's wonderful mastery of geometrical reasoning enabled him to show that, if these dynamical assumptions be granted, Kepler's phenomenal "laws" being necessary consequences of them, must be universally true. And while that demonstration would have been alone sufficient to give him an imperishable renown, it was his still greater glory to divine that the fall of the moon towards the earth—that is, the deflection of her path from a tangential line to an ellipse—is a phenomenon of the same order as the fall of a stone to the ground; and thus to show the applicability to the entire universe, of those simple dynamical conceptions which constitute the basis of the geometry of the principia. Thus, then, whilst no "law" which is simply a generalization of phenomena can be considered as having any coercive action, we may assign that value to laws which express the universal conditions of the action of a force the existence of which we learn from the testimony of our own consciousness. The assurance we feel that the attraction of gravitation must act under all circumstances according to its one simple law is of a very different order from that which we have in regard (for example) to the laws of chemical attraction, which are as yet only generalizations of phenomena. And yet even in that strong assurance we are required by our examination of the basis on which it rests to admit a reserve of the possibility of something different—a reserve which we may well believe that Newton himself must have entertained. A most valuable lesson as to the allowance we ought always to make for the unknown "possibilities of Nature" is taught us by an exceptional phenomenon

so familiar that it does not attract the notice it has a right to claim. Next to the law of the universal attraction of masses of matter there is none that has a wider range than that of the expansion of bodies by heat. Excluding water and one or two other substances, the fact of such expansion might be said to be invariable; and, as regards bodies whose gaseous condition is known, the law of expansion can be stated in a form no less simple and definite than the law of gravitation. Supposing those exceptions, then, to be unknown, the law would be universal in its range. But it comes to be discovered that water, whilst conforming in its expansion from 39½ deg. upwards to its boiling point, as also, when it passes into steam, to the special law of expansion of vapours, is exceptional in its expansion also from 39½ deg. downwards to its freezing point; and of this failure in the universality of the law no *rational* can be given. Still more strange is it that by dissolving a little salt in water we should remove this exceptional peculiarity; for sea-water continues to contract from 39½ deg. downwards to its freezing point 12 deg. or 14 deg. lower, just as it does with reduction of temperature at higher ranges. Thus from our study of the mode in which we arrive at those conceptions of the orderly sequence observable in the phenomena of Nature which we call "laws," we are led to the conclusion that they are human conceptions, subject to human fallibility; and that they may or may not express the ideas of the great Author of Nature. To set up these laws as self-acting, and as either excluding or rendering unnecessary the power which alone can give them effect, appears to me as arrogant as it is unphilosophical. To speak of any law as "regulating" or "governing" phenomena is only permissible on the assumption that the law is the expression of the *modus operandi* of a governing power. I was once in a great city which for two days was in the hands of a lawless mob. Magisterial authority was suspended by timidity and doubt; the force at its command was paralysed by want of resolute direction. The "laws" were on the statute book, but there was no power to enforce them. And so the powers of evil did their terrible work; and fire and rapine continued to destroy life and property without check, until new power came in, when the reign of law was restored. And thus we are led to the culminating point of man's intellectual interpretation of Nature—his recognition of the unity of the power of which her phenomena are the diversified manifestations. Towards this point all scientific inquiry now tends. The convertibility of the physical forces, the correlation of these with the vital, and the intimacy of that nexus between mental and bodily activity, which, explain it as we may, cannot be denied, all lead upward towards one and the same conclusion, and the pyramid of which that philosophical conclusion is the apex has its foundation in the primitive instincts of humanity. By our own remote progenitors, as by the untutored savage of the present day, every change in which human agency was not apparent was referred to a particular animating intelligence. And thus they attributed not only the movements of the heavenly bodies, but all the phenomena of Nature, each to its own deity. These deities were invested with more than human power; but they were also supposed capable of human passions, and subject to human capriciousness. As the uniformities of Nature came to be more distinctly recognised, some of these deities were invested with a dominant control, while others were supposed to be their subordinate ministers. A serene majesty was attributed to the greater gods who sit above the clouds; whilst their inferiors might "come down to earth in the likeness of men." With the growth of the scientific study of Nature the conception of its harmony and unity gained ever-increasing strength. And so among the most enlightened of the Greek and Roman philosophers we find a distinct recognition of the idea of the unity of the directing mind from which the order of Nature proceeds; for they obviously believed that, as our modern poet has expressed it:

"All are but parts of one stupendous whole,
Whose body Nature is, and God the soul."

The science of modern times, however, has taken a more special direction. Fixing its attention exclusively on the order of Nature, it has separated itself wholly from theology, whose function is to seek after its cause. In this Science is fully justified, alike by the entire independence of its objects and by the historical fact that it has been continually hampered and impeded in its search for the truth as it is in Nature by the restraints which theologians have attempted to impose upon its inquiries. But when Science, passing beyond its own limits, assumes to take the place of theology, and sets up its own

conception of the order of Nature as a sufficient account of its cause, it is invading a province of thought to which it has no claim, and, not unreasonably, provokes the hostility of those who ought to be its best friends. For whilst the deep-seated instincts of humanity and the profoundest researches of philosophy alike point to mind as the one and only source of power, it is the high prerogative of Science to demonstrate the unity of the power which is operating through the limitless extent and variety of the universe, and to trace its continuity through the vast series of ages that have been occupied in its evolution.

BRITISH MEDICAL ASSOCIATION.

ADDRESS IN SURGERY.

BY

OLIVER PEMBERTON, Esq.,

Surgeon to the General Hospital, and Professor of Surgery in Queen's College, Birmingham; Foreign Corresponding Member of the Society of Surgery of Paris; etc.

To solicit your attention to some moot points connected with the treatment of aneurism, is sufficiently appropriate in itself, if we only consider the increasing interest that at present surrounds it, and the impetus that must be given to its study by the exhaustive nature of the lectures now in course of delivery before the College, by Professor Holmes; but I cannot forget that we are assembled in Birmingham, where Freer and Hodgson lived and wrote—illustrious pair!—well fitted to be teacher and pupil. I cannot forget that George Freer was the first to tie successfully the external iliac artery (4th October, 1806), and that Joseph Hodgson (*Treatise on the "Diseases of Arteries and Veins."* London: 1815) paved the way to a clearer perception of the pathology of arteries and veins than had existed since the days of Hunter. So it is an appropriate tribute to their labours, that here, in this place, I should have the subject of aneurism foremost in my mind.

Professor Lister's improvement in the Hunterian operation, by which the permanent closure of the artery at the spot tied can be insured, without dividing the coats of the vessel, at once effects a complete change in some of the most important conclusions that for long years have guided us in our treatment of aneurism. One of the greatest dangers attending the Hunterian operation has hitherto been considered to be the application of the ligature immediately beyond any considerable branch of an artery. This impression has deterred surgeons from applying a ligature to that portion of the artery which otherwise would have seemed to them best adapted for the purpose. That an abiding coagulum will form under certain circumstances in the vicinity of almost any number of branches on the proximal side of a ligature, I am perfectly satisfied; but the attainment of this success in many cases depends on a fact which it is almost impossible for the surgeon to estimate beforehand; that is, the facility with which the blood will coagulate or deposit its fibrin in any particular instance. In the case I am about to relate, the existence of this tendency, in a much greater degree than usual, was the main cause of the success of the operation.

In June, 1870, I saw F., aged 60, strumous from childhood, and highly intellectual. There was an aneurism, three months old, of the left superficial femoral artery, about five inches below Poupart's ligament. There were marked indications of general arterial disease, and, during the past twelve months, of semi-paralytic seizures, evidently due to temporary hindrance to the cerebral circulation. Pressure failed, and was abandoned at the end of three months. I then advised ligature—the aneurism rapidly increasing. On October 12th, the aneurism having "leaked" the previous day, in the presence and with the sanction of Sir James Paget, I tied the common femoral with a hempen ligature. Fearing, from the diseased state of his arteries, the worst results, as the ligature might be thrown off, the wound was left completely open, being simply covered for protection. In forty days the ligature came away, and the patient died a week afterwards, from causes wholly removed from the aneurism. There was no hæmorrhage, but gangrene may be said to have commenced in one toe. When I came to dissect the arteries I found the

circumflex ilii, epigastric, and the profunda femoris given off together, that is, at opposite points of a line drawn round the main trunk, a little above Poupart's ligament, the point of ligature being five-eighths of an inch below these vessels, the part of artery intervening being firmly plugged. The profunda was pervious for some distance and then plugged. There were plugs of former date in the right and left carotids and in the left axillary arteries. The aneurismal sac was filled by broken down clot and fluid blood, and would have suppurred.

Now, I cannot consider this case as any contribution to the surgery of the common femoral, though I hoped and expected it would be so; for I think hardly any doubt can be entertained that the patient would have died from secondary hæmorrhage on the separation of the ligature, had it not been for the unusual tendency of the blood to coagulate, for nothing could well be closer than those three vessels were to its site. At the same time, I think, with Porter and Macnamara ("On Ligature of Common Femoral," *British Medical Journal*, 2, 1867, p. 285), that the exclusion of the common femoral, on account of the assumed liability to secondary hæmorrhage and gangrene that follows its ligation, is not founded on any solid basis. It was selected in this instance in preference to the external iliac, and I should so select it again, of course on the presumption that I was going to place my ligature in the vicinity only of such branches as the epigastric and circumflex ilii, in the presence of which I feel satisfied that an adequate coagulum may, under ordinarily favourable circumstances, be reasonably expected to form.

It is rather here, then, I draw your particular attention to this feature of coagulation. For I ask myself this question: If I had tied this artery—complicated as its irregularity was in this instance—with a hempen ligature, and there had not existed this tendency, would it have held? Assuredly not. This same tendency to coagulation, as manifested in the collateral vessels, whilst it preserved the patient's life, would, I may observe, have subsequently caused his death by gangrene. Further, it appears to me that in proportion as the coats of the arteries deviate from their natural state, and as the general vital conditions are lowered, so is this tendency increased.

Surgically speaking, then, this very circumstance of diseased arteries and tendency to blood-coagulation, in some cases, establishes a reason why the surgeon should not refrain from operating where the diseased condition of the coats of the arteries alone would lead him to abstain from interference. And it is clearly of the utmost importance to increase this tendency to the coagulation of the blood as much as possible, after all operations for aneurism, by good diet, and by the absence of all depressing remedial agents.

Apart from this question of coagulation, I feel warranted in expressing my conviction that too much stress has been laid on the disturbing influence of a large branch or branches taking origin close to the part of the vessel tied. If, however, we are to believe the teaching of Professor Lister ("Observations on Ligature of Arteries," Edinburgh: 1869), it will be of little moment in future whether a plug form on either the proximal or distal side of the ligature at all, so long as the "prepared catgut" insures permanent closure of the vessel at the spot tied, without severance of the coats, and, consequently, without liability to secondary hæmorrhage.

From what I have seen since this case came under my notice, I am glad, before such a meeting, to be able to express my unbounded admiration of, and confidence in, the use of the animal ligature; as placed before us by Professor Lister. If the so-called "antiseptic system" has effected no more for surgery than to give us the means of effectually closing an artery without cutting it through, and without suppuration, it has in doing this placed the crowning glory on the treatment of aneurism, for which it has waited since the time of Hunter.

For forty days I watched patiently for the detachment of this ligature with an open wound to escape deep-seated suppuration. I watched twenty-one days in a case last May, in which I tied the external iliac for aneurism at Poupart's ligament; and though the case did perfectly well, the suppuration about the track of the hempen cord gave me the greatest anxiety.

Last August, Mr. Lund, at Manchester, tied the same artery with a catgut ligature. No pus was secreted: the wound healed on the eighth day.

Professor Lister remarks that ligature of the innominate must yet prove, with these means at command, "a very safe

procedure." Yes; but always, I presume, provided that the coats of the artery are healthy where the ligature is applied; and on this we await further evidence. Given this, and I feel inclined to echo the assurance.

I shall now endeavour to show that the principles of treatment in the methods of flexion, compression of the sac, and manipulation, are one and the same.

The method of flexion can only be applicable to certain arteries. All that it is needful to do is to keep the limb flexed, not continuously, but to such an extent as to alter the relations between the orifices of ingress and egress, and the fibrinous laminae of the sac. Some of these laminae become, as it were, dislocated, and protrude more or less into the stream when a fresh deposit of fibrin occurs, and so the cure is gradually effected.

The exercise of pressure on the artery above the angle of flexion appears to me useless. What we want is a stream of blood flowing into the aneurism, that it should be more or less retarded there, and that there should be present something in the nature of a foreign body,—for example, the fibrous laminae, on which blood would coagulate and deposit its fibrine. This retardation of the blood in the sac can be effected by a gentle compression of the artery on the distal side of the aneurism, as I strongly hold that what we want in these cases is a deposition of fibrin rather than a coagulation of blood. For, surely, the slow deposition, layer after layer, of solid fibrin in the sac until the filling-in is complete, is a surer guarantee against subsequent mishaps than if it were closed by a mass of suddenly coagulated blood.

I place before you the case of K., a Lascar, aged 22, who came under my care May 10, 1859, having an aneurism of the left popliteal artery of four months' duration. Flexion was maintained for seventy-two hours, with the result of the aneurism ceasing to pulsate, and becoming solid in eleven hours. Compression, during the first forty-eight hours, of moderate character was also made by Weiss's instrument on the artery in Scarpa's space.

I believe that this was the first instance on record in which the combination of compression and flexion was made use of; and the case was published very fully at the time in the *Lancet*. But I feel satisfied now, in reviewing it, that pressure below the sac would have proved more advantageous than above.

If one wanted convincing of the very slight means whereby important curative changes may be brought about in aneurismal sacs, I have but to ask a consideration of the facts connected with the following cure, in thirty-nine hours, of popliteal aneurism.

M., aged 28, a porter, came under my care on the 17th January, 1871, with an aneurism of the right popliteal artery five months old. On the 22nd, I showed the patient how I proposed to treat him—by flexion—at the same time bending his leg, and arresting the circulation through the sac. It is very likely that the patient, in the afternoon, subsequently to my visit, imitated my proceeding, as he seemed very much struck by what I had done. Be this, however, as it may, I only bent the limb once, and fingered the sac lightly, and told him to keep quiet. At two a.m. on the 23rd he was seized with sudden aching, shooting, gnawing pain in the neighbourhood of the aneurism, extending down the calf of the leg as far as the ankle, and upwards as far as the crest of the ilium. The pain continued very intense for some hours, during which he had no sleep. He had severe nausea, but no vomiting, and was chilly. The pulsation in the aneurism seemed unchanged, but he remained poorly all the day.

On the 24th, he slept until three a.m., when he awoke and found that pulsation had ceased in the aneurism. The limb was cold below the knee, and œdematous; and though the pain of the previous day was better, it was not gone. On examining the aneurism it felt hard, and was free from pulsation. He was subsequently discharged cured.

I am inclined to think that coagulation commenced here after the first flexion; that the deposit of coagulum, after a few hours, increased rapidly, as indicated by pain, which culminated in intensity as the sac was solidified. There may have been a clot detached which plugged up either the proximal or the distal orifice; if so, it took place at the final exacerbation of pain, when pulsation ceased, for I certainly judged the contents when I bent the limb to be fluid.

The verification of the intense pain that occurs when the blood-current is forced suddenly into narrow collaterals, or at the supreme moment when the contents of the sac are solidified, was here very conspicuous.

To ask, for a few minutes, the judgment of a skilled assembly, such as this, on the probability of applying pressure with success to the actual sac of an aneurism, would appear to be returning to the pre-Hunterian period; and yet, had the theory by which aneurisms are cured now been fully comprehended then, I can have little doubt that the necessary deposition of fibrin would have been brought about in many instances that otherwise signally failed.

I entertain the opinion that compression of the sac ought to be used more frequently than it is now. The principle of this proceeding is exactly the same as flexion: we want simply to alter the relations of the laminated fibrin to the cavity of the aneurism, so as to bring about a further deposition of fibrin on the projecting surfaces of any of the displaced laminae. The pressure need not be continuous. It should be very gentle. It need not, even, be distributed uniformly. But it must ever be borne in mind that if it be carried to such an extent as to empty the sac, and to press one wall against the other, then a cure cannot occur. The very conditions under which a cure is possible are here ignored. Blood must pass through the sac. It must not pass through too rapidly; and I now think that this would be facilitated by gentle pressure being made on the artery below the aneurism.

In March, 1857, I visited D., aged 67, an active sportsman and farmer. He had an aneurism, a month old, of the right external iliac artery, just above Poupart's ligament. It was somewhat fusiform in shape, measuring three inches in length by one and a half in breadth. There was no bruit. I failed to arrest the circulation through the aneurism by making pressure on the artery above; but I found I could greatly limit the current by making pressures on the sac itself. The question of an operation being raised, I advised that, as a ligature could hardly be applied to a sound artery other than in the course of the common iliac, and bearing in mind the vicinity of the bifurcation, no operation should now be performed, but that Dr. Carte's compressor, under careful management, should be applied to the sac itself. Accordingly, under my directions two senior students (the late Mr. Dennis Moore, of Walsall, and Dr. Neal, of Birmingham) remained with the patient. The treatment extended over a period of six weeks. During the first fortnight little good was effected. Then for eight consecutive days pressure was applied, on an average of seven and a half hours per day. The pressure effectually retarded the circulation—nothing more—and was never applied for more than three or four hours at a time. Consequently the patient was not wearied, and had undisturbed nights. There was now a complete interval of nine days, during which no pressure was applied, the aneurism being firmer and with less pulsation, and he was allowed to move about in his room. Then followed nine days of treatment, averaging six hours and a half per day. From this time the aneurism ceased to pulsate, and the patient gradually resumed his ordinary avocations. He is yet living, in his eighty-third year, active and well. In December last (letter from Mr. Earlam, of Abbots Bromley) the remains of the aneurism were represented by an indurated enlargement about the size of a chestnut.

I venture to think that even Dr. Macnamara will give me credit for having studied O'Bryen Bellingham (*Observations on Aneurism*, London, 1847) to some purpose, who, happily for my patient, published his observations in the January of this very year.

Reduce the force and volume of the blood current by any carefully considered measures, and we follow out the reasoning of Brasdor and Wardrop in the distal ligature; a reasoning which is rendering amenable to the treatment of internal aneurisms hitherto beyond surgery; a reasoning that has the authority of nature's own proceedings to recommend it, from the fact that it is more or less identical with the mode in which the so-called spontaneous cures are brought about.

I own, this case—unique as it is in this situation—has always been in my mind, on the discovery of any fresh instance of aneurism. It serves to confirm the soundness of the remark, that in proportion as the true method of curing aneurisms has been fully understood—that is, the gradual lessening of the blood current to final and complete coagulation in the sac—so have the means whereby this has been brought about, become simpler and more safe.

The occurrence of these cases led me to the attentive consideration of the facts, as they are at present before us, connected with the purposed displacement of the contents of the sac of aneurism, in the hope of plugging up either outlet:

and the case of M. happened when a subclavian aneurism (a) was under my notice in another ward, about the treatment of which I was—to say the least of it—previously undecided.

It seemed to me so impossible to limit the degree of force, short of extreme hazard, in the method originated by our distinguished *confrère*, Sir William Fergusson (*Medico-Chirurgical Transactions*, vol. xl, 1857); and I was not reassured by perusing the cases which he has recorded, or those of Mr. Pollock (*Op. cit.* p. 45).

I cannot but regard the treatment by manipulation to be based on exactly similar principles to those on which the methods I have just alluded to are founded. No forcible pressure to detach fibrinous laminae, in my judgment, ought to be used; as the result would be the almost certain separation of small portions of the clots, which would be carried into circulation, and would eventually plug the smaller vessels, causing symptoms according to the functions of the parts which the plugged vessels supply. For I must own I have not been able to see how these clots could be located at either outlet, to be fixed by arrangement, as it were, at a spot where it is simply impossible to be assured that they could effect a lodgment. All that is necessary is, that the aneurism should be gently manipulated, so that the laminae of fibrin in its interior should occupy a different position to that which they had previously held with reference to the two orifices of the sac; and in order that the blood should not be allowed to pass out of the sac too freely, if I have an opportunity, I shall endeavour to compress the distal artery in accordance with the principles I have been advocating.

B., 32, a former Lifeguardsman, was admitted into hospital October 20th, 1870, with aneurism of three months' duration, in the second and third parts of the right subclavian. It was as large as a hen's egg, and accompanied by bruit, and by dilation of the axillary artery. He stayed a month, during which time iodide of potassium was freely given; and then, frightened at the idea of an operation, he suddenly left. On January 20th, 1871, he was admitted again. The aneurism seemed firmer, giving me the impression that fibrin had been deposited. From February 10th to 14th, the sac was manipulated, night and morning, for a few minutes. The proceeding was one of the utmost gentleness and regularity, and consisted in making pressure with the thumb and finger, so as to slightly approximate its fibrous walls, and, whilst thus limiting the circulation, probably rendering the clot surface somewhat irregular, and promoting the tendency to deposit already commenced. On the 11th, pulsation was much weaker. On the 14th it ceased altogether. There was no brachial or radial pulse below the aneurism; and he complained of pain, extending downwards from the aneurism to the iliac region. This was constant, severe, and of a numbing character. There was no constitutional disturbance. During the following days the collateral circulation about the clavicle and shoulder developed itself; and especially noticeable was a large transversalis colli crossing over the aneurismal sac. On April 17th, he left for the Sanatorium, the sac being small and hard. Since this time he has pursued his business as hawker, travelling all over England. I examined him, and so did my colleagues, as recently as the 29th of June, sixteen months after the cure of the aneurism, and I noted the following facts: A little induration marks the site of the aneurism; the axillary artery and upper part of brachial can be felt, cord-like, as far as insertion of coraco-brachialis—here pulsation begins, and can be felt, feebly, in the radial at the wrist. He is himself excessively thin, but well and hearty.

The absence in this case of any symptoms of paralysis during the four days in which the sac was manipulated, justifies the inference that no clot at least passed into the cerebral circulation, and I entertain myself the conviction that the cure was brought about by a steady process of lamination, rather than by a detachment of a clot, happy enough to fit into either orifice of the aneurism.

I have now to call your attention to what I believe to be a not uncommon result of the cure of aneurism, after it has been effected for some time; I mean the formation of varicose aneurism or aneurismal varix. I shall first relate two cases. In 1844, my late colleague, Mr. Amphett, tied the superficial femoral for an aneurism of the artery as it enters Hunter's canal. The patient was aged 41, and a soldier. There was nothing unusual at the operation, and the ligature was thrown off on the nineteenth day. Ten days subsequently, there was

(a) Pollock records three cases of direct compression applied successfully to subclavian aneurisms.—*Guy's Reports*, vol. xvi, p. 63.

arterial hæmorrhage from the seat of the ligature. This recurred in ten days, and a third time in fourteen. Pressure on the arch was used, and the patient recovered. He remained well for upwards of three years, when a tumour formed at the seat of operation, which was evidently, an arterio-venous aneurism. With this coming under the care of my colleague, Mr. Baker, (our President), he died with a drunken pleurisy, just five years from the date of the operation. I was fortunate in being able to dissect his vessels. The femoral artery had formed an aneurism at the seat of the operation as large as a hen's egg, and the femoral vein communicated with the artery by a large opening. The former aneurism was cured, and the artery between it and the seat of the ligature was impervious.

M., 50, a soldier, syphilitic and intemperate, became the subject of an aneurism of the upper part of the right posterior tibial artery. Pressure was made over the artery on the pubic arch, for three weeks; on it, below, for nine months. The aneurism was cured. Ten months afterwards, an arterio-venous communication formed at the chief seat of pressure, and the patient died in about a year and eight months subsequently. I had the opportunity of minutely examining his body, and I came to the conclusion that pressure on the pubes induced varix in the femoral vein, at the situation of the saphenous opening; that this subsequently, sustaining pressure, enlarged and became adherent to the artery, and finally, by a succession of changes, readily comprehended, between a diseased artery and a diseased vein adherent to each other, ending in establishing an aneurismal varix.

At the time when I published this case, which was done at considerable length in the *Medico-Chirurgical Transactions* for the year 1861, I attributed the results merely to the injurious effects of long-continued instrumental pressure, producing morbid changes around and between the contiguous vein and artery; and I was inclined to quarrel with Bellingham's remark (*Medico-Chirurgical Transactions*, p. 12) "That no morbid change of any kind takes place in the artery or vein at the site of instrumental compression." Subsequent reflection, however, and an attentive study of the preparations, have led me to seek a different explanation. Thus, in consequence of the diseased conditions and diminished elasticity of the arterial walls, which almost constantly exist in all arteries above the seat of an aneurism, the velocity of the blood-movement is considerably retarded. It is evident that this retardation must be materially increased by the obstruction at the seat of ligature, or the seat of long-continued instrumental compression. The immediate consequence of this retarded velocity is an increase in the lateral pressure. This dilates the diseased coats of the artery into an aneurism, which—by the usual processes of pressure, absorption and disintegration—opens into an adjoining vein. Sometimes, as in the second case I have adduced, the opening is effected directly into the vein without the previous formation of an aneurism—and the vein subsequently becomes varicose by the passage of arterial blood into it.

(To be continued.)

AN ADDRESS

DELIVERED AT THE OPENING OF
THE SECTION OF MIDWIFERY.

By EVORY KENNEDY, M.D.

Late Master of the Dublin Lying-in Hospital; President of the Section.

As I understand, it is the duty of your Presidents to open each section of the British Medical Association with something of an address. It occurs to me that, in place of occupying the valuable time of so many of my *confères* with an historical analysis of the progress of our branch of medicine—the usual stock subject of all introductory lectures, and one on which you are all very likely more competent to descant than myself—I might possibly occupy your time more profitably and pleasantly by giving you a few cases of not very ordinary occurrence which I have selected from my notebooks. Be not alarmed. I shall not weary you with detail in these brief *excerpta*, but merely touch the salient points of interest in each case.

CASE I. *Fœtal Femur embedded in Uterus*.—A lady was brought to me from the country, anæmic, wasted, and with a countenance expressive of pain and suffering. She had a constant foetid vaginal discharge, purulent, and occasionally sanious. She was said to have miscarried a year before. She complained of pelvic distress, with lumbar pains and frequent micturition. On vaginal examination, the uterus was found about double its natural size. The os was slightly patulous, and a solid hard resistance was experienced on introducing the finger. The os was gradually dilated with a two-bladed uterine dilator constructed for the purpose, and a bony substance was distinctly felt, traversing the neck of the uterus at the junction with the body of the organ. This was so deeply embedded in the walls of the uterus, that neither extremity could be dislodged. I introduced a pair of small beaked bone forceps, constructed for the purpose, broke the bone across, and extracted piecemeal the femur of a fœtus of about four months' development, which had been all the time embedded in the walls of the uterus, which was converted into an abscess by the presence of what should have been its natural occupant, thus forming an unnatural nidus in its walls in place of its cavity. The discharge subsided; and the lady recovered her usual health; but the look of health was never quite restored. She, however, bore children after an interval of some years, and the uterus appeared to have quite regained its normal condition.

CASE II. *Excision of part of Neck of Uterus*.—Dr. Kitson, of —, brought a patient from the country, suffering from ulceration of the os uteri. The neck was enlarged considerably, and elongated, the ulcer, which impressed us both as presenting all the characters of malignancy, occupied about one-third of the neck. It had taken a rapid course, bled at intervals freely, and upon the slightest touch, and was attended with pain, sleeplessness, and marked constitutional disturbance. It was, however, circumscribed and limited to the part ulcerated; the remainder of the neck and os being healthy to the appearance and touch, although larger than natural. The lady had borne children. The part of the neck engaged extended from the posterior along the left side of the os, and the diseased structure appeared to occupy the entire substance of the wall. Under these circumstances, the case promised little or nothing from the application of the ordinary caustics, and the choice appeared to lie between the free application of potassa fusa and excision. The latter was determined on; first, because of the limited extent of the part engaged; secondly, because of the apparent malignancy; thirdly, from the difficulty of destroying by the potass the whole diseased structure, without extending its action to the adjoining vital parts. On the other hand, the diseased structure came well within our view; the neck was long, affording facilities for the use of the knife. The patient was placed on her back. The vaginal wall and labia were distended by my four brass tractors, firmly held by Dr. Hans Irvine, and Dr. Kitson. An ebony spatula, nine inches long, and half an inch broad, was introduced and placed within the os. This I held firmly in my left hand, whilst I introduced the scalpel which I now exhibit, which, you perceive, has a handle seven inches long, while the blade is scimitar-shaped. Cutting from without inwards towards the resisting spatula, commencing near the point of junction with the neck and body of the uterus, above the central part of the diseased structure, by two diverging incisions Λ , a triangular section was removed. I was prepared to draw the uterus down with the double tenaculum; but this was unnecessary, from the perfect manner in which my assistants used their tractors. This allowed me the assistance and security of the spatula to cut upon. It has occurred to me that, in a case where excision is preferred, and where the facilities I describe do not exist, the spatulum might be armed on the reverse side with two hooks, when it would perform the double office of uterine tractor and spatula, as necessary. The vagina was simply plugged with Ruspini's styptic. There was scarcely any hæmorrhage. The patient

recovered speedily and perfectly, and in about two years afterwards conceived and carried a living child to the full period. Her labour was easy and natural; and I had an opportunity of examining her at an interval of several years afterwards, when she was quite well, and the uterus, with the exception of the loss of a portion of the neck, was perfectly sound.

CASE III. Portion of Placenta thrown off in Pregnancy.—A lady, in the seventh month of her fifth pregnancy, was seized with hæmorrhage, ascribed to over-exertion. There were no labour pains. On examination, a portion of the placenta was found protruding through the os uteri. The hæmorrhage continued for several days, but to no serious extent, and still there was no labour. At length, fœtid grumous discharges, mixed with a little blood, occurred, attended with sense of downward pressure. The portion of placenta descended lower in the vagina; its connection with the interior of the os separated; and I removed it with very little assistance. As no increase of hæmorrhage occurred from this, I thought it unnecessary to plug the vagina. The hæmorrhage and discharge ceased, and the patient went on without any inconvenience, except the precaution of keeping the horizontal position for six weeks longer, when she was delivered of a living boy apparently at or near the full time. The edge of the placenta that remained could not be felt near the os, and the portion that came away consisted of the vascular structure without the reflected membranes. There was no discharge of liquor amnii until the labour set in.

I have already had the honour of calling your attention to some of the more rapidly destructive of puerperal diseases in a paper read for me, in my absence, by your secretary, at your Dublin meeting, under the head of puerperal fever. It is now my intention to allude briefly to other forms of blood-poisoning, but more especially to puerperal arthritis and puerperal gangrene, premising that, when this disease shows itself, it is usually most rapid and unsparring in its onslaught, and no tissue in the body escapes its ravages.

CASE IV. Destructive Inflammation of the Eye, combined with Arthritis.—Bennett was delivered of her first child after a labour of nine hours, on June 14th, 1838. On the 16th and 17th, there was abdominal tenderness, with a quick small pulse. She was leeches. On the 18th, her countenance was anxious and shrunken; pulse 140, small. On the 19th, sudden inflammation of the right eye set in; the conjunctiva and iris being engaged. Leeches were applied and blisters to the temples. Mercury was given. On the 21st, she was salivated. The whole globe of the eye appeared prominent with serous infiltration beneath the conjunctiva. All the tissues of the eye were engaged; the sclerotic was very vascular, the cornea prominent, the aqueous humour turbid, the iris hardly discernible; there was total loss of vision. The conjunctival vessels were freely scarified. This evening, inflammation of the wrist set in, with erythema of the back of the hand. Excitement and delirium were present. On the 22nd, the other wrist became engaged; her countenance was shrunken and excited. Pulse 125, small and thready. The wrists were treated with solid nitrate of silver. She sank, and died on the 24th. At the *post-mortem* examination, effusion of blood was found on the right side and posterior lobe of the cerebrum, and a small quantity between the arachnoid membrane and the pia mater on the left side. The brain in other respects was healthy; there was no fluid in the ventricles. The right eye was much suffused; the conjunctiva very vascular, the cornea perfectly opaque. On extracting the eye, some pus was found round the lacrymal sac. On cutting down on the carpal bones, a quantity of pus was found in the sheaths of the tendons, unconnected with the joints. Pus was found in the vessels of the broad ligaments of the uterus; but there was no fluid in the cavity of the abdomen.

I would now call your special attention to the drawing which I exhibit to you as a type of disease known as sloughing of the vagina, but which would be more cor-

rectly designated as lying-in hospital gangrene; and also to a group of cases occurring in puerperal women as the result of their state and condition, but which are now clearly established as prevailing so commonly in great lying-in hospitals, and so rarely out of them, as to stand in relation of effect and causation with the locality of their delivery. As in surgical hospitals, so in lying-in hospitals, these cases are ascribed to hospital or poisoned atmosphere.

These cases generally occurred in groups. For instance, in April, 1837, four occurred in the Dublin Lying-in Hospital at the same time, not one of which recovered. On the 6th of June of the same year, complicated with arthritis of the elbow-joint; one in October, and one in November—all being fatal. Another at the same time was complicated with erysipelatous inflammation of the buttock, followed by abscess and inflammation of the elbow, sterno-clavicular and shoulder-joints; and yet this woman (Keating), the drawing of whose disease I exhibit to you, struggled through all this and recovered, after two months of as acute suffering, from the number of joints consecutively engaged, as ever I witnessed. Free incisions were made into the buttock, with escape of pus. The sterno-clavicular joint suppurated, and an incision was made, but the inflammation of the elbow and shoulder-joints yielded to the free application of nitrate of silver and potassa fusa. On the 8th of December, another fatal case occurred. This case was complicated with slight peritonitis; and the *post-mortem* examination disclosed a peculiar lesion of the peritoneal surface of the uterus at the junction of the neck and body anteriorly, which I have rarely observed, but which of itself I esteem a very fatal occurrence.

CASE V. Puerperal Arthritis—Erosion of Cartilages of Elbow, Hip, and Ankle Joints.—Kenny, three weeks delivered after a difficult and protracted labour, was awakened from sleep in the night by an acute pain in the left groin. In the morning, she observed a swelling in the middle of the thigh, which at the end of two days had completely engaged the entire limb. The pain became less acute as the swelling increased, but never entirely subsided. Some days subsequently to the swelling of the thigh, she was seized with violent pain in the elbow, but did not perceive any swelling. All these symptoms progressively increased, notwithstanding frequent leeching, stuping, poulticing, opiates, and mercury. She was admitted into hospital on January 28th, 1829; and, on the 30th, there was an obscure sense of fluctuation over the outer third of the thigh. An incision was made into it, but no pus followed. On February 3rd, she had a severe rigor; and on the 4th, she died comatose. A *post-mortem* examination was made twelve hours afterwards. The cellular tissue throughout the entire thigh was filled with gelatinous lymph. An extensive abscess extended from nearly one extremity of the thigh to the other, between the periosteum and muscles. The muscles were pale and flabby, and appeared much softer than natural. About one inch of the upper part of the femoral vein contained pus; its inner tissue was vascular, but did not appear to have lymph upon its surface. The synovial membranes of the hip, knee, and ankle-joints, were filled with puriform matter. The cartilage covering the bones of the hip appeared healthy; whilst that covering those of the knee and ankle was in part removed by absorption, particularly in the ankle, where scarcely a trace of cartilage could be detected. The uterus was vascular, and inclined towards the left side. The lymphatic glands along the iliac vein were enlarged and vascular. The cartilage was removed altogether from the extremities of the bones forming the right elbow-joint. The viscera appeared healthy.

CASE VI. Puerperal Arthritis: Sterno-clavicular Articulation and Buttock engaged; Recovery.—Keating was delivered in November, 1837, of a still-born child, after a labour of thirty-five hours. There was some sloughing of the vagina, but not considerable, with a good deal of tympanitis of the abdomen and irritation, which were relieved by turpentine followed by opium. On the eleventh day, there was an erysipelatous state of the right

elbow, which had been, she stated, painful three or four days previously. She was treated with nitrate of silver locally, and sulphate of quinine with hyoscyamus constitutionally. On the 12th day, she was attacked with erysipelatous inflammation of the left buttock (the elbow having become improved), which was also treated with the caustic and with quinine. On the sixteenth day, there was an appearance of pointing in the buttock, and an eschar was made with potassa fusa. There was this day noticed some tenderness in the right iliac region. On the seventeenth day, she complained of the left sterno-clavicular articulation, which was swollen, red, and painful; it was scored with caustic, the other treatment was continued, and wine was given. On the twentieth day, a fresh eschar was made on the buttock, through the slough consequent on which a lancet was passed on the twenty-ninth day, giving exit to matter of a healthy character. The swelling of the sterno-clavicular articulation continuing, with decided fluctuation and uterine pain, there being present also great constitutional disturbance, an opening was made on January 11th, 1838, and exit given to healthy pus. She gradually improved after this, and left the hospital. There still remained some swelling, but the opening had healed.

I can conceive what I term lying-in hospital gangrene to occur out of hospital; yet, after a protracted and sufficiently extensive opportunity in my own practice and in consultation, I cannot tax my memory with ever having met with a case of it out of hospital. Would that I could make the same statement of my experience in hospital! It occurs in isolated cases, but more frequently prevails in groups of cases, when a tendency to its congeners—puerperal fever, erysipelas, arthritis, and peritonitis also prevails. It is usually the effect of long continued pressure or lesion, or of the force used by the application of instruments in forced deliveries. Indeed, so constantly is the disease observed to occur as the result of these agencies, that they may be fairly looked upon as the exciting or determining cause, and the disease classed as a traumatic affection, and treated accordingly. This is so well understood by the observant hospital physician, that he looks with dread to the occurrence of any lesion when the hospital is in an unhealthy state; and, for the same reason, hesitates to perform the simplest operations, lest they be followed by this affection—operations that, in a healthy state of the hospital, would not cost him a thought.

I hold that the congregation of a number of patients in common chambers generates what we term a hospital atmosphere; that this hospital atmosphere is, or more properly becomes, a poison; that, by a persistence in the causes of its production (with which we shall presently deal), it undergoes a process of what may be termed cumulation, pervading every part of an enclosed building, until it eventually arrives at a stage which we may term saturation, when the whole hospital is charged with a poison capable of seizing upon those who are susceptible in its influence, or who are in what we term a state of receptivity.

Now, from this it will be seen that, by crowding patients in a hospital, we are actually exposing them to a new disease generated by the very means we adopt to cure them of the disease under which they chance to labour. But, unfortunately, the new disease is generally one most fatal in its character, as few there be who survive it.

The characters or phases of the hospital disease vary under the different circumstances of the victims susceptible to it. Thus one may be attacked with blood-poisoning or empyema; another with erysipelas; a third with hospital gangrene; and a fourth with metria or puerperal fever. The laws which regulate the habits of this family of zymotic disease are perhaps best arrived at by a study of the last named poison, as, in its occurrence in our great lying-in hospitals, where it principally commits its ravages, it is less exposed to disturbing influences, and consequently pursues its own natural course free from interruptions and complications.

Out of a 111 years, for which the great Dublin Lying-in

Hospital has been established, it has been haunted by puerperal fever 93 years. For 12 years it has been comparatively, and only for 8 years has it been totally, free from this fell disease. The deaths of those admitted for the last year amounts to 1 in 33. Let us remember that in 3 small cottage hospitals in Ireland, in which accurate tables have been kept (Kilkenny, Newry, and Waterford), we find that the mortality has been 1 in 282. On the comparison of these two proportions, the conclusion is inevitable that 8 out of 9 patients have died in the Dublin Lying-in Hospital who would not, in all likelihood, if they had taken refuge in the cottage hospitals, which were comparatively free from the hospital miasm or poison that prevailed or lurked in the great unhealthy hospital.

A fatal error, into which we are prone to fall, is the confounding epidemic and endemic disease; and the amount of loss of life that has occurred from this error I believe to be incalculable. This will be easily appreciated when we state that what, in strictness, we should call true epidemic diseases, are unavoidable; whilst the latter, or endemic diseases, are, with rare exceptions, preventable and perfectly within our control. True, they may be convertible; but this makes the distinction the more important, in order to prevent their extension or fixture.

The contagious nature of hospital miasm is now beyond question; as also that of most of those modifications of hospital zymotocene with which we are familiar, especially metria and erysipelas.

Having satisfied ourselves that a poison is generated by the mere crowding of numbers of patients into a common atmosphere, and also that this poison spreads by contagion, the next principle or law we require to establish is that this poison is cumulative, or developing in its quantity, commencing with a single poisonous emanation and increasing in its quantity until the atmosphere, walls, floors, and furniture become imbued or charged with it. Unfortunately, as yet we are unable to detect this miasm or poison and display it by its sentient properties; but of its existence we cannot have the slightest doubt, from its effects, from its laws, from analogy, and especially the spread of diseases by inoculation and contact.

But why should the hospital wards ever be free from hospital miasm and these fatal results, if all this be true! This is a question to be answered by the law upon which we now dwell—cumulation. The ordinary epidemic disappears; having, as we say, worn itself out. This it does in hospital as out of it. Precautions are taken; patients zymotically affected are separated; ablution and ventilation are carried out; admissions are refused; the wards are emptied; and the hospital becomes healthy. Weeks, months, and longer, pass over before the poison again shows itself. The cumulative process, however, is in steady operation; and at an uncertain period the poison again shows itself, and snatches up its victims. The same measures of precaution are taken to banish it, and with the same results. But it does not rest here, as has been abundantly proved by the history of our great hospitals. When the cumulation has gone on repeating itself again and again, a further stage, or that which I shall denominate the state of complete saturation is arrived at, and then the hospital becomes the fixed *habitat* of the poison.

The death of the consumptive costermonger is not to be placed in the category of the victims to hospitalism. It has its analogue in the dog slain in the Grotto del Cane for the instruction of his slayers, by holding him so close to the surface of the deadly cavern that he can only inhale mephitic gas. Nor, indeed, is it only in St. Pancras that we have this going on. Have we not our No. 11 wards and grottoes in nightly operation for the benefit of the upper ten thousand in the West-end *réunions*? Witness the pallid and poisoned state to which our belles are reduced, at the end of the season, from breathing mephitic and animal-poisoned air for several hours nightly, with their lungs at nearly as great a disadvantage as the costermonger's, by tight lacing and waltzing. The Black Hole of Calcutta and the middle passage rendered our fathers familiar with the more immediate effects produced from a

number of people breathing and rebreathing the same atmosphere; and its more gradual effect in the production of jail-fever, grappled with by Howard in his mission of mercy, has reached us as a matter of history. We were in hopes that the labours of Boswell Reid and Arnott had exposed the defects of ventilation and directed a remedy. But the enormities occasionally cropping up from neglect in this respect shows that much remains to be done. Dr. Farr, in a paper lately read at the Leeds Conference, pointed out the want that exists of an authoritative organisation charged with the ministry of public health. As it is, what is every man's business is left undone. When will our legislators waken up from their piecemeal attempts at sanitary improvement, and grapple with this great subject as it demands, and as the well-being of the community requires?

The fact is that, when the poison is generated, crowding or the cohabitation of patients in a state of receptivity secures its spread. A process of cumulation of the contagion or poisonous element occurs; and when this arrives at the stage of saturation, outbursts of erysipelas, phagedæna, gangrene, pyæmia, and metria occur; the patients are attacked wholesale; and the diseases become, as we before stated, endemic or fixed, and continue to haunt the hospitals, be they surgical or obstetrical.

Now that the blot has been hit, it requires no great philosophy to meet the difficulty. Simply cease to crowd such patients into common buildings under the same roof. All the advantages of an asylum can be afforded whilst segregation is secured, and facilities for Medical instruction is preserved to the schools. The substitution of cottage-hospitals for these great hotbeds of contagion should be insisted upon in all future arrangements for housing cases liable to endemic poisons. The term epidemic should be applied in its true meaning. These large surgical and maternity hospitals, in which metria, erysipelas, and pyæmia have committed such havoc, should be either applied to purposes compatible with the safety to human life, or so altered in their construction as to isolate each ward from the common atmosphere now pervading the whole hospital. This may be very simply and inexpensively accomplished by opening separate entrances into each ward direct from the open air. In the existing hospitals, the communications with the common hall should be built up, and the same system carried out in the upper stories by opening the ward doors on flying galleries. The lifts and stairs should be placed outside of the building; the existing halls and passages being still retained for the staff, and affording an approach to the respective storeys, but no covered approach or communication of any kind allowed to remain between these and the wards. By these simple expedients, and limiting the number of beds to three in each ward, it is probable a large saving of human life would result, and hospitalism become, like jail-fever and small-pox, a thing of the past. Pity the founders of the great hospitals so recently erected had not applied our dear-bought experience in their magnificent constructions. The sooner these altered arrangements are made in such great palatial institutions as St. Thomas's and the Leeds Hospitals, as well as the Maternities and our other great charities subject to erysipelas, pyæmia, and phagedæna, the sooner will the insidious approaches and the fell ravages of our common enemy, hospitalism, be subdued.

Stow, in his *Survey*, mentions, in speaking of the King's Bench Prison, that the great mortality that occurred there in the six years preceding 1579 was produced through a certain contagion called "The Sickness of the House." Those learned physicians who uphold the crowding in large hospitals, and imagine they can meet the difficulty by disinfectants, I would refer to the simple experience of that benefactor of our species, John Howard, as conveyed in his preface a century since. He says: "I guarded myself by smelling to vinegar while I was in those places. This I did constantly and carefully when I began; but, by degrees, I became less attentive to these precautions, and have long since entirely omitted them." John Howard discovered and carried out the best means, on

true scientific principles, of disposing, once and for ever, of "the sickness of the house." If the obstinate hospital crowders would take example by him, and meet, as he did, crowding, the cause of "the diseases of the house," and, as he did, remove them, they would speedily produce an equally satisfactory result, and, like Howard, give up their futile attempt to meet the case of dealing with emergency by "smelling to vinegar."

CASE VII. *Lying-in Hospital: Gangrene.*—Catherine Barnes was delivered by crotchet, after a tedious labour, of her first child. She had one fit of convulsions on entering the ward, and was treated with tartar emetic. There was no return of convulsions. Extensive sloughing of the vagina showed itself the day after delivery, with great debility and exhaustion. Tympanitis and delirium occurred, and she gradually sank, and expired on the fourth day after her delivery. The appearances exhibited in the plate presented themselves. A small quantity of limpid serum was observed in the peritoneal cavity. The whole vagina and the lining of the uterus were in a state of slough. The os uteri was jagged and disorganised; and there was serous infiltration underneath the pelvic cellular membrane.

These cases are sometimes attended with hæmorrhage. For instance, in Murphy (October, 1837) there was lingering labour with slow dilatation. She was treated with tartar emetic and ipecacuanha injections. She was delivered naturally on the 17th, but with laceration of the perinæum, of a still-born male child. Sloughing was perceptible, with rigors and prostration. Hæmorrhage from the vagina set in as the sloughs were separating, on the 24th; and she sank on the 25th.

In Black's case, the drawing of which I here exhibit, she had tedious labour, followed by sloughing inflammation of the vagina and external parts, of erysipelatous character, spreading from the vulva to the buttocks and back. She sank from exhaustion after a long struggle. In addition to the appearances here represented, the omentum was found adherent to the pelvis and uterus: and an abscess in the walls of the latter organ opened into its cavity.

AN ADDRESS

DELIVERED AT THE OPENING OF
THE SURGICAL SECTION.

By SIR W. FERGUSSON.

In my younger days, the surgeon had few sources of alarm greater than that of inflammation of veins, phlebitis as the term went. Abernethy had added greatly to his reputation by his celebrated essay on the occasional evil consequences of the operation of venesection. Every good surgeon did his best, by suggestion and action, to prevent injury to veins during operations; above all, we were restricted from putting ligatures on veins, such a step being deemed wellnigh fatal, although there was ample proof that some thirty or forty years further back our predecessors were by no means nice in excluding veins from nooses which were intended for arteries chiefly. It is doubtful if their operations were less successful than ours. At all events, we have so far changed in regard to the probabilities of phlebitis, that we, in the present day, think as little of applying ligatures to veins as to arteries, when there seems need, and we take all sorts of rough liberties with them when in a varicose state. True, we have a modern bugbear in the shape of pyæmia, for which the veins are greatly blamed, a disease about which there prevails more questionable physiology than common sense should admit. This subject is closely allied with what was called secondary deposit in former times, and this last named condition was itself closely allied with Hunter's views and theories regarding inflammation. Any one who

is watching the spirit of the times, must see that there are strange views afloat regarding Hunterian doctrines, which seem totally to ignore our great surgical philosopher—most notably in this respect, that what Hunter thought was developed by Nature from within, is now alleged to have origin in external influences and agencies which have no dependence on what has heretofore been considered life and life-like action within the frame.

One of the grandest features in surgery is its precision. This applies more to the art than to the science of our department, and one fact is worth a volume of theory. That a new operation has been added to our list of operations—that at the ankle, as developed by Syme and Pirogoff, is a fact that surgery may justly be proud of. As much may be said regarding amputation at the knee, the most recent and greatest stimulus having been given in that direction by one of the foremost of British surgeons, our respected member, Mr. Carden, of Worcester. I maintain it as a fact, that even amputation itself, the direst of all surgical operations, has been largely superseded by more judicious methods of treatment. It seems a fact, that statistics of amputations are no longer so fashionable as they once were, because it has been proved by fact that a more limited use of the long knife might have greatly diminished the numbers of those operations which have been justly called the *opprobria* of surgery.

When ovariectomy was first propounded, it was little else than a theory—a rash visionary scheme for notoriety; but, thanks to the well-directed efforts of Clay, Brown, Wells, Keith, and a host of others, the proceeding is a well established fact, which ranks among the best and safest efforts in surgery to save human life.

Anæsthesia is another fact in modern surgery; perhaps, in reality, the most surprising of all. We are often told that the facts in real life are more surprising than those which the novelist delights to depict in fiction; and, in my opinion, the fact of anæsthesia, by whatever means it is brought about, by far surpasses all that has yet been done in regard to practical surgery.

Gentlemen, my mind has perhaps been naturally inclined to refer to "facts" on the present occasion, from the circumstance that, in my own professional career, I have been always more influenced by facts than by suppositions or questionable agencies; by the positive than by the speculative. I fear that it must be admitted that, despite all the skill of medicine from the earliest times to the present, the disease, stone in the bladder, must still be admitted as one of the "ills which flesh is heir to"—as a fact. We know it, however, as a fact, that our skill is such that we can combat that fact, and even assume the supremacy by surgically doing away with it. It is a matter of theory whether or not we can combat successfully with a diathesis to stone; but it is a matter of fact that we can combat manfully, aye, even successfully, with that painful enemy, when he once plainly shows his colours. Taking the surgical aspect of treatment, we can more readily, and with greater certainty, cope with this disease than with many others that come under the consideration of the surgeons.

It has been my fate, gentlemen, to have been largely engaged in this field of combat. Others in this country, of my own age, may have been more so; but, with the exception of Sir Henry Thompson's experience in lithotripsy, their labours have not been made public, or have escaped my observation. Whether my contemporaries in Britain have treated more cases of stone in the bladder than I have, I am not prepared to say; or, whether they have more proofs of experience than I can display, is also beyond my knowledge; but, anyhow, to add my humble effort to what may excite interest in this meeting of the British Medical Association, I have ventured to put on show the results of my personal work in dealing surgically with this fell malady of mankind. By a kind of prescience, as I may now call it, I, at an early period of professional life, kept, on behalf of my own surgical museum, or surgical taste, all that could serve to revive the memories of the past or illustrate the events of the passing day.

Throughout my professional life I preserved any stone or bit of stone that I could secure as a trophy of surgery, and now I have the honour of laying before the present meeting of this Association between 300 and 400 specimens of this disease which have been dealt with by my own hands. Every now and then patients or their friends have insisted on keeping what might be deemed as hereditary personal property, and occasionally specimens have fallen aside; but on the whole, I must admit, that my patients or their friends have humoured my fancies and given me free possession of the results of my surgical prowess. I exhibit the produce of between 330 and 350 cases of stone, personally treated by myself—about 200 by lithotomy, the rest by lithotripsy. The aggregate of stones removed amounts to nearly 500 in number. There may be others of my own time who can speak of larger numbers; there may be those who can show larger numbers of actual proofs of what they have done in this field of surgery, and I see with pleasure the valuable contributions made in this direction, especially by Messrs. Gutteridge, Pemberton, Baker, Pracey, Bartleet, Elkington, Freer, and Jackson, which add largely in my estimation to the value of your museum display.

Most of these specimens were exhibited years ago at the Royal College of Surgeons in London, when I lectured on the subjects of lithotomy and lithotripsy, but the time for their display was so evanescent that they attracted little attention, although at that date there was not a specimen of crushed stone by lithotripsy in the Museum. A feeling seems to prevail that there is no interest in a stone broken into fragments by the lithotrite, but if it has been cut into two by a saw, after its removal from the bladder, the cut surface is eagerly looked at. No doubt the interest here has reference to the chemical composition of stone, and possibly the nucleus, although the section does not invariably make that clear. In my estimation, the fragments in lithotripsy possess an interest equal, if not greater, in every respect to the cut or entire specimens. The chemical composition of a stone can be as readily made out from fragments as from sections; so also, as regards the nucleus; and, indeed, from these fragments we can often acquire a knowledge of a patient's constitution, as regards the tendency to the formation of stone, which we cannot in any other way. We can see how in some the fragments will lie in the bladder without change of surface much longer than in others. In one case we can recognise for days, even weeks, the fragments of an uric acid stone with edges defined and surface the same as when first broken; in another, we perceive how readily and rapidly new stone deposit occurs—generally phosphatic. Then, too, we can speedily appreciate the danger of neglect or carelessness after lithotripsy is once begun, for, in place of probably only one stone being present, there may, indeed there will, soon be many stones, for each fragment becomes a nucleus for fresh deposit, and this hastens on with greatly increased rapidity. Even the nucleus, always a centre of interest, may be as appreciable in the fragments from lithotripsy as when displayed by the saw. It has happened to me in a case of crushing, in a female, to be struck with the appearance of redness in many of the fragments; and on investigation the mystery has been revealed on confession, that the patient had been in the habit of tickling herself with a stick of red sealing-wax, a portion of which had broken off in the urethra and remained in the bladder. The fragments will be seen in the collection.

Again, I once was aware, in using a lithotrite in a male, that I had clutched something peculiar. On withdrawing the instrument, there was a black substance about an inch long between the blades. A surgeon present, who had been in charge of the case for years, immediately exclaimed, "Egad! this is the end of my gutta-percha catheter." A terrible revelation, for in the interim the patient had undergone prolonged treatment for chronic inflammation of the bladder, and had actually gone a voyage to Madeira in search of health.

I put as much faith as any man does in the chemical treatment, if I may so call it, of the diathesis of stone;

but when once a stone has formed (and in most instances it is so without marked premonitory warning), the "fact" of stone is established, and there may be room for doubt whether chemical treatment does not then make matters worse; for, whatever the quality of urine, the chances are that a nucleus being present, deposition of stone will go on with increased rapidity, equivalent to the increase of size of the stone. That there may be exceptions to this rule, I admit; and there are two stones in my collection from one bladder, which are so smoothly polished by attrition that the formation of more stone had probably ceased for many months, if not years, before they were removed.

I have referred, gentlemen, to the chemical treatment of stone in the bladder, chiefly for the purpose of ventilating a sort of heresy of my own—viz., that in our treatment of stone, and in our estimate of specimens of stone in our museums, the chemical composition has been improperly the feature most referred to as the one of the greatest importance. Stone in the bladder is essentially a surgical disease; it can be treated effectually only by the surgeon; and to him the size, or, I may call it, the circumference of the substance to be removed, possesses the most engrossing interest, whether he looks to his own mechanical work or the safety of his patient: for I hold it as a maxim, particularly in lithotomy, that the bigger the passage required for egress, the more difficult and the more dangerous is the operation. The *accoucheur* considers the size of the head, but does not trouble about its chemical qualities or composition. So should the surgeon the stone, both in regard to lithotomy and lithotripsy.

REGISTERED FOR TRANSMISSION ABROAD.

THE
MEDICAL PRESS AND CIRCULAR

is published simultaneously in London, Dublin, and Edinburgh, every
Wednesday morning. Price 5d. Post free, 5½d.

POST FREE TO ANNUAL SUBSCRIBERS £1 2 6
" IF PAID IN ADVANCE 1 0 0

* Post-office Orders and Cheques to be drawn in favour of—
A. A. TINDALL, 20, King William Street, Strand, London, W.C.
A. H. JACOB, Molesworth Hall, Molesworth Street, Dublin.
MACLACHLAN and STEWART, South Bridge, Edinburgh.

SUBSCRIPTIONS FOR FRANCE are received by MESSRS. BAILLIÈRE, Publishers to the Académie de Médecine, Paris—post free in advance £1 6s. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by MESSRS. WILLMER and ROGERS; Baltimore, by MESSRS. KELLY and FRET; Philadelphia, by MESSRS. LIPPINCOTT and Co., and Dr. BUTLER, post free in advance, £1 6s., about six and a-half dollars; or direct from the Offices in this country for the same amount, by the new Post-office Order system.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 21, 1872.

AUTUMN MANŒUVRES, 1872.

EACH regiment and battery of Artillery is to be accompanied by one Medical Officer. There will be one bell tent to each for the purpose of examination of men reporting themselves sick; there will be one trained orderly to each, a field companion constituting all the

regimental Medical equipment. Regimental and Staff Medical Officers will be employed in field hospitals; the following being the constitution of those establishments, namely:—

Head Quarter Staff.—Principal Medical Officer, Inspector-General James Fraser, M.D., C.B.

THE SOUTHERN ARMY CORPS.—Principal Medical Officer, Deputy Inspector-General J. M. S. Fogo; Staff Assistant-Surgeon W. Alexander; Staff Assistant-Surgeon P. W. Stafford.

Staff 1st Division.—Principal Medical Officer, Staff-Surgeon Major J. A. Thompson. 1st. Field Hospital.—Staff-Surgeon M. J. A. Woolfreyes; Assistant-Surgeon Owen Owen, 50th Regiment, and Assistant-Surgeon R. C. Lever, M.D., 7th Hussars. 2nd Field Hospital.—Surgeon-Major W. Peake, M.D., 88th Regiment; Assistant-Surgeon R. W. Forsayeth, 95th Regiment; Assistant-Surgeon R. H. Bolton, 3rd Dragoon Guards. 3rd Field Hospital.—Surgeon M. B. Tydd, 2nd Battalion 23rd Regiment; Assistant-Surgeon C. A. Atkins, 1st Battalion 7th Foot; and Assistant-Surgeon A. L. Malladen, M.D., 12th Lancers.

Staff, 2nd Division.—Principal Medical Officer, Surgeon-Major R. Gilborne, 6th Dragoon Guards. 1st Field Hospital.—Surgeon F. W. Moore, 2nd Dragoon Guards; Assistant-Surgeon W. H. Harman, M.D., 4th Battalion 60th Rifles; Staff Assistant-Surgeon E. J. Clarke. 2nd Field Hospital.—Surgeon A. Reed, 2nd Battalion—16th Regiment, Staff Assistant-Surgeon J. J. McCarthey, and Staff Assistant-Surgeon R. W. Lowe. 3rd Field Hospital.—Staff-Surgeon H. Titterton, M.D., Staff Assistant-Surgeon D. Murray, Staff Assistant-Surgeon T. G. Bolster, M.D.

THE NORTHERN ARMY CORPS.—*Staff of Army Corps.*—Principal Medical Officer, Inspector-General J. Fraser, M.D., C.B.; Staff Assistant-Surgeon G. Duncan; Staff Assistant-Surgeon J. White.

Staff, 3rd Division.—Principal Medical Officer, Staff Surgeon-Major G. A. F. Shelton. 1st Field Hospital.—Surgeon-Major B. Lane, 2nd Battalion 4th Regiment; Assistant-Surgeon J. Paxton, M.D., 30th Regiment; and Assistant Surgeon J. Bourke, 2nd Battalion, 15th Regiment. 2nd Field Hospital.—Surgeon F. S. G. Gunn, 99th Regiment; Assistant-Surgeon H. Harrison, 46th Regiment; and Assistant-Surgeon T. Steward, M.D., 90th Regiment. 3rd Field Hospital.—Surgeon W. H. Pollard, 2nd Battalion, 22nd Regiment; Assistant-Surgeon J. D. Milburne, 13th Hussars; and Staff Assistant-Surgeon E. Chandler.

Staff, 4th Division.—Principal Medical Officer, Surgeon-Major—Franklyn, Royal Horse Artillery. 1st Field Hospital.—Surgeon B. Burland, M.D., 13th Hussars; Staff Assistant-Surgeon J. G. Grant, and Assistant-Surgeon J. V. T. Malcolm, M.D., 9th Lancers. 2nd Field Hospital.—Surgeon O. L. Patterson, 1st Battalion 22nd Regiment; Assistant-Surgeon E. S. Lowe, M.B., 102nd Regiment; Staff Assistant-Surgeon A. W. Sheddon, M.D. 3rd Field Hospital.—Surgeon R. W. Jackson, 100th Regiment; Assistant-Surgeon A. A. Macrobin, M.B., 2nd Battalion Rifle Brigade; and Staff Assistant-Surgeon J. H. Reynolds, M.B.

The following notes in regard to some of the arrangements connected with the autumn manœuvres may, it is hoped, have an interest to the military members of the Profession, especially those employed in the field.

Surgeons, and other Medical officers ranking with field officers, are each allowed 80 lbs. of personal baggage, inclusive of bedding, and 22 lbs. cooking vessels for every three.

Each division is in charge of a Principal Medical officer, to whom 1 clerk and 1 orderly are attached. It has three field hospitals, namely, 1 per brigade; these being at the disposal of the Principal Medical officer.

The following represents the establishment of each field hospital, namely, 1 surgeon in charge, 2 servants, 2 horses, 1 bell tent; 2 assistant-surgeons, 2 servants 2 horses, 1 bell tent; 2 ward masters, 1 as clerk and compounder; 1 steward, 1 cook, 6 orderlies, 1 bell tent for them and Medical officers' servants. Each hospital

will in addition have the following bell tents, viz., 1 for the surgery, 1 for stores, 1 for office; marquees, 3 complete, or 2 with 2 ridge-pole tents; 2 for service for latrine purposes, 45 sets of bedding, 2 sets of Medical comfort boxes (per division), 2 sets "A" and "B" canteens for 25 each, 1 set of regimental comfort boxes for reserve medicines, 14 hospital bearers, 2 operating lamps, 1 field table, 1 chair (for the office), 8 water-buckets, 2 flag-staffs (20 feet long), 2 flags with Geneva cross, 1 water-cart, 15 ambulance waggons for each division, 2 general service waggons will be attached to each field hospital for tents, Medical stores, officers' baggage, &c., also 1 horse for the Medical field panniers. Tools will be issued to each hospital as under, namely, 4 spades, 4 pick-axes, 4 felling axes, 1 cross-cut saw (about 4 feet), 18 reaping hooks, 1 three-gallon oil-can. For each regimental Medical officer for the examination of the sick and isolation of particular cases, there will be allowed 1 bell tent, 1 water-bucket, 4 waterproof sheets; these being carried with the regimental baggage. One stretcher per regiment will be taken to the field. Straw will not be issued as bedding for men or horses.

Light.— $\frac{1}{2}$ gill of oil for each lantern, 1 dram wick for 8 gills of oil. Oil for hospital lamps is to be drawn on the certificate of a Medical officer that it is absolutely necessary.

The following is the field ration per man per day for men and officers, viz.:—Ordinary rations: 1 lb. of bread, or 1 lb. of biscuit; 1 lb. of meat, salt or fresh; extra issue of $\frac{1}{2}$ lb. cheese for men on outlying picket, or other difficult positions. Groceries: $\frac{1}{4}$ lb. of bread, $\frac{1}{2}$ oz. of tea, 2 ozs. of sugar, $\frac{1}{2}$ oz. of salt, 1-36 oz. of pepper. Stoppage, 1s. a day for officers.

Fuel.—3 lbs. wood, 2 lbs. small firewood, or 4 lbs. small turf sods, to every 36 lbs. of coal. The sick in hospital and hospital sergeants receive two rations daily on the certificate of the surgeon.

Forage.—14 lbs. oats, 8 lbs. hay. Large horses for draught receive 2 lbs. of oats in addition when requisite.

The daily field ration of men in hospital will consist of 1 $\frac{1}{4}$ lb. bread, 1 lb. meat, $\frac{1}{2}$ oz. of tea, 2 ozs. of sugar, $\frac{1}{2}$ oz. salt, and 1-36 oz. of pepper. This will be supplemented when necessary by Medical comforts. The daily stoppage for men and boys in hospital will be 10d.

Medical comforts as under will be placed in the field panniers of each brigade, and replenished when necessary, viz.:—No. 1 pannier: 1 bottle of brandy, 1 bottle of water. No. 2 pannier: 1 lb. of tea, 2 lbs. of sugar, 1 lb. of arrow-root, 1 lb. of essence of beef, 1 tin of cocoa and milk.

The following is a list of kit, equipment, arms, &c., carried by each infantry soldier in the field, viz.:—1 busby, 1 tunic, 1 serge trousers, 1 boots, 1 socks, 1 shirt, 1 braces (wearing them); 1 rifle, 1 sword, 1 waistbelt, 1 water-bottle, 1 braces for valise, 1 valise, 1 great-coat and straps, 2 pouches, 1 ball bag, 1 mess tin and strap, 1 pair leggings; ammunition, quantity not known as yet. In valise: 1 pair of trousers, 1 shirt, 1 pair of socks, 1 towel, 1 knife, fork, and spoon, 1 razor and case, 1 shaving brush, 1 small book, 1 brush, 1 blacking, 1 small box of shoe grease, 1 forage cap. If rations are carried, meat in mess tin, bread, &c., in valise. The weight of all the above is 33 lbs. 10 ozs.

The articles to be carried in the regimental *squad bags* are—the new tunic, new serge jacket, one pair of trousers

(serge or cloth). In the *bales*—1 pair of boots, or 2 pairs when sanctioned; 1 shirt, cotton; 1 pair of socks, 1 towel, 1 pair of mitts., 2 brushes, busby cover, black linen bag, 1 old serge jacket (if sufficiently good), 1 Bible, 1 waistcoat, for winter wear under the serge.

In reference to the personal clothing and equipment of the soldiers about to be employed in the manoeuvres, some points present themselves as deserving of attention on the part of regimental Medical officers. A few of these we will briefly allude to. As will be seen from the list above given, the men are unprovided with drawers, or at any rate supposed to be so. The constant contact of woollen trousers with the skin is accordingly not only objectionable on the score of cleanliness, but is liable to irritate and fret the skin of the thighs and "fork." The water-bottle consists of wood, with a very small opening to drink from. It is suspended by a shoulder strap placed over or under that of the man's equipment, according to regimental taste. It is very questionable whether this arrangement is equal to the former one, by which each soldier had a leather-covered water-bottle, loosely slung so as to be readily got at. The absence of a drinking cup, moreover, threatens to be a source of inconvenience on the march. We note also that the use of the old and convenient havresack seems to have been abandoned, at any rate, in some if not all the regiments, and are inclined to think that the innovation is by no means an improvement. Finally, we would observe that the present manner of slinging the shovels carried by pioneers seems capable of improvement. The belt passes directly upon the front of the soldier's chest, and the tool itself being suspended with the iron part downwards and over the hip, seems to interfere with the free movement of the carrier. Would it not be an improvement to reverse the present arrangement and have it secured with the iron upwards, the cross belt joined by a moveable button to that of the waist, so as to take off some of the direct strain?

PARLIAMENTARY CANDIDATURE OF DR. EVORY KENNEDY.

WE have authority for the statement that Dr. Evory Kennedy, of Dublin, intends to present himself as a candidate for the representation of Londonderry, which will shortly become vacant by the elevation of Mr. Dowse, the Irish Attorney-General, to the Barony of the Exchequer, which was occupied by Baron Hughes.

Dr. Evory Kennedy is a man who, as Master of the Rotundo Hospital, President of the College of Physicians, and an Honorary M.D. of the University of Dublin, has left a deep impression upon the history of the Profession, a mark which he has renewed by the bold challenge to the big Hospital system, which, by his papers on the "Genesis of Puerperal Fever," he lately put forth.

Dr. Kennedy is a Liberal in politics, and is understood in the Profession to be favourably regarded by the present Government, and, in undertaking so fierce a contest as that for Derry has proved itself to be, he braves a severe ordeal test of the sincerity and ardour of his political convictions. These are unhappily not times when a candidate for a seat in the House of Commons need be either a gentleman, or a man of truth, honour, or fortune, but with the better classes in such a constituency as Derry such attributes cannot, as against the claims of politico-attorneys or place-trafficking lawyers, be without their effect, and as Dr. Evory Kennedy can offer such qualifications to the electors we must hope—if only for

the sake of public propriety—that voters will not forget the difference between an educated gentleman of high social rank and Mr. John Rea, whose usual exit from the society of gentlemen is a forcible ejection by the hands of the police.

Having no politics, we have no choice of candidates on that ground, but we earnestly impress upon the Profession the consideration that nothing but a conscientious conviction that great and weighty public decisions are at stake ought to induce them to withhold their vote from their Profession. Every week illustrates the lamentable non-representation of Medical interest in Parliament, and, though we will not say that a Medical man is bound under all circumstances to give professional interests, a preeminence over political or religious ones, we imagine that there will be no anticipations of vital issues in the coming session such as to justify a departure from the principle of supporting an increased representation of Medicine.

ETHER AS AN ANÆSTHETIC IN OPHTHALMIC CASES.

THE superiority of Ether as an anæsthetic in ophthalmic operations which has been forcibly brought under the notice of the Ophthalmological Congress by Dr. Joy Jeffries, has been not anticipated but subjected to contemporary investigation and experiment in Dublin, and with a result quite as satisfactory and encouraging as that reported by Dr. Jeffries. Dr. Morgan, Professor of Practical Anatomy in the College of Surgeons has, by his communications on the subject in the *MEDICAL PRESS AND CIRCULAR*, put the Profession in possession of his views, and the facts almost at the same moment as Dr. Joy Jeffries. He has administered Ether with a new inhaler of his own design which he is now perfecting, in many cases in which ophthalmic operations have been performed by Dr. Jacob in the Dublin Eye and Ear Infirmary. Since Dr. Morgan's apparatus has attained completion, the method and result of administration of the Ether seem in the ophthalmic cases to leave nothing to be desired. In several cases of flap extraction of cataract it has proved to be entirely unobjectionable. It produces a quiet and rapid anæsthesia without any excitement stage whatever, the recovery is rapid, the circulation steady and unimpaired, and when the precaution of keeping the stomach empty is observed, attended with no sickness. It is for Dr. Morgan to prove, which, in the light of vast American experience seems not difficult, that Ether is to all intents, free from danger to life. If it is found to be so it will give to the operator a confidence and ease which is invaluable in the rapid manipulations of Ophthalmic Surgery, and which we venture to say is not to be had in the use of chloroform. The cases which Dr. Jacob has operated on under the influence of Ether have suffered nothing from disorder of stomach, and the recoveries have been in all respects, as satisfactory as those with or without chloroform.

TOLERANCE OF TRADE FRAUDS IN THE DRUG TRADE.

THE *Pharmaceutical Journal* in its last issue contends against the view of adulteration legislation which we have adopted, and to which we gave expression last week. That view, our readers know is, that a trader who, in the words of the original Bill, sells "as pure an article which is impure" is, according to every code of honesty, a rogue and ought to be dealt with as such. The Council of the Pharmaceutical Society considers that the vendor ought not to be called upon to know whether an article is pure or not, and has caused the Bill to be modified so

that a vendor shall not be punishable unless he "fraudulently" sells adulterated goods. This theory is simply a concession to the existing practice of adulteration, and would not be held to apply to any other form of commerce. If a ship builder contracted with an iron merchant to supply him with boiler plates of a specified strength and material, would it be for a moment permitted that the iron factor should send inferior goods and plead that the person from whom he got them was the rogue and that he was not obliged to know whether they were good or bad. Of course he would be speedily sued for breach of contract, and would retort, if he had really bought a better class of goods, upon the person who sold them to him. Why not enact in "matters of adulteration—a like rule in like case"? The Bill as it stood did not prohibit a person from selling a mixed article. It left it open to him to deal in any sort of matter which was not detrimental to health, but restricted him from selling them "as pure" when they were adulterated. Surely such a restriction is no hardship on any honest man, least of all on the dealer in drugs who is in a position to satisfy himself of the purity of his goods. Let him sell what he likes, but he should certainly be held responsible to sell nothing "as pure" which is not warranted as such, and if he then suffers for the roguery of the person who sells to him, he is afforded by the law an easy and satisfactory remedy.

As the Council of the Pharmaceutical Society have modified the Bill no penalty can possibly be enforced against the seller of adulterated goods, because it is totally impossible to prove that he knew them to be adulterated, and that, possessing such knowledge, he sold them "as pure."

Once more the shopkeeping interest has defeated a reform of the existing commercial immorality which is from day to day insuring merchants, middlemen, and retailers to a lenient and profitable tolerance of trade roguery. How can it be called dishonourable to make a fortune by wooden nutmegs, when the Government and the Council of the Pharmaceutical Society tell the dealers in them that they may "go ahead" so long as they take care not to enquire whether their wares are sticks or spices.

Notes on Current Topics.

Mr. Ayrton's Insolence.

IT is a great pity that we have no speedy mode of kicking out of office a man whose temper and conduct utterly incapacitate him from behaving in the manner that is expected of all gentlemen in public life. If Mr. Gladstone had followed up his statement that Dr. Hooker deserved well of his country by calling for Mr. Ayrton's resignation, not only the world of science and art, but all who have any regard for the ordinary courtesies of life would have felt relieved; for it is positively sad to feel that something is always brooding over us, and that at any moment one of H.M. Ministers may wreak his wrath on a subordinate by applying the most odious system of torture—that inflicted with no apparent object but the delight of gloating over suffering. That Mr. Ayrton's conduct calls for dismissal is everywhere felt. We only wonder that the House of Commons has tolerated his insolence so long, especially as the Liberals are quite as annoyed as the Conservatives with his conduct. Let us hear what first-class liberal journals write about him.

The *Spectator* says:—"Personally, Dr. Hooker is the superior, but officially he is the subordinate, of the First

Commissioner. Mr. Ayrton, therefore, being called on by Mr. Fawcett and Sir J. Lubbock for a reply to the general charge of unjust treatment of the Director of Kew, exerted his whole capacity—and the whole power of the man was never more conclusively shown than in this speech; it is forty times as able as his written memorandum—in developing this thesis, that when, as Justice Maule said, 'God Almighty was addressing a black beetle,' He could not be expected to choose his words. The whole drift of his reply was that he had not injured Dr. Hooker, and that Dr. Hooker was far too low an official to have a right to raise questions of manners with a Minister of the Crown. He was a mere subordinate spending £12,000 a-year, while the 'departments I control spend £1,200,000.' His were 'errors used by a slave to escape from the anger of his master, but which a master, conscious of his power, was not in the habit of using against a slave.' Is it necessary to analyse the speech further? or can there be a shadow of a doubt that a subordinate Minister who can use to a man like Dr. Hooker language a king would not use to a footman, or a judge to a convict at his bar, is incapacitated, by arrogance rising to a moral offence, for the service of the Crown?"

The *Examiner* considers that "Mr. Ayrton was more signally defeated on Thursday than he could have been by an actual vote of the House of Commons. He has been convicted of all the offences that were charged against him. He has been stung by the caustic humour of Mr. Bernal Osborne and has been trampled upon by the bucolic heel of Mr. Bromley-Davenport. We cannot hope that his punishment will cure him of the vice that is inherent and thoroughly hardened in him; but it will give him something to think over during these holiday months. He is not likely again to sin so openly as he has done in Dr. Hooker's case against good breeding, and we shall be surprised if he again calls down on himself such a torrent of abuse as he has thereby provoked."

Early Blistering in Pneumonia and Pleurisy.

S. S. HERRICK, M.D. (*Rich. and Louis. Med. Journ.*), has prepared a table of twenty-four cases of pneumonia and pleuro-pneumonia, with only three deaths, in which early blistering was resorted to. The beneficial effects were attributed chiefly to the promotion of absorption of effused products through osmosis, by increasing the flow of blood on the stimulated surface and in the adjacent tissues.

Mad or Not.

THE frontiers of sanity and insanity are not so clearly defined that they can be traced by every eye, says the *Globe*, adding that there are places where the division is so slight as to be imperceptible; and then arbitrators and counsel have to be summoned to decide the relative claims to the disputed territory. It is clear, continues our contemporary, that the board of arbitrators in such a case should be composed of men not only honestly desirous of forming a just judgment, but fully competent to the discharge of so delicate a task. The *Globe* then pursues its argument as follows:—

"It will, we think, be admitted by all who are following the correspondence in our columns on the subject of 'Sane and Insane' that the proper tribunal for determining a question of the sort is at least not that composed of two Medical practitioners chosen at random, and by parties interested in the suit. Yet such is the board which in this country usually decides whether a man is mad or a great wit—whether a man is to enjoy his liberty or end his life a prisoner."

This is *apropos* of a correspondence that has sprung up in the *Globe*, and which would perhaps be more influential if the letter writers had subscribed their names. We judge from these letters that some of the writers are both ignorant and prejudiced, and are sorry for our contemporary to give publicity to such a sentiment as this,—

"Within 'seven days of the patient's reception' the poor creature may, by virtue of the very steps taken after his admission, be reduced to that state which the Commissioners on the occasion of their visit would pronounce insane. Moreover, the report is a mere form which attracts no attention, and the 'case' is not seen by the Commissioners even in their purely perfunctory fashion until, perhaps, months have elapsed."

We have in our time seen a good deal of lunacy, both within asylums and outside them, and we do not believe in the stories that are so skillfully displayed by anonymous correspondents. Our reasons for scepticism need not be stated, as Medical men will readily recall them. Again, although we admit a great deal—perhaps too readily—about the want of information of some men who creep into the Profession, we were scarcely prepared for the following:—

"There appears to us to be no reasonable argument in favour of allowing any two ignorant men to determine cases of insanity because, after less than a half education, they may have dissipated about London for two years, and then obtained a diploma in Lincoln's Inn to practise upon all who choose to employ them."

That is hardly a fair description of even those men who content themselves with a single diploma, inasmuch as four years instead of two are required; and if the public will not take that interest in the Profession that is necessary to regulate the admission of men to practice, it is their own fault if a few half educated men should creep in. Will our contemporary aid us by urging on the public the need of a good Medical Reform Bill?

An Unguent for Multiple Bubo.

R. C. BRANDEIS, M.D., Vienna Correspondent of the *Rich. and Louis. Med. Journ.*, writes that Prof. Zeissl, Chief Physician Second Division for Syphilitics in the Vienna General Hospital, has achieved much success in the treatment of acute and subacute inguinal and femoral buboes by the application of a solution of acetate of lead to the glands; and in the case of a multiple bubo the following ointment of iodide of lead will afford speedier relief than the sugar of lead compress: R. Plumbi iodati, ʒj.; Ext. belladonnæ, ℞ij.; Emplast. diachyli, ʒj.; Unguent. elemi, q. s. to make a soft plaster. S. ointment.

The late Sir Andrew Smith, K.C.B.

THIS gentleman whose death is announced was Director-General of the Army Medical Department from 1851 to 1858. He served with distinction for short periods in various parts of the world, and proceeded to the Cape in 1821, returning to England in 1838. Shortly after he was sent to Fort Pitt, Chatham, and appointed Principal Medical Officer there. He was transferred to London by Sir James M'Gregor as his professional assistant, and on the retirement of Sir James in 1851 he was appointed by the Duke of Wellington to the vacant post, which he filled till 1858, when he retired from the service in consequence of impaired health, and received the distinction of K.C.B. Sir Andrew Smith's scientific researches in Southern

Africa resulted in the publication of many papers, and his great work "Illustrations of the Zoology of South Africa." It was upon his representation and advice that the prosperous district of Natal was constituted a colony. Sir Andrew Smith was born in Roxburghshire in 1797.

Muriate of Ammonia in Bronchitis, Catarrhal Pneumonia, etc.

In obstinate acute bronchitis, after the first intense stage; in catarrhal pneumonia, both of children and adults; in bronchorrhœa, and also in ordinary chronic bronchitis, Dr. H. C. Wood, Jr., Phila. (*New Remedies*, April, 1872), has obtained more apparent good from the use of muriate of ammonia than any other remedy. The best formula for giving the muriate with which he is acquainted is as follows:—R Ammoniae muriat. ʒij.; Ext. glycyrrhiz., ʒj.; Mucil. acaciæ, Aquæ, āā f ʒijj. M. S. Teaspoonful for an adult every two hours; teaspoonful for a child, a year old, every three hours.

When patients object to the mixture of sweet and salt the following is to be preferred: R Ammoniae muriat. ʒij.; Aquæ, f ʒvj. Dose as before.

When the cough is very annoying 1-20th of a grain of sulphate of morphia, or 10 or 15 minims of tincture of hyoscyamus, may be added to each dose.

In bronchorrhœa the following may at the same time be used by inhalation twice or thrice daily. Take of Sat. solution of alum, ʒvj.; Tr. hyoscyamus, ʒss. M.

Cholera in India.

This plague (says the *Bombay Gazette*) is raging furiously at present in the Punjab. No fewer than 32 cases of cholera occurred in Umballa during the previous three or four days, the greater portion of which proved fatal. The disease was then evidently subsiding, as there were only two fresh cases. There have also been a large number of cases at Agra, where the epidemic broke out on the 5th inst. in St. Peter's College. On that day 21 of the boys in the college were attacked, and altogether in five days there were 82 cases, of which 85 proved fatal. There were besides, some cases in the neighbourhood of the city.

We read in the *Madras Athenæum*: "The dengue fever is spreading amongst us, though no cases of a severe type have yet presented themselves. We are probably better prepared for it than were the people of Calcutta when it first attacked that city, and we need not at present, judging from the slow progress the disease has as yet made amongst us, relinquish the hope that we may get through the visitation without the occurrence of any serious or aggravated cases."

Cerebro-Spinal Meningitis.

DR. N. S. DAVIS, of the *Chicago Medical Examiner*, uses with success in this disease the calabar bean, either alone or in combination with ergot. He believes that such remedial agents as have the power to diminish excitability, and at the same time increase the vascular tonicity, exert the most favourable influence over the active stages of its progress. Such are the calabar bean, cannabis indica, gelseminum, ergot, &c. In the active stage of the disease he has not found either opiates or quinine to produce any favourable effects.

The Whitworth Science Scholarships.

Two of the scholarships founded by Sir Joseph Whitworth, value £100 a year for three years, have just been awarded to Mr. Robert Coey and Mr. George W. Sutcliffe, students in the Royal College of Science at Dublin. The competition for these scholarships is very severe. They are open to competitors from all parts of the United Kingdom, only ten of them being filled annually. Messrs. Coey and Sutcliffe are distinguished students of the Royal College of Science, having obtained, on competitive examination, two of the Royal Exhibitions attached to the college, and carried off many of the highest honours of the last session. It is not long since a similarly successful career was achieved by another student of the College, Mr. T. W. Phillips, who also obtained a Royal Exhibition, and subsequently a Whitworth Scholarship.

Treatment of Diphtheritic Croup.

In a paper on "Diphtheritic Croup and its Treatment," read before the Buffalo Medical Association, by F. W. Bartlett, M.D. (*Buffalo Med. and Surg. Journ.*), several cases of diphtheritic croup are detailed, in which a small blister over the nucha, and common salt dried and powdered, blown by the aid of a tin tube into the fauces, were of great service to the patients in relieving the croupal distress. We are told that it is important not to heal the blister by any application but rather to let it heal in its own way. If a blister is to be applied it should be at the earliest possible stage of the malady, so as to arrest if practicable the initiatory morbid changes in the mucous membrane of the larynx and the trachea. In later stages of the disease it is far less likely to succeed, and if successful, the respiration and voice particularly are much more slowly restored.

The late Mr. Skey, F.R.S.

THE death is announced of Mr. Skey, the venerable ex-surgeon of St. Bartholomew's, whose lively letters on athletics and remarks on alcohol showed how at an advanced age he preserved much of the energy of youth. He died last Thursday at the age of 73. He was a pupil of Abernethy. He obtained his F.R.S. for his paper "On Muscular Fibre," but was better known to the Profession as a skilful surgeon of great experience.

It will be remembered that Mr. Skey was chairman of the Commission for Enquiring into the Venereal Diseases that preceded the recent acts. He was for a long time not only a member of the Council and an Examiner of the College of Surgeons of London but had filled the office of President. Perhaps his work "On Operative Surgery" was his best, but he was the author of other well-known volumes.

Ovarian Cyst in a Child Eight Years Old.

DR. C. G. GOODRICH (*Northwestern Medical and Surgical Journal*), reports a case of ovarian cyst in a child eight years of age. The child was tapped three times. His attention was called to the case during convalescence from typhoid fever; the tympanitic distention of her abdomen did not disappear as in others of the family who had also been ill with fever. The autopsy revealed an ovarian cyst, with extensive adhesions to the peritonæum and liver.

Cholera Remedy.

New Remedies for April, 1872, contains the following cholera prescription, a favourite one of Dr. H. Hartshorne, of Philadelphia: R Chloroform, Tinct. opium, Spts. camphor, Spts. ammonia aromatic, aa f ʒ iss.; Creosote, gtt. iij.; Oil of cinnamon, gtt. viij.; Brandy, f ʒij. Mix. Dilute a teaspoonful with a wine glass of water, and give two teaspoonfuls every five minutes, followed by a lump of ice.

It is announced by the *Chemist and Druggist* that Mr. Holloway, the proprietor of the pills and ointment was about to endow some charitable institution in a most magnificent manner. To build a hospital might, perhaps, indicate a declining faith in those wonderful remedies which have so often succeeded when all other remedies have failed. It is therefore said to be Mr. Holloway's design to erect, at his own expense, a middle-class asylum at Virginia Water. The asylum will cost from £70,000 to £100,000, and will accommodate 200 patients. It will be maintained for a year by Mr. Holloway, after which it is expected to be self-supporting, and will be handed over to the management of trustees.

Foreign Medical Literature.

CONTRIBUTION ON THE THEORY OF ILIO-TYPHUS.

From the Clinique of Professors SKODA and OPPOLSOR.

Editorially reported in the *Allgemeine Wiener Medizinische Zeitung*.

(Translated for the MEDICAL PRESS AND CIRCULAR by THOMAS BODKIN, F.R.C.S.I., &c., &c.)

In addition to the many and masterly expositions by these celebrated authors which have already appeared at various times during several years in our journal, we deem it desirable to reproduce them in a fuller, more complete and corrected form than that they have hitherto appeared in, we do so for the special interest of our readers which they have a right to demand, in reproducing these views already expressed by Skoda and Oppolsor, we wish to treat of them more fully, not in connected additions of our own, or in diffusely detailed statements, but only on peculiar occasions and special cases, to give in valid conciseness their expressed conceptions, compatibly condensing their dispersed and outlying observations, in thus carrying out our expressed views we will hope to obtain the favourable opinion of our esteemed readers.

When the contagion, or according to some authors, the miasma and which in some undecided way, enters into the organism, after a shorter or longer incubation, a slight indisposition is complained of, an increased temperature and feverishness as the first indication of the seizures, yet it is not always that the febrile manifestation by which the typhus sickening is characterised, for these signs are very frequently entirely absent; the disease may advance in its incipency in the absence of any appreciable local disturbance, developing itself in very many and different ways, so that in fact there is no organ in the body from which typhus may not manifest its origin, nevertheless, febrile symptoms may co-exist with the local affections, cerebral disturbance comes on above all in frequency on the advent of ilio-typhus, these symptoms may be very early present, yet the patient finds himself still out of bed, has some amount of appetite, feels neither chilled or heated, but finds his head already out of order, his mind perplexed,

and his sleep disturbed. Otherwise it proceeds with maniacal or epileptic attacks, or it may exhibit a decided and strange melancholy, or it may set in with the symptoms of a meningitis, encephalitis, endocarditis, gastritis, jaundice, albuminuria, the intermittent, a bronchial catarrh, an angina, an infiltration of the lungs, or articular rheumatism.

It therefore appears sufficiently evident that the incipient manifestation of the typhus process is variable in a high degree, so that, consequently, in the primary progress of this disease nothing can be laid hold on to ground a decided and unequivocal diagnosis, and hence the great liability of being deceived by erroneous conceptions, in a particular case a totally different disease may be assumed than ilio-typhus; during the further progress of the symptoms, as the illness progresses a more and more marked unfolding of the special nature of the disease is given.

These variable phenomena of ilio-typhus on its first apparition have led to a series of painstaking inquiries to discover the distinguishing characteristic symptoms of its first stage, we must, however, alas, confess that efforts in that direction up to the present day remain almost entirely fruitless.

The numerous and very difficult obstacles manifested in the first stage of ilio-typhus opposed to the diagnosis, remaining as yet unsolved, urges the necessity of future and closer observations of more numerous cases, observing in what ilio-typhus may be simulated, conscious as we are that the acknowledged obstacles have not been sufficiently investigated, so that for the future more extended and fuller data should be collected and the earlier development of the difficult complications be especially observed, and thus hopes may be entertained that with the aid of existing precepts and records, the help of science as far as it goes up to the present, that with this powerful assistance the settling and securing of the diagnosis may be accomplished.

It happens not so very seldom that ilio-typhus commences with the absence of fever, but sets in with disturbance of the cerebral functions, and the typhus in such a case may simulate mental disease; the patient naturally intelligent, becomes quite confused, loses his memory, suddenly talks incoherently, becomes deranged, ultimately maniacal, or gets convulsed, whereas, up to this, nothing remarkable of any such tendency could be noticed; on the other hand, the appetite is still extant, the food is not objected to so that it is possible a mistake is liable to be made in such a case in diagnosing it as a disease of the mind, such cases are not so very rare, their course is tedious, and, according to Skoda, the number of such cases having occurred are not with sufficient accuracy ascertained; however, it may be remarked that scarcely a year passes during which such cases may not be observed in the clinical wards of our public hospitals, which are recognised by those about and by the doctors as cases of insanity. Now, when ilio-typhus as mental derangement, as mania, or as melancholia sets in without fever, so it is almost impossible at the commencement in such a case to fix the diagnosis, and ilio-typhus will, in the progress of its development, be known to be such, when fever and diarrhoea set in, when the spleen swells and meteorism appears, then comes the *eclaircissement*, yet still very doubtful.

But in such extreme cases there is a saving point not to be overlooked, which may at least lead to the suspicion that in such like cases ilio-typhus may lie concealed under such appearances when possibly a morbid tendency to mental disease is not apparent, the affected person up to the present has been perfectly sound, rational, and, according to his individual disposition, clear-minded, cheerful, or serious, correct in all his habitual transactions, and anything abnormal never having been manifest in the cerebral functions; the physician generally in such a case by close observation and careful induction will infer, more particularly if the patient is young, that he is not a special case of mental disease, but far more pro-

bably one in the advanced stage of ilio-typhus that he has to treat, should the mental alienation develop itself in the more advanced stage, the diagnosis already determined on will remain unaltered.

Furthermore, ilio-typhus, as most generally occurs, commences with the usual indications, such as fever and general prostration, and when after the fever has advanced a few days, brain disturbance is frequently manifested by very decided delirium, followed afterwards with somnolency and stupor, the brain is with many individuals in the commencement of typhus sickening, the seat of disturbance, and so it may be that the active delirium may be the earliest recognised symptoms; coinciding with the commencing febrile movement may be hyperæmia of the brain, whilst the delirium in the later stages is not the result of hyperæmia, but the alteration in the entire nervous system; under the appearance of these early and severe symptoms, lie grounds for suspecting the near approach of meningitis or encephalitis; therefore, there exists in this category many connected points of differential value, it is for instance, of primary importance that in the implications of the brain or its membranes, not alone disturbance in the mental process, but in the order of the disturbances, in the power of perception, in the integrity of the power of vision, and in the mind should be well noticed. In meningitis there are symptoms of disturbance of the cerebral functions, sometimes characterised by excitement, sometimes by depression, or with complete paralysis, in the acute stage severe pain of head occurs of which the patient shows his consciousness when his head is disturbed; meningitis is accompanied by very increased sensibility to noise, intolerance of light, grinding of the teeth, convulsions, further on comes strabismus, diplopia, and a peculiar rolling of the eyeballs before inequality of the pupils occur, they are sometimes dilated, sometimes contracted; true it is that one observes among some cases a remarkable difference in the pupils in many instances, in the commencement the pupils are contracted, whilst towards the end when the latter stage approaches a dilatation and insensibility of the pupils occur, yet these appearances may still be altogether absent.

(To be continued.)

Medical News.

The Military Secretary, India Office, presents his compliments to the Editor of the MEDICAL PRESS AND CIRCULAR, and begs to enclose a list of the Candidates for Her Majesty's Indian Medical Service, who were successful at the competitive examination at Burlington House, February, 1872, and who have undergone a course of instruction at the Army Medical School, together with the total number of marks obtained at the examinations in London and at Netley.

Apothecaries' Hall of Ireland.—At a meeting of the General Council of the Apothecaries' Hall of Ireland, held in pursuance of the Statute of Incorporation, on the 1st inst., the following gentlemen were elected office-bearers for the ensuing year:—Governor—Thomas Collins. Deputy-Governor—Edward J. O'Neill. Court of Directors and Examiners—Edward Howard Bolland, Charles Holmes, Arthur Harvey, Charles H. Leet, Robert Montgomery, Charles F. Moore, Henry P. Nolan, Jerome O'Flaherty, George B. Owens, John Ryan, James Shaw, John Shea, George Wyse. Examiners in Arts—John Wm. Moore, Edward Collins. Representative on the General Medical Council—C. H. Leet.

Dislocation of Humerus into Axilla.

DR. E. P. BENNETT, of Danbury, Conn. (*Med. Record*), recommends the following plan, and claims it as original with himself: "I place the patient upon a common chair. I pass around the body, below the arms, a broad strong towel, the ends of which I give to a stout assistant. The next step, and the most important of all, is to firmly fix the scapula. Without this precaution you will be pretty sure to fail, pull as hard and as long as you please. To fix the scapula, I direct one intelligent assistant to place the ball of the hand firmly against the acromion process; then tie a handkerchief around the arm directly above the condyles, and make it into a loop for my right hand, then, with the arm hanging down closely to the body, I pull gently and steadily directly downwards, and, with my left hand on the axilla, the bone slips easily and quickly into place. Now in this dislocation the head of the bone lies under and in contact with the neck of the scapula, and if by any means you can depress the head of the bone to the extent of one-eighth of an inch, or even less, there is nothing to prevent your gliding the bone easily into place, and that, too, without injuring any of the joint structures."

NOTICES TO CORRESPONDENTS.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this request.

All communications intended for insertion, must bear the name and address of the writer; not necessarily for publication, but as a voucher of good faith.

Rejected MS. will always be returned, if a request be received from the author, within one week after the article or letter has been declined.

SUBSCRIPTIONS IN THE UNITED STATES.—A Correspondent has drawn our attention to the fact, that some of the houses in the United States are charging the enormous figure of 15 dollars per annum (more than £3) for supplying this Journal to different parts of the States. We beg, therefore, to state that we shall be happy to supply the same regularly post free per annum, if paid in advance, for considerably less than half this amount, viz., six and-a-half dollars (about £1 6s. 0d.), either direct from our offices in this country, or through our recognised agents in the United States.

To our SUBSCRIBERS.—It having been suggested to us that it would be a matter of great convenience to Subscribers visiting the metropolis to know where they can give instructions for their letters to be addressed previous to leaving home, we have pleasure in informing them that the Publisher has consented to take charge of letters addressed to his care, and that he will place a desk at the disposal of Subscribers whose names are upon our lists, for short correspondence, where such accommodation is desired.

THE FOOD REPORTS.—The next Series of Chemical and Physiological articles upon the important subject of Food, will be devoted to Meat Extracts, Australian and other imported Preserved Meats. We trust this Series will be as useful to our readers in determining the relative value of food substances, and provoke as much interest generally as those which have already appeared. We shall be fully prepared to give the results of our investigations in the course of two or three weeks.

A CASE OF REAL DISTRESS.—Since the publication of our last we have received 2s. 6d. from D. Ennis, and 10s. from R. P., Brecon, which we thankfully acknowledge. We would also take this opportunity of assuring those kind friends who contributed, that happily there is now no further need of funds.

ASSISTANT-SURGEON MACROBIN'S translation from Dr. Carl Ficher's Notes is in type, and will appear in an early number.

MILITARY MEDICAL EXAMINATIONS OF CANDIDATES FOR HER MAJESTY'S SERVICE.

To the Editor of the "Medical Press and Circular."

SIR,—I should be much obliged for an answer to the following question:—

Short Sight.—What constitutes short sight in a military point of view? How, and in what manner, a candidate is examined on this subject, so as to say he is, or is not, fit for the service? I observe in the examinations for Woolwich, extreme short sight is an objection. I should like to know how extreme short sight is tested, or to what point of print reading short sight is admitted.

Almost all German officers of note, particularly engineers, appear to wear glasses for short sight. Perhaps talent for artillery or engineering go with short-sighted persons. An answer to my question from some competent authority will oblige, yours truly,
A. SUBSCRIBER.
August 14, 1872.

[Perhaps some of our readers may be able to give the information asked for by "a Subscriber." We have heard that the test for short sight was the capability of the candidate to read the *Times* at ordinary reading distance, and perhaps it is as good as any other. The use of glasses by German officers may be as characteristic of short sight and genius in them as spectacles, long hair divided down the middle, and turned-down collars are supposed to be of talent in this country.—Ed.]

VACANCIES.

Anderson's University, Glasgow. Chairs of Natural Philosophy and Medical Jurisprudence. Applications to be sent in before the 28th inst. Gloucester Lunatic Asylum. Junior Assistant Medical Officer. Salary £80, with board.

Dover Hospital. House Surgeon. Salary £80, with residence. Uttoxeter Union. District Medical Officer. Salary £32 per annum. Burton Infirmary. House Surgeon. Salary £130. Huddersfield Infirmary. Assistant House Surgeon. Salary £40, with board.

Westminster Hospital. Resident Obstetric Assistant. Board, no salary.

Great Northern Hospital, London. House Surgeon, and a Junior Resident House Surgeon. Applications to be sent in before the 28th instant.

London Dispensary, Spitalfields. Physician. Honorary. Ladies' Medical College, London. Professorship in Midwifery. Stipend not less than £120. (See advt.) Sussex County Hospital. House Surgeon. Salary £80, with board. Liskeard Union, Cornwall. Medical Officer. Salary £85 per annum. Metropolitan Dispensary, Cripplegate. Physician. Honorary.

Clinical Medicine—Physicians to the Royal Infirmary.
Clinical and Practical Surgery—Surgeons to the Royal Infirmary.
The WINTER SESSION will open on the 1st October, and attendance will be given daily from 12 to 2, at the Medical School, 10 Faulkner Street, up to the 14th October, for Registration.
Three Scholarships of the value respectively of £20, £15, and £10 are open Annually to the competition of perpetual Students; and Prizes for general proficiency, and Certificates of Honour for regular attendance and good conduct are awarded at the end of each Session.
A Composition fee of 40 guineas admits to the whole of the Lectures, and a further Composition fee of 40 guineas to the Hospital Practice of the Royal Infirmary.

Prospectuses may be obtained from the Registrar at the College, or the Vice-Registrar at the School.

J. G. GREENWOOD, Principal.
J. HOLME NICHOLSON, Registrar.

THE OWENS COLLEGE, MANCHESTER.—The next SESSION commences on the 7th OCTOBER.

Candidates for Admission must not be under fourteen years of age, and those under fifteen will be required to pass a preliminary examination in English, Arithmetic, and the Elements of Latin.

Prospectuses of the several departments of the Day Classes, the Evening Classes, and the Medical School, and of the Scholarships and Entrance Exhibitions tenable at the College will be sent on application.

J. G. GREENWOOD, Principal.
J. HOLME NICHOLSON, Registrar.

DISTRICT LUNATIC ASYLUM, IRELAND.

THE OFFICE OF RESIDENT MEDICAL SUPERIN-

TENDENT of the District Lunatic Asylum at Waterford being now vacant, Candidates for that office are requested to forward their Testimonials, with a statement of their peculiar qualifications for the appointment, to the Under Secretary, Dublin Castle, on or before MONDAY, the 26th instant, in order that the same may be submitted to His Excellency the Lord Lieutenant.

Applicants must be duly qualified to practice, both in Medicine and Surgery, and registered as such under the Medical Act of 1858.

Candidates are requested to specify their age.
The Candidate who may be selected for the office in question, will have to enter upon his duties forthwith.

ETHER *versus* CHLOROFORM.

ON THE USE OF ETHER AS AN ANÆSTHETIC IN SURGICAL OPERATIONS; AS A SAFER AND MORE EFFECTIVE AGENT THAN CHLOROFORM IN PRODUCING THE AVOIDANCE OF PAIN.

With a Description of an Inhaler, and the Mode of Administration.

By J. MORGAN, M.D., F.R.C.S.,

Professor of Surgical and Descriptive Anatomy Royal College of Surgeons, Dublin, Surgeon to Mercer's Hospital, &c.

(Continued from page 147.)

It has been stated that Etherization is more tedious than Chloroform in its action. I find this by no means the case. When the time occupied in gradually bringing a patient under the influence of Chloroform, and in proportioning the amount of the Chloroform inhalation to the varying conditions of the pulse and system, are both taken into account, I do not think there will be found much, if any difference in time, when the aggregate of cases is taken; but even if an additional few minutes were consumed (which I do not admit) the *safety* of Etherization will amply counterbalance any inconvenience on that score.

It is to be remembered, that with regard to this question of time, there is a diversity of opinion, and as I have already mentioned, practitioners of eminence and experience (a) assert, that, "anæsthesia may be induced by means of Ether as quickly as can safely be done by means of Chloroform." Much evidently would depend on the mode of administration; the aid given by the patient; and the purity of the Ether. I have seen instances where these conditions were attended to, and where Etherization was

more rapidly induced, even in *half* the time which had been occupied in the administration of Chloroform on previous occasions, to the same patients.

The solution of the question of time, appears to be in a great measure dependent on the amount of Ether vapour which is taken by the patient. In the directions given for Etherization it is stated, that some use the sponge or the cone of paper, and it is remarked "that enough air gains admission through the interstices of the (b) sponge moistened with Ether held over the mouth and nose." While others arrange the apparatus so as to prevent "the slightest admixture of air" (a) as does Professor Porta, of Pavia, "who stops the nostrils and uses a bladder closely fitted to the mouth" (b).

Dr. Smith, of New York, uses a large india-rubber ball, with an aperture cut for the face. The ball is lined with lint, which receives the Ether.

Dr. Lente uses a cone of paper, with a towel pinned inside, and so folded as to prevent any, "even the slightest admixture of air."

While, therefore, we find it stated that "the admission of air is comparatively of little consequence," that "enough air enters through the interstices of the sponge," and, again; that it is endeavoured "to prevent any, even the slightest admixture of air," evidently there is abundant proof of the *safety* of ether, and of the efficiency of its action. Some of the objections which have been urged against its use, of causing delay, sickness of stomach, headache, or spasm, are dependent on this very diversity of application, as it is found by those surgeons who exclude air that the results are satisfactory in the extreme.

We have here the key of the question. Ether vapour being considerably heavier than air, when applied by the sponge would flow away unseen from the mouth and nose, and much of it thus escape inhalation, while from being concentrated, and more efficiently applied by the other modes last described, it would act more satisfactorily and produce anæsthesia "as quickly as can safely be done by means of Chloroform." (b)

(a) Dr. Lente, Dr. Squibb, Dr. Godon.

(a) Dr. Lente.
(b) Asshust, p. 77.

The mode chiefly in use for the administration of Ether has been that mentioned in the latest and in the majority of the works on Surgery from America (a); by using "a thin and hollow sponge, which is large enough to cover the mouth and nose, and which is first wrung out of warm water, and saturated with Ether poured on in quantities of not less than half a fluid ounce; this is laid on, and a cone of pasteboard or light wood superimposed. The first few inhalations should be made when the sponge is a little distance from the face; but as soon as the anæsthetic influence has begun, the sponge may be more closely applied, and need not be removed except when necessary to apply more ether. Of course if, as will sometimes happen, the patient be seized with a fit of coughing, or, from having eaten a meal immediately before the operation, he should begin to reject from the stomach, the sponge must be withdrawn until tranquility is restored. *If the patient breathe freely he cannot be too rapidly Etherized, and there is no danger as in the case of Chloroform from the vapour being too concentrated.* Enough air is drawn through the interstices of the sponge and the perforation of the cone to obviate any risk from this cause, and rapid Etherization is much less apt to cause pulmonary congestion than slow inhalation of the vapour, prolonged through considerable time."

Such are the general directions given by a surgeon who avows that he prefers Ether.

I select, in contrast, the directions of a surgeon (Dr. Gross), who prefers Chloroform. He observes as follows:—

ETHER.

During the process of Etherization the patient may sit up with impunity or be recumbent as may suit the convenience of the operator, no injury resulting from even a protracted maintenance of the erect position.

The admission of air is comparatively of little consequence.

The inhalation should be commenced with not less than half an ounce, and diligently maintained till full anæsthetic influence is produced, which usually requires a considerably longer period.

No special attention need be paid, as the fluid possesses none of the poisonous (!) properties of Chloroform.

EFFECT.

At first a short cough is usually provoked. This soon sub-

CHLOROFORM.

During the process of Chloroformization the patient must lie down, and not only so, but the head and shoulders should be depressed, owing to the greater difficulty of maintaining the circulation of the brain through the influence of the heart's action.

The importance of having an abundance of air during the inhalation of an article so potent as Chloroform is self-evident; it is absolutely essential to the safety of the patient.

The inhalation should be gradually, and not hurriedly, effected, time being allowed to allow the accommodation of the system to its influence, avoiding the shock which might otherwise result to the heart and brain. From six to eight minutes should be spent in producing its full effect.

The assistant having the charge of the process must give it his earnest and undivided care; and as soon as the inhalation has been fairly entered upon, one of the attendants should sedulously watch the state of the pulse, the respiration, and the countenance.

EFFECT.

This may be divided into two stages:—1st. That of ex-

sides, and the system gradually lapses into a calm, quiet condition, attended with muscular relaxation, closure of the eyelids, and mental unconsciousness followed in many cases by stertorous breathing.

citement, when the patient struggles and cries. The eye has a wild, staring expression, the face is flushed, and pulse preternaturally quick. This varies much in degree and duration. The second stage then ensues, and the individual gradually lapses into unconsciousness. Feeling and intellect are suspended, and if this state be carried further, coma will ensue, and the appearance be apoplectic. As yet all is safe; but a few more whiffs, and an important link in the chain of life may give way, and the patient be sent into eternity.

The writer lays considerable stress on the importance of using caution, and good Chloroform, and ascribes the good luck he has so far had in his practice (though he gives one instance of a narrow escape, where artificial respiration was necessary) to the careful observance of these conditions.

On contrasting the comparative merits of the two anæsthetics as described by him, "good luck" is not indeed an exaggerated term when applied to the use of an agent so fraught with danger, and when we find such a suggestive expression used by a writer of eminence, it cannot be questioned that Chloroform, with its signal dangers, has claims far inferior to Ether as a pain-destroyer, and that such a resolution as was adopted by the Massachusetts Hospital—"that the exclusive use of Ether should be an absolute law of the Institution" (a)—was most advantageous for the patients.

MODE OF ADMINISTRATION.

Having referred to the diversity of opinion as to admission and non-admission of air during the process of Etherization, I may state that I adhere to the general correctness of the latter view, and cannot adduce better evidence than the following practical illustration:—

I etherized a medical man, aged about 24, as intelligent and fine as Chloroform is self-evident; it is absolutely essential to the safety of the patient. The inhalation should be gradually, and not hurriedly, effected, time being allowed to allow the accommodation of the system to its influence, avoiding the shock which might otherwise result to the heart and brain. From six to eight minutes should be spent in producing its full effect. The assistant having the charge of the process must give it his earnest and undivided care; and as soon as the inhalation has been fairly entered upon, one of the attendants should sedulously watch the state of the pulse, the respiration, and the countenance.

In this muscular young man there was not the slightest spasm, or any unpleasant symptom; there was not the slightest irritability of stomach, and within one hour afterwards he enjoyed a capital dinner. His description from personal observation includes the general rules to be observed—of avoiding irritation at the very commencement, and of then pressing on the influence, to the exclusion of air in a great measure; when this is done there is little apprehension of spasm, or sickness, or of delay.

In conducting Etherization the following points should be attended to:—

The patient should not have eaten any meal within three to four hours. A glass of wine, or a cup of tea

(a) Neligan's "Medecines." By MacNamara.

NOTE.—August 9.—I operated on four patients to-day—one was etherized, had two tumours of the leg excised, and was in bed again within ten minutes; another was etherized and had a tumour removed in eight minutes; two others underwent the process in about from six to eight minutes—nothing could possibly have been more satisfactory.

(a) Ashurst.

may perhaps be allowed within two hours of the Etherization, unless in cases where stimulants are urgently necessary. If this simple rule be attended to, the instances will be indeed very exceptional, in which sickness of stomach will occur. In eye operations, it is needless to remark, exact precautions should be taken.

The patient must be freed from any tight clothing, and from stays or strings which might in any way impede full respiration. The recumbent position is best suited, with the head fairly raised on a pillow; lying on the *side* I find better than on the back, but it is a matter of no very great importance; patients can also be etherized equally well when sitting, but the relaxation of the muscles supporting the head and body leads to inconveniences, and the recumbent position is certainly preferable in all cases.

The inhaler is then charged with from $1\frac{1}{2}$ to 2 ozs. of pure anhydrous sulphuric ether (*a*), which should be poured in slowly. The mouth-piece is then applied gently over the mouth and nose. The patient may hold it and keep it applied for the first few minutes; this lessens any nervousness about its use, and the mouthpiece can be taken away at pleasure so as to moderate the inhalation and accustom the throat to the vapour. The patient should be directed to cough or blow out, and as each such action is followed by a full inspiration; such effort aids the breathing in of the vapour very materially, and I am convinced the more freely and fully the Etherization is pressed till insensibility is attained, the better for the patient. After two or three minutes any irritation will be passed, and the breathing will be carried on regularly. The mouth-piece may be then taken charge of by the administrator, and the patient's hands laid down, the breathing will gradually become full, and the stage of insensibility steadily and equably ensue. This may be pushed, even till stertorous breathing ensues, which need cause no alarm, but as perfect insensibility is attained without it, it is not necessary further to overwhelm the patient.

The administrator will now suit himself to the circumstances of the case: the patient's condition is altogether in his hands, should there be signs of the ethereal influence passing off, he can pour in a little more, and should the contrary appearances arise, he can, by opening the funnel, allow air to be more or less freely admitted into the inhaler, or he can withdraw the mouthpiece temporarily.

The mouthpiece being usually made of elastic tubing should be pressed firmly on the face, or be slightly moulded to the nose if required, it is well after the few first inhalations, to apply it equably and closely, thus Etherization will be attained more rapidly and satisfactorily.

It is best to preserve silence, and not encourage the patient to speak.

If attention be directed to the flexible diaphragm of the inhaler, its motion serves as an index, and an estimate can be always formed as to the condition of the respiration, and how far the patient from timidity or otherwise, is not fully respiring, or the administrator is imperfectly applying the mouthpiece and allowing the escape of the vapour.

Should it so happen that the stomach be sick, and any food have been recently taken, the head should be turned on the side, and the chin slightly depressed, to favour the expulsion of the food.

The ascertained ratio of only one accident been known to occur in 23,204 cases of Ether inhalations, puts the probability of any complication beyond notice.

The operation over, the patient may be allowed to recover gradually, and if the face be sponged with cold water, and the patient soothed when emerging from the influence it will be best.

The time occupied in producing insensibility by the Inhaler varies a little, and some patients seem to resist somewhat more than others. I have seen very many thoroughly insensible in four minutes—others in five; but if eight minutes be taken as an average, it will be found that few cases indeed will exceed it, while the vast majority will fall short of it. *I refer to cases where the Inhaler is used*, as I have comparatively tested the cone and sponge with it, and find that not only is the time much longer, but the effects are far less satisfactory, both as to the temporary and after condition of the patient with the cone and sponge; or, in other words, where a free exposure to the vapour is not effected.

I must here remark that the convulsive stage produced by Chloroform inhalation is not seen where Etherisation is used by the Inhaler, save in *very* rare instances; nor is sickness of stomach usual, if the simple precaution be taken of not allowing any meal to be given within a few hours of the operation. Indeed, the result of Etherisation cannot be better expressed than by the quotation I have given above from a writer who advocates chloroform:—

"The system gradually lapses into a calm, quiet condition, attended with muscular relaxation, closure of the eyelids, and mental unconsciousness."

When, in addition to these perfect results, it is remembered that it is proved by the hard logic of statistics that *Ether is the safest of all anaesthetics, and eight times more so than Chloroform*, I can hardly conceive that anything further is required to prove its superiority to all other agents.

THE ETHER INHALER.

is constructed so as to collect the Ether vapour rapidly, and have it inhaled through the flexible tubing, which, with the mouth-piece, suits any position of the patient.

The respiration is allowed to be carried on freely by means of an india-rubber diaphragm at the top of the instrument, which, by corresponding with each respiration, is self-accommodating. The internal arrangement is such that ample provision is made for the collection of the Ether vapour.

When about being used, pour in *gradually* two fluid ounces of anhydrous sulphuric ether, if for an adult, but proportionably less for a child or female, and apply the mouthpiece to include the mouth and nose. Should the patient not yield in four or five minutes, pour in another two ounces gradually—more will seldom be required, except during some very prolonged operative procedure. It is desirable to keep the inhaler in the erect position as much as possible.

I am persuaded that any practitioner who employs Ether in the manner I have described will be completely satisfied with the results.

He will also be freed from the incubus of the

DANGERS OF CHLOROFORM.

He can conscientiously advocate with his patient the employment of an agent which has been proved to be, though hitherto used in an imperfect manner, the

SAFEST OF ALL ANÆSTHETICS.

He will avoid responsibility and the qualms of conscience which, in case of a fatal issue from using the more dangerous remedy, Chloroform, must result to him, indicated in the truthful and touching remark of a practical surgeon when relating the fatal effects and dangers of Chloroform which he himself witnessed:—

"The use of Chloroform is a serious business, involving as it does the issues of life and death—how serious few can realise, except those who have seen one or more fatal cases;" and "witness that sad sight when a person lies dead before them, who but a few minutes before was in full possession of life and strength (*a*)."

(a) That prepared from methylated spirit, of 720 Sp. g., answers well.

Special Report

ON

DISEASES OF THE THROAT.

Edited for the "MEDICAL PRESS AND CIRCULAR."

By PROSSER JAMES, M.D., M.R.C.P.,

Physician to the Hospital for Diseases of the Throat and to the North London Consumption Hospital; Lecturer on Materia Medica and Therapeutics at the London Hospital.

II.

The Practice of Laryngoscopy. Position of Patient and Physician. Warming and Introduction of the Mirror. Control of the Tongue—by Tongue Depressors, by holding. Cautions and Directions.

INSTEAD of a lens a glass globe, filled with water, may be placed before the lamp. Türk appears to have been the first to try this mode of illumination, which is still constantly used by Störck, one of the most able teachers of laryngoscopy. As a support, Türk used a single rod, so bent as to cause the centre of gravity of the globe to fall about the middle of the heavy foot. Störck suspends others.

Dr. T. J. Walker, of Peterborough, improved this apparatus by suspending the globe from a cross-bar, which is supported by two upright metal rods. Moreover, he added to it a small plane mirror, thus enabling the operator to examine his own larynx, and at the same time show it to the globe from the top of the frame by a screw, which enables him easily to alter its height.

FIG. 9.

These instruments are all more or less adapted for demonstration. Dr. Smyly, of Dublin, has devised for this purpose a very simple and ingenious method. He uses a perforated reflector supported by a forehead-band, to which is fixed a square plane mirror. The reflector is fixed as usual before either eye, and the square mirror into which the pupil looks, covers the other, as is very well seen in the above engraving.

To obtain a view of the interior of the larynx the operator, seated in front of the patient, has only to place in the fauces the warmed laryngoscope and direct a stream of light upon it. The most convenient position is for the patient to sit upright with the head leaning very slightly backwards. The distance of the physician from the patient should be such that the reflector brings the light to a focus, about the base of the uvula. With the ordinary sized reflector this will be from thirteen to fifteen inches. The lamp may be on either side of the patient according as the reflector is before the left or right eye of the observer. The flame should be about the level of the patient's eyes. The exact position of the lamp is a point of detail that is of little moment; for the observer soon learns so to place it as to receive the light on his reflector from which he can throw it in any direction. The light being thus under control, the patient opens the mouth as widely as possible; the rays are brought to a focus in the fauces; the laryngeal mirror is warmed, and at once so placed as to gently press the uvula backwards and upwards. The position of the parties is clearly shown in this engraving, which represents the simplest method of laryngos-

FIG. 10.

copy by reflected artificial light, and has been accurately copied from a photograph taken for me several years ago. It will be observed that no mode of controlling the tongue is here employed. Some patients, like the one from whom the photograph was taken, can completely display the fauces, holding the tongue well down all the time. In others, however, and they are the majority, the tongue involuntarily arches itself, and renders it impossible to see the fauces. To meet this inconvenience tongue depressors of various shapes were first of all employed. Those resembling a paper knife are the most simple (Fig. 11), but

FIG. 11.

like the double folding one (Fig. 12), they are unsatisfactory both for laryngoscopy and other purposes.

FIG. 12.

Before the discovery of the laryngoscope I had constructed an oval-bladed depressor, which holds the tongue firmly. The blades were of two sizes, and screwed into an ebony handle. The instrument is therefore portable. Türk's depressor is stronger, and for operative procedures more complete, but it is less portable. The patient can easily hold it in position himself. Voltolini's is also an excellent instrument.

My tongue depressor is the most convenient instrument for rhinoscopy, as the examination of the posterior nares by means of the faucial mirror is called.

For ordinary laryngoscopy the best plan is to direct the patient to put out his tongue, and for the operator to hold it gently but firmly with the thumb and forefinger covered with a small napkin. This prevents it from slipping, and a clean one can be used for every patient. It is not necessary to drag upon the organ, and the finger should be kept just above the level of the teeth to prevent their injuring its under surface.

It is absolutely necessary to warm the laryngeal mirror, or the moisture of the breath will at once condense upon it and obscure the view. It may easily be held for a few seconds over the chimney of the lamp.

When direct light is used a small spirit-lamp in any convenient position will serve the same purpose. The temperature is to be invariably tried on the back of the operator's hand, or on his face, for if it be so hot as to burn the patient he will naturally lose confidence in the physician, and perhaps decline a second attempt. In holding the mirror over the lamp a film of moisture momentarily condenses upon it, and at once clears off. It is then warm enough, but may be too hot. Hence the necessity for the precaution named.

The mirror, when warm, should be carried boldly forwards into the fauces, particular care being taken not to touch the tongue, as that will be likely to excite retching. The posterior surface of the mirror should push the uvula *without hesitation* somewhat backwards and upwards. There is no fear that this will cause irritation, while a trembling, hesitating way of holding it only produces an unbearable tickling. I have known many beginners utterly fail from tremulousness. The throat is far more tolerant of the contact of instruments thus suddenly pressing against it, than of the vibrations of a body held *steadily*. Of course force is not needed, but some degree of pressure is less intolerable than tickling.

To be continued.

Transactions of Societies.

DUBLIN OBSTETRICAL SOCIETY.

THE Society met at the King and Queen's College of Physicians, when the chair was occupied by the President, Dr. KIDD.

A resolution, expressing the great regret of the Society on the death of Dr. Beatty, was proposed by Dr. McClintock; seconded by Dr. Denham, and unanimously adopted.

Dr. KIDD having left the chair, and Dr. Byrne, Vice-President, having taken it, Dr. Kidd read a communication

ON FIBROUS TUMOURS OF THE UTERUS,

of which the following is an abstract:—

He remarked that in the books fibrous tumours are spoken of as of three classes. We have fibrous tumours found on the outer surface of the uterus, or sub-peritoneal tumours. We have them found in the substance of the uterus, or intramural tumours, and we have them found in the interior of the uterus, or intra-uterine tumours. The sub-peritoneal tumours are, as we know, the largest, and are very frequently numerous. There are cases recorded of tumours of this kind 70lbs. in weight. The chief importance of sub-peritoneal tumours arises from their size and their position. The remark has been made by Cruveilhier that the sub-peritoneal tumour is not accompanied by hæmorrhage; but a doubt has been thrown upon the absolute correctness of this statement. I now lay before you a uterus having on its outer surface a very small specimen of a sub-peritoneal tumour, not larger than a large-sized filbert; but there is a soft mucous polypus growing from the inner surface, at the fundus, and projecting into the cavity of the uterus, and there is also at the os-internum a number of cystic polypi. It was a case where we had a sub-peritoneal tumour combined with intra-uterine polypi, in which the fibrous tumour might have been recognized during life and the polypi have remained undetected. I can very well imagine that in such a case as this you might have a sub-peritoneal tumour complicated with hæmorrhage due to the polypus and not to the tumour. This, then, would afford a satisfactory explanation for the occurrence of hæmorrhage in connexion with sub-peritoneal tumours. I could not obtain any history of the uterine symptoms during life. The chief importance, however, of these sub-peritoneal tumours is from the mechanical inconvenience they cause. I have notes of a very remarkable tumour of this kind that I had the opportunity of observing from the beginning to the end. It was the case of an unmarried lady who consulted me for a tumour. It was then about the size of a goose's egg. A second tumour developed itself as I watched the progress of the case.

On examination, in 1859, I found a tumour of stony hardness; and on passing a sound into the uterus, I found this organ of the normal length and, as I have already mentioned, pushed upwards and forwards. The tumour behind the uterus increased in size so much, that there was a difficulty in getting the bowels to act, and at each menstrual period there was great pain in the tumour, and she suffered from great sickness of stomach. At no time was there uterine hæmorrhage.

In 1861, Dr. Churchill saw this lady. The whole of the upper part of the pelvis was occupied by the large hard solid mass, so tightly wedged into the pelvis as to be quite immovable; and the tumour rose in the abdomen to midway between the umbilicus and xiphoid cartilage. The constipated bowels and difficulty of defæcation continued. But the greatest source of complaint now was excessive pain along the course of the great sciatic nerve of the right side. Dr. Churchill suggested the use of an air-pessary strongly inflated, to bear the pressure of the tumour off the sacral plexus of nerves, and to gradually raise the tumour off the rectum. This was used for some months, and afforded considerable relief. The lady now went to the County Wexford, and was under the care of Dr. Isdell, who wrote to me that she had a fibrous tumour so completely blocking up the pelvis, that he thought defæcation would soon be impossible.

This is a very marked example of the mechanical inconvenience arising from this class of tumours. The pain in

the sciatic nerve was intense, and it was something frightful to witness her agony arising from it.

At the end of 1863, menstruation now ceased, and the abdomen gradually diminished in size; the pain and sickness of the stomach ceased; and the abdominal tumour disappeared without its going being in any way noticed, except from the diminution of size, which was so gradual, as to be only known by the result, and not by the process. The general health was greatly improved.

On 26th of June, 1867, I could not detect any tumour in the abdomen. On passing my finger into the vagina, I found a firm round tumour in Douglas' space. The uterus was easily felt, pushed a little forwards by the tumour, but nearly in its normal position.

This was one of the most remarkable cases I have ever known of the disappearance of a fibrous tumour.

The pressure here was upon the rectum and the sacral plexus of nerves, and the pessary afforded the patient great relief. In other instances the pressure is upon the urethra and upon the neck of the bladder.

The following case is an example of this:—A. D., an unmarried woman between forty and fifty years of age. During the last fourteen months had frequently suffered from retention of urine, and was obliged to have a catheter passed. On examination, a fibrous tumour was found growing from the posterior wall of the uterus, lying in the concavity of the sacrum, and forcing the uterus against the neck of the bladder. The tumour was fixed in this position. I tried unsuccessfully first to move it with my hand by placing my finger in the vagina and pressing it up. I then placed one of Barnes' India-rubber bags in the rectum and forced water into it by means of a syringe. As I forced the water into the bag it gradually lifted the tumour out of the pelvis, got it above the brim, and allowed the neck of the uterus to come down into its normal position. I then removed the bag, and placed in the vagina one of Hodge's pessaries. The woman complained, next day, that she had a tumour in the abdomen, which she had not had before. I have seen this woman frequently. The tumour is still in the abdomen, had not returned into the pelvis, and she never had any further difficulty in passing water.

Cases of this kind illustrate a remarkable circumstance—that the inconvenience arising from them, although mechanical, is intermittent. This woman suffered from retention of urine, but by means of baths she got relief, except on five occasions when the catheter had to be used. I think it is a remark of Dr. Charles Johnson, that a permanent obstruction of the rectum has never been recorded as arising from the pressure of a fibrous tumour, but you may have at intervals serious obstruction in the rectum. I think these tumours often become increased at the menstrual period. The first case, where pain in the sciatic nerve was always aggravated at the menstrual period, is a case of that kind. Another circumstance influencing them is the condition of the bowels. These tumours are also liable to become œdematous by being in some degree infiltrated with serum.

The increase of pressure by flatulent distention of the bowels was very forcibly brought under my observation in a case I saw with Dr. Gordon and the late Dr. Beatty. It was not, however, I believe, a fibrous tumour. The case was that of a lady who had been under Dr. Gordon's observation for a tumour occupying the left and lower part of the abdomen. In some way the bowels became obstructed, and she was for a very considerable period unable to pass anything from them. The abdomen became enormously distended, and we had all the symptoms of intestinal obstruction. We felt that if we once made an incision into the abdomen, and the intestines escaped, we never should be able to get them back again, so great was their flatulent distention. After trying many means to obtain relief, we passed a fine trocar into the transverse arch of the colon. A great escape of gas took place. The candle having been brought near, the gas took fire, and a blue flame was formed two or three inches in length. The next day the bowels acted freely, and continued to act for some time, until she gradually sank and died from other causes. It shows that flatulent distention of the bowels may cause a tumour to press on neighbouring organs.

The next point to which I desire to call your attention is the disappearance of fibrous tumours. In the case of the sub-peritoneal tumour that I have related, I believe the tumour disappeared by absorption. There was no escape of anything that could account for its disappearance.

Another change these tumours undergo is that of calcification, especially after menstruation has ceased. Reasoning on this, the use of chloride of calcium was suggested, and Dr. M'Clintock speaks highly of it. I do not know that I can give you an absolute proof of the diminution of tumours from the use of chloride of calcium, but the patients express themselves very much relieved by the use of it.

The next class of tumours are the intra-mural tumours. I have not much experience of my own to record with regard to intra-mural tumours. In my experience they are the least amenable to treatment, while they are the most serious, perhaps, to the patient. They cause sometimes great hæmorrhage. I had a case of intra-mural tumour, where I had an opportunity of dissecting the patient, and yet there was no history of hæmorrhage, even though the cavity of the uterus was much enlarged. In other cases not nearly of that size, the hæmorrhage was excessive. I believe the difference is owing to this—when the tumour is near the mucous surface, and presses on it, you have hæmorrhage; when it is in the substance of the wall of the uterus, and grows towards the outer surface, there will probably be no hæmorrhage. Many methods have been suggested for the treatment of these cases—incision into the capsule of the tumour, gouging, incision of the neck of the uterus, &c.

I have never seen a case where it seemed desirable to adopt these methods of treatment; and, indeed, they seem more likely to be useful in cases of intra-uterine tumours, which we now know can be removed. The injection of perchloride of iron has also been used to check hæmorrhage. That, in my experience, is the least useful and the most dangerous treatment. The last case in which I tried it proved fatal. The woman got a low form of metritis and died. Nitric acid does not produce nearly the same amount of irritation, and is more beneficial. The palliative treatment is of great importance in these cases, and the best form of it is plugging.

It has become the fashion of late to plug with cotton, and I have fallen into the way with others. It is a peculiarity of cotton, that as you wet it, it becomes contracted and occupies a smaller space than it did at first. When placed in the vagina it becomes wet with blood, contracts greatly, and leaves the vagina free enough to allow a discharge of blood. Sponge is the reverse of cotton; it expands when wet, and fills the vagina more completely. When the cotton plug is wet the blood will trickle past it; whereas the blood get into the interstices of the sponge and coagulates, and the hæmorrhage is arrested. There is one way in which cotton can be rendered more efficient, and that is by saturating the first portion introduced with perchloride of iron; this produces coagulation, and the bleeding is checked. And a more efficient method, when it can be managed, is to plug the os-uteri itself with a piece of prepared sponge.

Intra-uterine tumours may grow from any part of the uterus, but I never met with one growing in the canal of the cervix. They grow, in my experience, chiefly from the cavity or body of the uterus. My present experience of these tumours, where you have one side of the uterus bulged out, is that the pedicle of the tumour is attached opposite to the bulging part of the uterus. I have seen a number of these cases. So frequently have I met with this circumstance, that the tumour bulges out the wall of the uterus opposite to where it is attached, that I have ventured to predict where the attachment of the tumour would be found, and I have been, up to the present, invariably right.

The tumour I next exhibit was the first large-sized one I ever removed. In my operations for small tumours and polypi, I was in the habit of using for an écraseur a soft iron wire, and I thought there were advantages in using it. I attempted to remove this tumour with a soft iron wire and failed completely. My patient waited a few weeks, I tried again, and succeeded at the first effort in removing the tumour. I succeeded because I used a steel wire, a piece of piano string, in fact, which answered the purpose admirably. The long neck of the uterus is dilated with sea-tangle until the finger can go up, and the tumour is caught and fixed by a vulsellum. The soft wire when passed up assumes the shape of the canal of the cervix, and it is difficult to expand it again so as to get it round a large tumour. By using a steel wire you can compress it to get it through the narrow os, and when you get it up it expands by its own elasticity, and you can slip it over the tumour

with ease. The next large tumour I attempted to remove grew from the fundus of the uterus. So deterred was I by the difficulty I had experienced in using the soft wire. Turning it over in my mind, Dr. Barnes' suggestion to use steel wire for dividing the foetal head in certain cases of difficult labour occurred to me, and I determined to try it, and with it I succeeded in snaring the tumour and taking it away at the first attempt. She had been nearly dead when she came into hospital. In fact, she had been taken out of her bed and laid on the floor "to die easy," according to the superstition of the country, when Dr. Clarke, of Bailieboro', who was passing by, went into the house, plugged the vagina, and checked the hæmorrhage, and then had her sent to me. She is now perfectly recovered.

There is only one other point as to these intra-uterine tumours which I wish to speak of. Sometimes they are removed by nature. In one of these cases I found signs of a considerable tumour in the interior of the uterus, and I made arrangements for the removal of it. An appointment was made for the operation, and some friends were requested to join me. I happened to have a very fatiguing case the night before, and begged to be allowed to postpone the operation. It was accordingly put off. That night the lady had a rigor. The next morning her pulse was 150, and she was in high fever; and she remained in this state for a fortnight, and at its termination this mass was expelled. There was no return of hæmorrhage, and she went home to the country comparatively well, and the uterus greatly reduced in size.

The Vice-President, Dr. BRYNE, said: He had never witnessed a case where a tumour was expelled by natural processes alone; but he had come across cases in the dissecting room where these intra-uterine tumours had undergone calcareous degeneration, and in which, if the patient had lived longer, the tumour would probably have been expelled. There was one great cause for satisfaction in respect to these tumours, that except they assumed the form of polypi, when the menopause occurred, the hæmorrhage caused by the tumour ceased. He had under his observation the case of a lady who was blanched with hæmorrhage, produced by a large fibrous tumour. She was several times on the point of death, but when the menopause came the hæmorrhage ceased.

Dr. DENHAM: He remembered a patient who was in the habit of coming to the Rotundo Hospital. She had a large fibrous tumour in the anterior wall of the uterus, and she came to the hospital suffering from retention of urine. They always drew off a quantity of healthy urine, and every month or six weeks the operation would have to be repeated; but why the retention came on at any particular period they could not tell. He believed she was still in the habit of going to the hospital, and the tumour was progressing slowly in its growth. There was one form of danger from these tumours in the substance of the uterus which had not been alluded to—the possibility of a woman thus affected proving pregnant. He remembered a lamentable case of that kind. A large, stout, healthy woman, 30 years of age, proved pregnant. Unfortunately for her there were several of these tumours imbedded in the body of the uterus. She had a tolerably healthy labour, and the child lived, but she died from flooding, it being impossible to produce contraction of the uterus.

He quite agreed with Dr. Kidd as to the inefficiency of plugging. He had very little faith in it. He thought they could not plug the os better than by putting in some pieces of sea-tangle, and applying nitric acid to the tumour itself. Spontaneous separation of the tumours was a process they could not wait for. It was an event of such rare occurrence that no sane man would wait for spontaneous cure when his patient was suffering from repeated hæmorrhage. He had not the apprehensions Dr. Kidd entertained as to the preparations of iron.

Dr. ATHILL bore testimony in favour of the steel wire, the use of which had been introduced into Dublin by Dr. Kidd. He considered it superior to any other material for performing *érasement* they could possibly use in these cases. With regard to the point of attachment of these tumours he was not quite sure that he could accept the proposition that a tumour bulged out of the portion of the uterus opposite its apex, instead of the portion corresponding to its attachment.

• He was not altogether in accordance with Dr. Kidd in re-

spect to plugging. No doubt the most efficient way was to plug the os-uteri by means of sponge tents, but that was difficult to do when the woman was bleeding rapidly. He preferred the cotton, and he had found it tolerably effective. He first introduced a piece of cotton saturated with perchloride of iron and glycerine, next, a piece saturated with pure glycerine, and next pieces that had not been saturated at all. When cotton did not succeed it was often because it was not properly employed. His objection to the sponge was threefold. First, the difficulty of introduction. The next objection he had was the horrible stench it caused. His third objection was the expense. With respect to the internal application of nitrate of silver, nitric acid, and perchloride of iron, he agreed with Dr. Kidd. The only severe case of pelvic cellulitis he had ever seen was brought on by perchloride of iron.

With respect to the effects of pregnancy and menstruation on these tumours, it was a matter of great importance. A woman, known to have a fibrous tumour, who was about to get married, consulted him as to the propriety of doing so. He gave a strong opinion against the advisability of that course. It was clearly proved these tumours enlarged much during pregnancy, and gave rise to very grave symptoms, endangering the patient's life.

Dr. KIDD said he might, had time permitted, have ventured to adduce some cases of fibrous tumours complicating pregnancy. He had seen two women die soon after labour from the effects of sloughing and disintegration of fibrous tumours in the uterus. He remembered another case. The students who attended her thought she had twins, and after waiting for some time for the second child, sent for him. To clear up the doubt that existed, he introduced his hand, and found a large fibrous tumour in the fundus of the uterus. He went back to see the woman occasionally, and on the fourth day he saw her up, and washing clothes. Two months afterwards the uterus had gone back to its normal size. He had three times attended a lady who had a large mass of sub-peritoneal fibrous tumours, they lay high up in the abdomen, and never affected her labours, and he had, during a previous session, brought before them a case where a large tumour completely blocked up the brim of the pelvis and prevented the entrance of the head. In that case he succeeded in putting the tumour up into the abdomen by using one of Barnes' bags in the method he had alluded to in his communication.

BRITISH MEDICAL ASSOCIATION.

ADDRESS IN SURGERY.

BY

OLIVER PEMBERTON, Esq.,

Surgeon to the General Hospital, and Professor of Surgery in Queen's College, Birmingham; Foreign Corresponding Member of the Society of Surgery of Paris; etc.

(Continued from page 152.)

Up to the early part of the year 1868, I had invariably performed the lateral operation of lithotomy in all cases and at all ages, and had encountered that good and ill luck that always, sooner or later, disturbs the statistics of the most successful or the most unfortunate of operators who take all that come before them. I had reached my sixtieth case. Of this number, thirty-five were under twenty years, and but one had died from the operation—a child of four, a complicated case, with stone both in bladder and urethra. Of the remaining twenty-five, four had died at 79, 59, 56, and 53. Surgically, there was nothing to be regretted concerning these, save their deaths; for about them all were conditions favouring a bad rather than a good ending—conditions that happen with stone, at all times, and to all people, and will happen again; so I need not touch on them further now.

In all this I had used the single knife and the laterally grooved staff, and I did not think then I should use any other instruments as long as I continued to operate. But what happened? I cut a boy of eleven, and extracted an ordinary-sized stone, without, apparently, complication of any kind. Hæmorrhage followed, of such severity that it was with difficulty controlled, and death from its immediate

effects took place within twenty-four hours of the operation. I could find nothing in the *post-mortem* examination to account for the bleeding. It is true he had but one kidney, but that had nothing to do with his death. It was then clear the cutting did it somewhere; and I naturally thought I should like, in the future, to extract such a stone as the one I then removed with less of the cutting in the dark, if possible. Accordingly, I turned to median lithotomy. Allaiton, who practised near here, had delivered a lecture on the subject of lithotomy simplified, in the Sydenham College, in 1854; and I was much struck by his arguments as to the capability of dilating the neck of the bladder without incision. I felt satisfied that, for bladders within reach of the finger, and for small stones, if not for all, there should be escape from the fear of uncontrollable hæmorrhage, though I had never tested his proceeding in the living subject. Since, I have had an experience of twenty-five cases. Of these, twenty have been of ages from two to twenty years, with not a single death. Of the five, of ages from forty-six to sixty, one died of peritonitis.

I perform the operation in the following way: I open the urethra, just behind the bulb, on a centrally grooved staff. Along this, I pass into the bladder a tapering probe-headed gorget, withdraw the staff, and, taking hold of the handle of the gorget, pass the finger gently along its groove into the bladder, letting it dilate as it goes, and so take the place of the receding guide.

Now, I know that many believe that this dilatation means laceration. It has, indeed, not very long since been described as "complete rupture and laceration" (Mr. Teevan: *Lancet*, vol. ii., 1870, p. 237), and as "unsurgical and dangerous." I answer this statement, which I venture to characterise as eminently reckless, by a positive contradiction as to fact.

I have cut enough cases by the ordinary lateral method, and am still cutting them, to know the difference between laceration and dilatation. I am quite satisfied that my finger passes into the bladder without laceration in the operation I have described. I feel the entrance gradually narrow itself into a mere ring, which encircles and equally grasps my finger on all sides. Through this ring pass the forceps; through this ring passes the stone, and any number of stones, or any fragments of stones; and there is no laceration, unless the stone be too large for the proceeding, or violence have been used.

I hold that it cannot be necessary to make incisions to the same extent to remove a body of the size of a pea, as we should make for one of the size of twenty peas; and, further, my conviction is that, whilst in all ordinary dangers, the median operation as compared with the lateral, is simply equal, in two it is immeasurably less. These are the dangers from hæmorrhage, and from prolonged recovery. The danger from hæmorrhage in the median operation can only arise from a central wound of the bulb. It is not unlikely to take place, and did occur to me once in the twenty cases, and was readily arrested; for it must be borne in mind that the source cannot be far away, and so happily cannot require the use of that most hateful of all appliances—a plug for the wound. As to recovery, the exception is to find any constitutional disturbance at all. The urine is retained and passed naturally. I would like to ask if any one ever knew a patient pass his urine naturally with a "lacerated" neck of bladder? and the wound is healed mostly within a fortnight.

I shall be prepared for it to be said of my advocacy of median lithotomy—"The statistics of your own cases are against you." My answer is, "Statistics are not everything." A case may end just as successfully one way as another, though the troubles on the journey differ widely, and no one will question that lateral lithotomy in children is eminently successful. But every operator who has sufficiently tried any given two methods of procedure, has a right to say which of the two he prefers; and therefore it is that I say, when I reflect on the anxiety that I endured in watching the threatenings of mischief in children cut by the lateral operation, I rejoice that I have cause for it no longer, notwithstanding the general good fortune that attended my practice with that method.

And now as to the cases where the median operation should not be selected. In any instances where the finger is not likely to reach the bladder, so that instrumental dilatation would be required, the lateral operation should be preferred. The reason I use my finger is because I have more control over it than over an instrument. I can regulate the one, not the other. I would sooner cut than lacerate at any time, and

I consider that the use of instrumental dilatation in this operation means laceration. You may use it, on and off, with impunity, but it is a most destructive instrument—reviving all the dangers of the discarded Marian. I attribute the peritonitis, which carried off my single fatal case, solely to the laceration of the neck of the bladder that of necessity followed its use. I repeat, the only dilator must be the finger, and so long as the neck of the bladder can be widened by this sufficiently to allow of the removal of a stone without laceration, I shall deem it a part of my duty to advocate the adoption of this form of median lithotomy.

I hope, however, my observations will not be misunderstood. I am second to none in admiring what Cheselden practised, and what Liston and Ferguson have brought to perfection—the lateral operation for stone. I have been surrounded during the whole of my professional life by teachers and colleagues who have had unusual opportunities for practice, and who have realised brilliant successes in this very operation; but, in my opinion, it is not most desirable operation to perform for all stones, at any age and under any circumstances, as some would have us believe.

I now desire to say something about stricture of the urethra. It is to me remarkable, but it is true, that the views entertained by the highest surgical authorities of the day, differ on no subject so widely as on the particular system they adopt and recommend in the treatment of stricture. Simple dilatation and rest, I am thankful to say, have had a great following, and, if I mistake not, will yet rise into higher position. The main quarrel is between the advocates of internal as opposed to external division. The late Professor Syme (*Stricture of the Urethra*, p. 21, 1855) thought he had effectually put an end to the use of those "dreadful engines," as he termed M. Reybard's instruments; but he was mistaken, for strictures of this day are both cut, split, and torn; and new engines for the purpose multiply, as if the great surgeon had never lived to speak of plunges in the dark with caustic, or of ripping open the urethra by internal section.

Stricture may fairly be defined to be a diminution of the normal diameter of any portion of the urethral canal; and as it must be admitted that the existence of any stricture, however slight, from whatever cause proceeding, and of whatever nature, may sooner or later give rise to serious consequences in the condition of either the bladder or kidneys, it is needful for the surgeon to discover it and cure it as soon as possible. But the real question is in reference to this word cure. Have we to deal with a simple stricture that has resulted from inflammation of the lining membrane of the urethral canal, or with a stricture, originally of this kind, which has been aggravated and increased in extent by ill-considered surgical proceedings?

For the first, there is a cure by simple dilatation. For the second, there properly is no cure. Once organic stricture, always organic stricture, is my belief. Whenever the lining membrane of the urethra has been injured, whether by accident, disease, or by bad surgery, the spot will contract and establish permanent stricture, and I do not believe that the materials constituting such cicatricial narrowing are ever absorbed.

If you endeavour to restore the normal calibre of the urethra under these conditions by ever so well considered a system of dilatation, my opinion is that the contraction will return sooner or later with increased vigour, the natural elasticity of the canal being gone; in other words, dilatation will not effect a cure, and never does effect a cure.

But dilatation, if it be well and properly carried out, will protect the patient against the occurrence of those diseases which, dependent on individual health and mode of life, arise either rapidly or slowly in all cases of stricture. The degree to which it is necessary to carry this may fairly allow of discussion; for I have ever before my mind the conviction that the very means made use of to effect the so-called cure, may become the certain cause of the continuance, and, in many cases, of the increase, of the malady.

I think it will be admitted that the tendency to narrowing in cases of stricture, differs very markedly in individuals. Some may show few signs of change during many years, others, especially those arising from the effects of laceration by direct violence, certainly, surely, and often rapidly increase. In all cases, treatment by dilatation is necessary; but I doubt myself whether it is needful always to endeavour to restore the standard of the canal to the utmost of its original extent. I believe that there are many cases which admit of being maintained at a standard short of this, depending, however, on the facility with which the contraction yields, and its rate of increase sub-

sequently. And it must never be forgotten that when once this treatment by dilatation has been commenced—no matter how carefully or how thoroughly it may have been done—it will have to be continued, whether at the hands of the surgeon or of the patient, more or less during life.

For my own part, time being given, I do not believe that there is any stricture through which an instrument cannot be passed by a skilful surgeon. This being so, treatment by gradual dilatation follows; and in my judgment this should be by the silver catheter, as the safest, simplest, and most certain instrument in the greatest number of hands yet given to us, *bougie à boule* and *bougie olivaire* notwithstanding. If the induration be cartilaginous non-dilatable, or if there be fistula, the treatment by external division on a grooved staff should be adopted as speedily as possible.

Entering this view of the permanence of the changes established in the urethra by injury or disease, I am not very likely to favour any internal severance of the lining of the canal, whether by Mr. Holt's method of so-called "splitting," or by any form of internal cutting. I believe a wound is produced just as much in the one case as in the other. I regard these methods as artificially inducing the very conditions which I lament should result from almost unavoidable causes; and I further believe that a shut-up wound on the internal face of the lining of the urethra, is attended by dangers, from which an open wound on the outside face is comparatively free (a). I have had occasion to divide the urethra after Professor Syme's method in upwards of thirty cases. In one case only was there a fatal ending, and this from pyæmia. In no case was there a relapse, provided that an instrument was passed from time to time, the frequency of this being determined by individual tendency to re-contraction, once a month to once in three months being about the average; and by this means the calibre of the urethra was without difficulty maintained at its original standard. All the cases that I have seen, save one, have required this continued resort to dilatation, and will require it, in my judgment, more or less, during life. For there is no more a cure by this, than by dilatation or splitting. In the case that did not require it a fistula remained permanently in the perineum, letting through a little urine, the general stream flowing by the urethra, which at the end of twelve years shows no disposition to contract.

If the induration of the urethra, and narrowing, be of such an extent as to preclude the idea of dealing with it by external division, I prefer to tap the bladder by the rectum. I do not feel inclined, at present, to divide from the bulb to the meatus; and this literally must be the length of an incision in many of these long-standing cases, if the entire disease is to be dealt with.

There are numbers of these inveterate cases wholly unsuited to external division; but they are eminently calculated to be dealt with by a method which deviates the course of the urine to another channel, in order that rest may heal the fistulae, and absorb much of that adventitious material blocking up the natural urethra, which can then readily be found, and have a standard established almost without resort to dilatation.

I frankly say that I do not believe that either internal or external division of any urethra will cause the healing of fistulae in the groin, buttock, and perineum, where a man passes his urine, as it has been graphically described, like a watering pot. (See Discussion: Medical Society of London: *British Medical Journal*, November, 1870, p. 590.)

Surely, relief by the rectum will stand comparison with all the manoeuvres that have been suggested from the days of Hunter to Grainger, and from Grainger, who, by-the-by, belonged to us here, to Gouley and Wheelhouse. I cannot conceive why a patient is to sustain—sometimes for hours together—the distress belonging to hopeless attempts made to trace, in that stage of the disease, an impracticable canal, when the chief cause of the malady—the flow of urine—can be reached and diverted in a moment. Since Mr. Cock published his views (*Medico-Chirurgical Transactions*, vol. xxxv., p. 153), now just twenty years ago, I have had many opportunities of seeing the results of this proceeding.

I am able confidently to state that it is wholly free from danger. Indeed, I can scarcely conceive death following as a direct result of the operation. So little fear of the proceeding had one of my patients that he has been tapped at least six

times for the relief of fleeting attacks of retention, dependent on a rapidly distended bladder, unable to empty itself in the presence of long standing organic stricture. I have seen him almost within a day or two afterwards as if nothing had occurred. Further no fistula remains, for the opening in the rectum invariably closes after a few weeks.

I have left in the silver canula for three weeks, and have not found inconvenience from its presence; indeed, it appears to me that one of the greatest arguments in favour of its adoption exists in the fact of the position of the canula, which, whilst certainly securing the emptying of the bladder, is wholly removed from the urethra. I am strongly myself of opinion that many urinary cases terminate fatally from urethral irritation, set going and kept up by an instrument retained in the canal in its length.

Some persons are very tolerant of tied-in catheters, whilst others, dependent on a certain idiosyncrasy, cannot sustain with impunity the simple introduction of an instrument. I saw a case in a young man which all but ended fatally from epileptic convulsions, induced by a first catheter; whilst the single introduction of a lithotrite in a man of 77 to measure a large smooth stone that had been carried with impunity for years, set up such an attack of cystitis that death ensued. I was very much impressed by a case in which a man, suffering from complete paralysis from the bladder downwards, owing to concussion of the spine, had a silver catheter tied in his bladder. He appeared sinking fast, and the most profound irritation of the bladder was established. I directed the urine to be drawn off every eight hours, and he began from that moment to amend, and ultimately recovered. Here, doubtless, the true explanation lay not in idiosyncrasy, but in the fact of the existence of disease from the injury. You may leave an instrument in the bladder for years from the perineum, but you cannot do this with impunity and traverse the length of the urethra. Morbid sympathies become excited in connection with the urethra, which are not produced by the introduction of instruments into other mucous channels.

In what I have said, I have urged the adoption of tapping by the rectum, as affording assured relief to the most inveterate forms of stricture. And in considering the treatment of this disease, I have hitherto limited my observations to cases of stricture of the urethra *per se*, not to those complicated by retention of urine. I must equally urge it, however, as the remedy most reasonable for almost every form of retention. It is the absolute cure of spasmodic stricture; and if, in any given case arising from this cause, after one good effort has been made to obtain relief by ordinary means, there is no success, it should be carried into effect. If retention be present with an impermeable urethra from organic stricture, a double necessity supports its selection, whilst I have yet to learn that it is inadmissible in the retention of old people from enlarged prostate. I know that it can be accomplished in these cases, but of course not so readily as if the rectum had only its ordinary contents; and I am quite satisfied that far less irritation would be produced in the majority of these diseases, where death so often directly results from the effects of instrumental measures, by the presence, at the most depending part of the bladder, of a harmless tube, calculated to secure the removal of all urine secreted, and thus master that inevitable decomposition which is not overcome by any other method in use, for the simple reason that one and all fail to empty the bladder. If the membranous urethra bulge behind a stricture, or if an abscess opened in the perineum suggest a ready path to the bladder, by all means let a female catheter effect, through the perineum, what otherwise, I maintain, can be accomplished by the rectum.

Some years ago I asked the question, "Can the urethral canal be permanently restored whenever any complete and considerable portion of its length has been entirely destroyed?" I believe the answer must yet be "No." I had then a boy of sixteen, with at least two inches completely destroyed by burning; and, believing this, I established him with a silver perineal tube, through which he now (aged 27) passes his urine without trouble; but there is nothing in the growth of the parts that tempts me to interfere, for I know the whole circle of the canal must be gone.

I think, however, that if only a streak of mucous membrane lingers about the part, an efficient connection can be re-established even after the lapse of many years.

I saw in the early part of this year a patient, aged 30, who had sustained, eighteen years previously, such a laceration,

(a) I will, with Sir H. Thompson, admit its use in narrowings at the external meatus.—*Pathology and Treatment of Stricture*. Third edition.

that two inches below the meatus was a fistulous opening into the urethra, three-quarters of an inch long. The canal was pervious from the meatus to about one inch above the bulb, where was a second small fistula; then, the canal was obliterated for an inch, and a third fistula, placed just at the commencement of the membranous division, gave exit to all his urine. For eighteen years, then, the urethra from this spot had been unused. I first closed the penile fistula, paring the edges, which looked beautifully in apposition for some days, and then came apart as usual. But by clipping the penis with a self-acting spring, on the principle of the *serre fine*, the edges were admirably united. Then I laid the lower fistule into one, dividing all the hard textures between them, and passed an eight catheter, and for forty-eight hours tied it in the bladder. After this I passed nine daily. The patient learned to pass it in a week himself; and at this time the canal is in excellent order, with the introduction once a week. Now, I do not think the roof of the urethra was destroyed here, and hence the reason of a success which I did not expect.

In reference to the repair of penile and scrotal fistule, I would remark that they can alone be treated satisfactorily by the urine being drained through the rectum, or, as here, through the perinæum. Even then, union by first intention is a myth; but union can be obtained by keeping the granulating edges together by some artificial means, at the same time that vivacity is maintained in them by the use of the acetum lyttæ.

ADDRESS IN MEDICINE.

By SAMUEL WILKS, M.D., F.R.C.P., F.R.S.,

Physician and Lecturer on Medicine at Guy's Hospital, Examiner in Medicine at the Royal College of Surgeons, &c.

In the first place, I shall declare to you that I have no conservative feelings in respect to doctrines and practices in our Profession which have long gone by, but have a strong faith in progress. As everything having a scientific basis must naturally grow better, so, I take it, must medicine. The question is probably hardly worth discussing; for I have ever found that, in whatever department of life the subject lies, the clinging to the past on the one hand, or the readiness to embrace a novelty on the other, resolves itself into a question of feeling; and against sentiment, as you all know, there is no appeal. For myself, I have the liveliest sympathy with every fresh impulse given to the onward movement of our art; but there are those who are well content with the present, and even look lovingly on the past. I am old enough to have seen with my own eyes the gentleman who smiled at Laennec, and made his stethoscope a bouquet-holder. I have heard living men in scientific societies denounce the microscope as an useless instrument; more recently I have heard the sphygmograph spoken of as a pretty plaything; and, more astonishing yet, my own favourite pursuit, the dissection of the dead, declared to lead to no living results. It is impossible to leave untouched this standstill condition of the human mind, for reason of some of the astounding propositions which have arisen out of it. To me it seems that no advance, no progress, is possible to be asserted, unless we are capable of comparing the past with the present; but immediately we set about the task, and speak, for example, about the treatment adopted in former days in connection with that of the present, and point out to the seniors of the Profession that their change of practice and adoption of new modes of cure is a sign of the advance of the times, we are met, not by a denial of the fact, but by the assertion of a most wonderful doctrine—viz., that the change is not in them, but in Nature, and that they have accommodated their treatment accordingly. It does not seem to have occurred to them that science and art are continually on the march, and that there is more knowledge of clinical medicine and pathology than when they were young; that reports of cases are more accurately taken; and least of all do they suspect that their own minds regard the events of their youth with a fonder gaze than the facts of the present day, but lead themselves to believe that the art of medicine which they now practise is in no way preferable to that of times gone by; and that they have simply changed their procedure in accordance with the alteration of the type of mankind. It seems far more probable to them that man, having existed on the earth for six thousand years (according to orthodox notions), should alter his type in the course of one generation, than that they could have in any way erred in the early practice of their profession. To my mind, this is one of the most preposterous

doctrines ever started in order to save the consistency of a few individuals. Why, if our material be thus changing, it is not safe to practise, for we can never be sure of our results; and thus it may happen, as I was but lately told when I showed how people could lose blood with equal impunity as their forefathers, that perhaps the type was again relapsing into its former dignity. It thus becomes often very difficult to distinguish between absolute truth and the offspring of the human brain. The future professor may be unable to decide, when studying our literature, whether certain diseases were prevailing at certain times, or whether they were merely fashionable complaints of the hour. He may at one time read of fibroid phthisis, at another of ataxia; and he may wonder whether ulceration of the womb, which was once so common, and has now given way to displacements of the organ, shows how disease flows in waves or merely represents the undulations of the Medical mind.

With regard to our general notions of disease, I consider that, during the last few years, our opinions have made a rapid advance. I naturally take the period during which I have been in the Profession, and reflect upon what was implanted in my own mind by lectures and by books twenty-five years ago. Of course it is necessary to remember that, as our ideas are matured, there is a great liability to transfer one's own earlier and cruder notions to the teachers whom we misunderstand; but, allowing largely for this explanation, I cannot but think that the last twenty or thirty years of pathological progress must have made material alteration in our general opinions regarding disease. For example: a common method of teaching was by the description of acute inflammation occurring in healthy subjects; but the disappointment I felt, in common with other students, in not seeing these cases in the wards of the hospital, soon convinced me that something was wrong. We saw abundance of chronic disease, occasionally an acute affection; but this was generally patched on to some other chronic disorder; so it soon became evident that, with the exception of acute affections of the chest due to vicissitudes of weather, an acute inflammation occurring in a healthy person was of the rarest possible occurrence. Morbid anatomy has been mainly instrumental in making the discovery; and, in fact, this could not have been reached without its aid, since apparently sudden and fatal illnesses were constantly occurring in persons of previously good health. It is true, for example, that persons died of acute peritonitis, and, without *post-mortem* examination, the cause was attributed to that universal evil, cold; but inspections have now invariably disclosed some old and long latent mischief in an organ which lighted up the fatal attack. To suppose that a healthy person can suddenly have an acute arachnitis or acute peritonitis, may, perhaps, involve an actual pathological absurdity. Even the acute inflammation of the chest occurring in healthy persons under the aggravated causes of wet and cold, is far less common than is generally supposed. When, many years ago, a paper was read at a Medical society advocating the early treatment of acute disease lest it should become chronic, I took the opportunity of remarking that an opposite suggestion might have been with more propriety advanced—viz., the advantage of arresting chronic processes lest they should become acute. There are far more acute diseases carrying off chronically diseased people, than there are chronic diseases which have had their origin in acute affections. What we might more advantageously direct our minds to, are the insidious and slow-working changes in the organs and tissues, to see if we can grasp these in their beginnings and check them at their source; what we are too often asked to do, however, is to arrest an acute inflammation, which is an evidence only of the beginning of the end. But this is what we see through all Nature. If events appear sudden, they are but the exponents of some long anterior hidden causes. The fires of Vesuvius have long been smouldering below before they issue from the summit; and the earthquake is only the result of the pent-up gases arising from chemical changes which have been slowly going on in the bowels of the earth. In society, an honest person cannot possibly become on a sudden a thief, nor a contented people suddenly break out in rebellion. A sane man cannot in an instant become mad; and, as was observed in a late celebrated case, the event which brings the person to justice is but the sudden explosion of distorted feelings long dormant in the brain, but immediately excited by some trivial event. Although I say these are views which have been greatly promoted by the advance in pathology, yet the more profound observers had a glimpse of their truth, as had the father of medicine himself; for Hippocrates says,

"Diseases do not fall upon men instantaneously, but, being collected by slow degrees, they explode with accumulated force." I believe, in teaching, there is no more important fact to impress upon the minds of students than that diseases come insidiously and slowly; and the circumstances which induce them are those most worthy of attention. When the older text-books spoke of attacking acute disease in a healthy subject, it appears to us almost as Quixotic as making a thief suddenly honest, or making the French a tranquil people by a new form of government.

In studying how various morbid processes are produced, several circumstances have to be considered, more especially the mode of life which favours them, and the original temperament of the individual, which renders him more susceptible to certain agencies than to others. I consider it to be no credit to our Profession that the doctrine of temperaments has not been (with one or two exceptions) more systematically taught in our schools. The value of it, however, is tacitly acknowledged in the importance which the man of acumen and experience attaches to the general appearance of his patient; he sees at a glance when the patient enters his study that he is about to hear a story of a nervous affection, or of symptoms evincing a proclivity to phthisis, or of troubles showing that the patient belongs to the gouty class. He may have nothing more than a rule of thumb to help him; but his experience informs him that the world is composed of different varieties of persons, that each is inclined to morbid changes in a given direction, and that the tendency to particular changes may be dormant, but that the exciting causes are ever waiting ready to awaken it into action. A question here arises, whether these predisposing and exciting causes of disease are not the same. For example, let us take the so-called gouty condition of body, which is said to prevail more in England than in any other country; and let us assume the correctness of the ordinary theory, that its cause is to be found in the use of malt liquors, strong wines, and nitrogenous food. What we understand by this is, that these conditions, operating through several generations, induce this peculiar diathesis. Now, if this be so, it seems reasonable to infer that the same causes acting in excess in a peculiar individual so predisposed, will develop in him all the outward manifestations of the disease; and, on the other hand, the avoidance of such causes would be the means of retarding their development, so that the predisposing and exciting causes would be one. Let us take another example of a diathesis which our climate is prone to produce—the tubercular. It is generally believed, from the peculiarities of its distribution on the globe, that cold and moist air, together with certain circumstances of civilised life, are mainly instrumental in the production of the diathesis. These causes operating through several generations will produce the consumptive tendency; at the same time, these identical causes are they which induce the disease in a predisposed individual; and, on the other hand, the avoidance of them is the mode by which we hope to arrest the disease. The same reason is applicable to other forms of temperaments; and it thus becomes a subject of interesting speculation to inquire under what circumstances they were all developed. In our own country we have to take into consideration the mixture in our race of Norman, Saxon, Dane, and Celt; but, at the same time, it is evident that soil, food, and climate are instrumental in producing striking peculiarities. It is a remarkable fact, and one which I have not been able to unravel, that one country should produce two such different temperaments as those which I have chosen as examples; the one tending in disease to the production of gouty phenomena, and the other tending to consumption. Belonging to the first class is the model Englishman, a good example of whom may be found in the late Lord Palmerston. I allude to a man of sanguineous temperament, with great activity and energy, both of mind and body; a man ready for all emergencies, full of pluck, plenty of "go," of social habits, good humoured, and inclined to gout. It seems remarkable that, with the production of such men, of whom the country is for the most part proud, we should develop, also, the individual inclined to consumption. He or she has often a beautiful conformation of body and a fine intellect, although different from that which I have just described, being more susceptible and refined. It may be that such persons are overbred. They certainly are inclined to die early, but often not before they marry, and propagate their kind. If this were not so, it is probable that the sickly race would be kept under, and, in a more natural state of society, would actually die out; that is, where there were no doctors; for the artificial aid

so strenuously given to keep alive the ailing individual, tends to preserve its existence. Therefrom arises another large question which must constantly obtrude itself upon the mind of the Medical man—Whether he is not interfering with the natural laws of the world? I confess I do as others do, shut my eyes to these speculations, and do that duty to my fellow creatures which is closest before me—attempt to relieve their suffering; yet it cannot be gainsayed that, if the Darwinian doctrines be in any way true, they are applicable to the *genus homo* as well as to any other race of beings; and that we, by preserving the puny, the wretched, and deformed, are assisting in the degeneration of the race. Thus Herbert Spencer has remarked, in reference to the care taken of the miserable, "instead of diminishing suffering, it eventually increases it. It favours the multiplication of those worst fitted for existence, and, by consequence, hinders the multiplication of those best fitted for existence, leaving, as it does, less room for them. It tends to fill the world with those to whom life will bring most pain, and tends to keep out of it those to whom life will bring most pleasure. It inflicts positive misery, and prevents positive happiness." Philosophers have thus, without reference to general zoological laws, seen the importance of cultivating the race by allowing the weakly to drop out; and thus long ago it was observed that the Scotch had probably preserved their hardihood on account of the privations which cut off their sickly young; in the same way as among the lower animals it is known that, where the conditions of life are hardest, there the strongest individuals prevail. We can, therefore, scarcely shut our eyes to the fact that, if we were able to preserve all those miserable creatures the lives of whom their parents would give a fortune to save, we should be instrumental in causing a deterioration of the race. It is thought that, where instinct guides and more natural laws come into operation amongst the lower animals, intelligence would serve the same purpose in man. Thus Joseph Adams, who wrote on hereditary disease at the beginning of the century, says: "In a state of nature, the race of all gregarious animals is progressively improving as far as is consistent with the capacity for improvement. The strongest male becomes the *vir gregis*, and consequently the father of most of the offspring. In the ruder state of the human society, or, rather, in its earlier formation, something of the same kind may prevail; but, in a more advanced stage, sufficient provision is made by the preference which health and intellect will for the most part produce in either sex." Such prudence, however, is so little to be depended on, that it probably has little avail in the union of the sexes; and this gives rise to such views as are expressed by Mr. Phœbus in *Lothair*, when he says, "It is the first duty of a State to attend to the health and frame of the subject. The Spartans understood this; they permitted no marriage the probable consequence of which might be a feeble progeny; they even took measures to secure a vigorous one. The Romans doomed the deformed to immediate destruction. The union of the races concerns the welfare of the commonwealth much too nearly to be entrusted to individual arrangement. The fate of a nation will ultimately depend upon the health and strength of the population. Both France and England should look to this; they have cause. As for our mighty engines of war, in the hands of a puny race it will be the old story of the lower Empire and the Greek fire. Laws should be passed to secure all this; and some day they will be."

Some philosophers, when contemplating the scarcity of individual life compared with the myriads of germs which are destroyed, have seen in epidemics a mode by which population is kept under, and have a kind of belief that Nature is not to be cheated of her victims; for, if man should devise the means of escaping from one plague, he will be overcome by another, although it appears under a new guise. We cannot, however, concur in this speculation, disagreeing, as we do, with philosophers, that the sickly are especially selected for removal. I shall presently show that is not the case. We might, perhaps, endeavour to reconcile these high speculations with the antagonistic interference of the Medical man, by making it our duty to study more the different temperaments of the race, and endeavouring to discover those causes which tend to develop them and their necessary morbid sequences. We might thus perchance arrest the tendency to disease; and the highest office of the Medical man would be that of custodian of the

public health. This is one, I might say, which he has already voluntarily assumed; and with that exalted view of his functions which, I am glad to say, animates our Profession, he is always found battling with disease at its threshold, and endeavouring to arrest epidemic disease at its source. In a lesser manner, he should endeavour, in his own professional circle, to watch the dispositions and manners of his patient, and thus he may be able to advise and guide the children belonging to some of the temperaments before mentioned into those positions of life which would be most advantageous for them. The doctor is shown the precocious child by the fond parent, who discerns nothing but robustness in its mind and body; but he, with the eye of knowledge, sees already the latent tendency to disease; he may be able to destroy the seeds which might afterwards develop, or, should he not be able to prevent them striking root, he may arrest their further growth, even though it be true that we are born to die; for, as the poet says,

"As man, perhaps the moment of his breath,
Receives the lurking principle of death,
The young disease which must subdue at length,
Grows with his growth, and strengthens with his strength."

Although an older than Pope had already said,

"Nascentes morimur, finisque ab origine penitet."

I have already said that the body has hereditary tendencies to morbid changes of special kinds, rather than to mere accidental diseases, and, therefore, that the various tissues are liable to their own peculiar degenerations. When we speak, for example, of a gouty man, we imply much more than his liability to an attack of arthritic trouble; he may have, or not, a *materies morbi* in his blood, but he is liable to temporary and organic derangements of a given kind—such as granular kidney, diseased heart and blood vessels, articular inflammation, and gravel. In tuberculosis, in like manner, there is a tendency to changes in the epithelium of the cutaneous or mucous surfaces, whether bronchial or intestinal. In the nervous temperament, the nervous system is liable to be thrown into unstable equilibrium. But not only in hereditary, but in acquired diseases, we find that the morbid changes are of a particular kind, and that special organs and tissues are also affected. Thus in chronic alcoholism, we find a tendency to fibrous thickening of the tissues, whether these be in brain, liver, or kidney. We find, again, degenerations of a particular kind in syphilis, and in lardaceous disease, which is sometimes its sequel. From other causes, we may find the whole of the bony skeleton diseased, or the lymphatic glands, or the skin. Thus, as before said, it is but a shortsighted view to see special organs only affected by disease, rather than a general morbid condition affecting particular tissues, and occurring under given determinate circumstances. Such views as these have arisen, I believe, from a closer study of the dead; and this has been so little perceived by some, that I have often had to vindicate this department of science to those who have seen no more in it than a curious prying into the body, in order to discover the destruction of some great organ or satisfy a curious diagnosis. At one time, it is true, a diseased organ was simply cut to pieces, and the rest of the body not examined; but now-a-days, when the process is more searching, I maintain that a much larger view of pathological processes is obtained by a dissection of the dead, than could be arrived at by mere observation at the bedside. The narrower views of the ward are expanded in the dead-house. Much larger conceptions are gained, both as to the nature of the disease and its diagnosis. A simple name for a diseased organ is sufficient for the ward; but the name for a distinct pathological process is required for the dead-house. In a paper published some years ago, in order to vindicate this view, I took several examples in illustration; and I said, if a person acquainted with healthy anatomy were placed in a room to dissect the dead taken from a hospital, he would very soon be able to arrange the cases in classes; he would soon place together, for example, those who had chronic disease of the lungs, those who had died of typhoid fever, and amongst others, those who had that series of changes recognisable under the name of morbus Brightii, even though there might be some slight accidental difference in all of them. There might be, in a series of beds in a ward, one patient dying of pneumonia, another of laryngitis, another of peritonitis, and a fourth of apoplexy; and it is possible under these names the cases might be found in the list of the Registrar-General; but

should they come into the hands of the necroscopist, as an unbiassed dissector he might find a recent inflammation of the lungs in one, or a clot in the brain of another; but since in all he would discover like chronic changes in the kidneys, heart, arteries, and other organs, he would rightly place them together; he would see that they all had the same pathology. This is sufficient to show how all but valueless are the Registrar-General's returns for pathological purposes; for example, if effusion of blood in the brain is to be classed amongst nervous diseases, nothing but error can result in drawing any conclusion of a scientific character from such reports. What I at that time said should be the aim of the pathologist, I repeat now; we should attempt to do for morbid anatomy what Bichat long ago performed for healthy anatomy.

Whilst I am on this subject, I must say a word in reference to another piece of pathology, on which a dissection of the dead can alone throw a light; and one which ere this (I own a personal shame) ought to have been perfected; it is akin to the matter of which we have been just now speaking. If it be true that the morbid changes are found progressing through tissues rather than affecting particular organs, as it were by accident, it follows that these different tissues have their own special morbid changes and none others. What we ask ourselves therefore is this question—what are the morbid changes to which each tissue is liable? Now, it is constantly assumed that degeneration may occur, and new growths of all kinds spring up, spontaneously in every part of the body, but this is certainly not the fact. If we take, for example, the list of diseases framed by the College of Physicians, which is in all your hands, it would seem as if there were certain morbid states, such as inflammation and its consequences, as well as various morbid growths, which may attack in turn every part and tissue of the body. But is this really so? The morbid anatomist ought long ago to have answered the question; and I believe, had my own attention been directed to this subject earlier, the amount of material passing under my hand would have been amply sufficient to have afforded a satisfactory solution to it. I will explain my meaning: supuration of the lung is rightly not regarded as a stage of idiopathic pneumonia; consequently, if an abscess be found in the lung, we know that the seeds of it are brought thither from a distance, and we find the source of the pyæmia in some other part. Cancer again, when found in the lung, has, in my experience, been secondary to cancer elsewhere, and thus we suppose the seeds of it have been there carried; (intra-thoracic cancer may be primary, but generally commences in other tissues than those of the lung); then again, as regards other classes of tumours, as fibroid, myeloid, osteoid, etc., they are invariably found existing there as secondary deposits. Now, if what I say be true, the primary morbid changes in the lungs are strictly limited; the epithelium may produce well-formed cells, as found in pneumonia, and ill-formed ones, as met with in the chronic degenerations, but beyond this the lung may be incapable of alteration. The same with other organs; the kidney undergoes certain limited changes, as seen in nephritis, but these do not terminate in supuration, suppurative inflammation being always secondary; the liver also has certain definite changes, beginning either in the cells or the areolar tissue. The stomach has its own special changes, and is incapable of producing many new formations; as, for example, tubercle. It is thus probably very far from being true that abscess, tubercle, cancer, and other growths occur in all parts and tissues of the body; but, on the other hand, that all these have their favourite or perhaps special seats, and when met with elsewhere must be regarded as secondary formations. It is remarkable how surgeons have always tacitly acknowledged this fact; for, when meeting with a malignant tumour on the surface of the body, they have seldom hesitated to operate from the fear of any internal complication, since their experience has taught them that the growth on the surface has been primary. On the other hand, the teaching of the surgeon with regard to inflammation and its consequences, as occurring on the skin, having been made applicable to the internal organs, has been the cause of a long series of pathological errors. A knowledge, therefore, of the special changes to which each tissue is liable is vastly important; the materials for furnishing us with the knowledge are always at hand, and the possession of it must be near.

(To be continued.)

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, AUGUST 28, 1872.

SMALL-POX AND VACCINATION.

THE report of the committee appointed on the 1st of June last to collate and report upon the returns obtained from the several small-pox hospitals of London, respecting the epidemic through which the metropolis has recently passed, has just reached our hands, and it is a most interesting and incalculably useful document. It enables us, on the faith of nearly 16,000 cases, to form a reliable opinion of the efficacy of the existing methods—prophylactic or remedial—of dealing with the disease. The results, as tabulated by the committee, may be accepted, perhaps, as representing the progress of the epidemic under average circumstances, there being no doubt that the treatment of cases in the metropolitan asylums was far short of perfection, and an equal certainty that these institutions afforded a far greater hope of a favourable issue than treatment in the patient's own home.

The recent epidemic, may, doubtless, rank with the most virulent which has ever occurred in England, and for its violence and the high rate of mortality the mad fools who have busied themselves in discrediting vaccination are certainly more or less to blame.

These fanatics, naturally incapable of a logical view of the subject, and mulishly unwilling to open their eyes or ears, or the desolate temple of their reason, to the teachings of science and of unprejudiced observers, have given currency to a doubt as to the efficiency and expediency of vaccination, and have thus lent themselves to a crusade in favour of this loathsome disease. If anything were to be hoped from the education and persuasion of such persons this report would conclusively dispose of their views.

Rhetoric is wasted on so unfertile a soil, and we must, therefore, trust to the better sense of the people to read

aright the statistics put forth in this report, and from which, as well as from other sources, we proceed to gather a few statistics and the lessons they teach.

The recent London epidemic forcibly illustrates the additional cost imposed upon the ratepayers in consequence of non-vaccination and the imperfect manner in which vaccination is often performed. The average duration of treatment of a well-vaccinated case in one of the district hospitals was about 21 days. Up to the 30th of March last, 14,400 cases were treated, of which 2,700 died, and 11,700 remained under treatment until complete recovery. If all these had been properly vaccinated, the duration of their stay in hospital should have been about 245,400 days, but the actual number of days charged to the parishes and unions for these 11,700 cases has been 378,700, or 133,300 days more than would probably have been the case had all been well vaccinated; which, as the average cost per patient for maintenance has been 1s. 4½d. per day, represents an extra charge of upwards of £9,300 for maintenance alone, exclusive of the proportionate additional expenditure incurred for the salaries and maintenance of officers, and the other establishment charges of the hospitals.

Again, as the average rate of mortality in well-vaccinated cases is only about 4 per cent., the deaths would probably have been under 600 instead of 2,700, and thus 2,100 lives might have been saved.

As to the great question of re-vaccination, it would appear that the necessity of re-vaccination when the protective power of the primary vaccination has to a great extent passed away, cannot be too strongly urged. No greater argument to prove the efficacy of this precaution can be adduced than the fact that out of upwards of 14,800 cases received into the hospitals, only four well authenticated cases were treated in which re-vaccination had been properly performed, and these were light attacks. Further conclusive evidence is afforded by the fact that all the nurses and servants of the hospitals, to the number at one time of upwards of 300, who are hourly brought into the most intimate contact with the disease, who constantly breathe its atmosphere, and than whom none can be more exposed to its contagion, have, with but few exceptions, enjoyed complete immunity from its attacks. These exceptions were cases of nurses or servants whose re-vaccination in the pressure of the epidemic was overlooked, and who speedily took the disease; and one case was that of a nurse, who, having had small-pox previously, was not re-vaccinated, and took the disease a second time.

We now pass on to say a word on the effect of vaccination on the recent epidemic.

The total number of cases of small-pox treated in the London special district hospitals during the entire course of the recent epidemic was 11,174 vaccinated persons and 3,634 unvaccinated. The relative rate of mortality was, for cases which had been vaccinated 10·15 per cent., and for those which had not been so 44·80 per cent., the proportion in both classes being higher in the male than the female sex.

Much has been said by the opponents of vaccination upon the fact that the vaccinated cases received into the hospitals are three times as numerous as the unvaccinated cases; but, for this to be of any importance, it ought, at the same time, to be shown that the number of the vaccinated population is not more than three times the

number of the unvaccinated; so far, however, from this being the case, it is estimated that even previously to the commencement of the present epidemic, the vaccinated were about nineteen times as many as the unvaccinated.

Notes on Current Topics.

Liability of each Sex to Variola.

In the late London epidemic more males than females have been treated (the numbers being 8,053 males and 6,755 females), and the percentage of deaths in the former has been higher than in the latter, in the proportion of 19 males and 17 females. The reasons given by Dr. Grieve for this are the extra wear-and-tear undergone by the man, his more irregular habits (which unfit him to cope with the disease), and his occupation generally bringing him more into contact with the disease. The differences in the numbers and in the death rates of the two sexes arise chiefly in adults. Up to 20 years of age the numbers admitted were 4,112 males and 3,803 females, and the death-rate was nearly the same—17·9 per cent. males, and 17·6 females.

The Reliability of Vaccination Marks as an Evidence of Protection against Small-Pox.

ONE of the tables recently compiled by the Metropolitan Asylums Board from their experience of the recent epidemic shows the decreasing rate of mortality according to the number of vaccination marks, whether good or bad, as exemplified in 5,539 cases. The importance of this table is obvious, for it will be seen that the percentage of deaths which, in the whole of the unvaccinated cases was 55·9, decreased from 15·2 in cases with one mark, to 5·5 in cases with five or more marks. Another table shows the comparative results in unvaccinated cases, in cases which have been badly, and in cases which have been well vaccinated, as taken from 3,085 cases. This table shows that the mortality, which in unvaccinated cases was no less than 47·5 per cent., and in badly vaccinated cases 25 per cent., varied in well-vaccinated cases from 5·3 in those showing one good mark, to 1·1 in those showing four or more good marks; and that of the total of 420 well-vaccinated cases under 15 years of age, the death-rate was only 0·47 per cent., giving a comparative immunity from fatal results.

The Apparent Influence of Age on Small-Pox.

It appears that the proportion of children admitted to the district hospitals in London under 10 years of age was 8·79 per cent. of the whole number of vaccinated cases, and 43·86 per cent. of the whole number of unvaccinated cases;—that between 10 and 30 there were 73·96 per cent. of vaccinated cases, and 42·39 per cent. of unvaccinated cases; and that the percentage of deaths among the vaccinated children under ten was 8·63 of the whole number of deaths, and among the unvaccinated 49·45 per cent. This table also shows that whilst the admissions between the ages of 10 and 20, of vaccinated cases were 40 per cent. of the whole

number admitted, the deaths were 20 per cent. of the whole number of deaths, showing the chances of recovery to be about twice as great as the chances between 20 and 30, when the death-rate was 36 per cent., and the proportion of admissions 36 per cent.

The Duties and Rights of Apothecaries' Assistants.

By a judgment delivered last week at Maldon it was ruled that an apothecary or chemist is bound to provide his apprentice with proper opportunity and leisure for study, book wherewith to learn, and daily personal instruction, and that, failing to do this, he forfeits his apprentice fee. In the case in question it appeared that "in the indenture the defendant obliged himself to use his best endeavours to teach and instruct, or cause to be taught and instructed, the apprentice in the several businesses." The employment had consisted chiefly in mixing up and retailing out seidlitz powders, salts and senna, and other small articles, and in mixing pills, the defendant taking care not to allow his apprentice to know the nature of the drugs and ingredients of the latter, or the purpose for which they were made. No books were provided for the lad's reading; and even if they had been he was allowed no time for the purpose, being engaged in the shop from seven a.m. till ten and eleven p.m. In addition to the above duties he had had to clean the shop, the stoves, shake mats, and perform other menial offices usually executed by a shop-boy. The Judge at once instructed the Jury, if they believed the defendant had not used his best means to instruct the apprentice, to find a verdict against him, which they did, he being mulcted in all costs.

Female Inspector of Poor.

THE Parochial Board of Stromness, in Orkney, having been ordered by the Board of Supervision to annul their election of Miss Corston as inspector of poor, has decided, by a majority of one, to select a male for the office. But now Miss Corston refuses to go out of office, and maintains that the action of the Board is illegal. The ratepayers evidently sympathise with her, for they have just elected a woman to represent them at the Parochial Board.

Removal of a Loose Cartilage from the Knee-joint.

DR. JOHN D. JACKSON (*Cin. Lancet and Observer*) successfully removed, by a subcutaneous incision, a loose cartilage from the right knee-joint of an Irishman, 40 years of age. While searching for the records of cases of extraction of loose cartilages from joints, Dr. Jackson came across a paper communicated to the Society of Surgery of Paris, by M. Larrey, containing statistics relative to the success of the various operations undertaken for the extraction of false cartilages in or about the knee-joint. Out of a total of 170 cases of extraction, 131 were by direct incision, and 39 by the indirect or subcutaneous method.

No. of Cases.	Cured.	Failures.	Deaths.
131	98	5	28
39	19	15	5

According to M. Larrey, this operation should never be performed, unless the following conditions be realized:—

1st. Complete mobility of the false cartilage. 2nd. Presence of pain, effusion in the joint, lameness, and other ill effects resulting from its presence in the articular cavity. 3rd. Failure of palliative means. 4th. Express desire of the patient to undergo an operation, after all its dangers and difficulties have been fully explained.

He has collected, tabulated, and appended thirty cases of removal of loose cartilages from the knee-joint, showing two deaths to the thirty cases, which would scarcely justify Benjamin Bell in his recommendation of amputation, or Velpeau in his conclusion that one-third of those operated upon perished. Analysing further the collection, with reference to the modes of operation, we find that there were two deaths, one amputation, and one ankylosis, to sixteen successes by the direct method of operation, and that there was one ankylosis to ten successes by the method of Goyraud.

Dr. Jackson thinks that a great majority of the Profession much over-estimate the gravity of wounds of this locality. In the case of his patient no excessive reaction followed, and in only every seventh case of others, which he has compiled, did it occur.

Maltreatment of a Lunatic in the Ennis District Asylum.

At an adjourned meeting of the Clare Board of Governors a complaint was investigated against one of the attendants by Dr. Baron, the Resident Medical Superintendent, for grossly maltreating a patient under his charge. The facts disclosed were these. It seems the poor demented creature, who is remarkably quiet, took the hat off another man and put it on himself, and went on fooling about, when the attendant knocked him down, and while on the ground put his knee on his chest, and gave him a black eye. On the whole, the conduct of the attendant was both harsh and cruel, without any palliation or excuse; but in consequence of its being the first complaint against him he was allowed to send in his resignation. The Board shortly afterwards adjourned.

Cerebral Abscess.

SURGEON J. F. WEEDS, U.S. army (*Nashville Journ. of Medicine and Surgery*), publishes a case of cerebral abscess. The patient was a lieutenant who was wounded in the forehead by a ball from a Colt's navy revolver. Feeling satisfied that his patient was dying, and that pressure was produced by a cerebral abscess, he trephined, and incised the dura mater, and plunged the knife into the cerebral substance. Half-an-ounce of dark-green and somewhat fetid pus flowed from the wound. The wound healed rapidly, and in two weeks the patient was walking about convalescent.

Surgeon Weeds says there are 214 recorded cases, including his own, in which there were only four recoveries, and one case the result of which was doubtful.

Dislocation of the Radius and Ulna Backwards in a Young Subject.

Dr. W. T. BRIGGS, Prof. of Surgery in the University of Nashville (*Nashville Journ. of Medicine and Surgery*), records a case of dislocation of the radius and ulna backwards, in a patient two and a half years old. He regards this instance as one worthy of report, as Malgaigne says

that of 643 dislocations only one occurred under five years of age; and Hamilton, in his treatise on "Fractures and Dislocations," states that of 56 cases of dislocations of the radius and ulna, the youngest was five years of age.

Pruritus Vulvæ.

Dr. McGRATH speaks well in the *Canada Lancet* of the following lotion: it should be applied by means of a soft sponge after ablution, morning and evening: R. Biborate of soda, ℥ij.; Hydrochlorate of morphia, gr. xx.; Hydrocyanic acid, ℥j.; Glycerine, ℥j.; Distilled rose water, ℥viij.

Ancient Methods of Delivery.

Dr. WM. GOODELL gives, in a paper in the *Am. Journ. Obstetrics*, with five woodcuts, the histories of some ancient methods of delivery which are not known to the Profession at large. The history is noted from the time when "the King of Egypt spake to the Hebrew midwives," in Exodus i. 15, 16, down to the days of Hippocrates and Albucasis, when tossing up a woman in a blanket was recommended by the latter, in malpositions.

Small-pox in Naas, County Kildare.

The *Leinster Express* announces that small-pox has broken out among the County Dublin Light Infantry, at present stationed in Naas. It is said the regiment will be removed and placed under canvass.

Munificent Gift to the Stewart Asylum.

WE observe with pleasure that the committee of the Stewart Institution for the Education and Maintenance of the Idiotic and Imbecile, situated at Lucan, near Dublin, at their last meeting were informed that a gentleman, a good friend to the institution, has offered to give £1,000 towards the new buildings at Palmerston, on condition that the other £4,000 be raised for the same purpose within twelve months.

Influence of Barometric Pressure on Anæmia.

M. CLAUDE BERNARD presented recently to the Paris Academy of Sciences a note by M. Bert, on the influences which changes in barometric pressure exercise on the phenomena of life.

When the pressure diminishes, the quantity of gas contained in the blood also diminishes. Thus a man who goes up in a balloon, or ascends a mountain, possesses, in the blood at his disposal for the excitation of his tissues and to furnish the waste of his labour and his animal heat, a constantly decreasing quantity of oxygen, which shortly becomes insufficient. A diminution in the proportion of oxygen in the blood becomes evident on a diminution of 20 degrees in the pressure; that is to say, under conditions almost the same as those in which millions of people live, especially on the great plateau of Anahuac, in Mexico. Inhabitants of such a place are placed every day under a condition of insufficient oxygenation which, if the number of their blood globules does not increase for some other reason, ought to evoke symptoms of anæmia. That such is a fact has been shown by M. Jourdanet.

Army and Navy Medical Experience.

It is by tracing diseases as they affect considerable masses of men placed as nearly as possible under the same external circumstances that we gain the surest and most satisfactory evidence in respect to the causes of disease. And hence it is that the experience of those men who are employed in our fleets and in our armies is so valuable.—*Watson's Practice of Physic, Vol. I., p. 79.*

The Life of the Physician as sketched by the Wife of one.

A WORK purporting to be the journal of a lady, the wife of a Medical man, and recently published, has just fallen into our hands, more by accident than anything else. Its whole tenor is religious; trials and crosses are described as so many preparatives for other and better conditions than are usually to be found by persons engaged in the turmoil of life—and particularly professional life. Throughout its pages charity and goodwill to wards all men are expressed, yet this is what, at page 256, is said of Medical men:—"The life of the physician is necessarily one of self-denial, spent as it is among scenes of suffering and sorrow which he is often powerless to alleviate. But there is, besides, the wear and tear of years of poverty; his bills are often disputed, or allowed to run on from year to year unnoticed; he is often dismissed because he cannot put himself in the place of Providence and save life; and a truly grateful, generous patient is almost an unknown rarity."—*From a Tale of Home Life, by the author of the Flower of the Family.*

An Undescribed Form of Congenital Amaurosis.

MESSRS. DAGUENET AND GALESOWSKI have recorded in the *Journal d'Ophthalmologie* of July last, the cases of three brothers and a cousin-german, born of two sisters, and relatively aged 27 and 21 years, who developed almost simultaneously, amaurotic symptoms, without any appreciable cause, except hereditarism. An uncle became amaurotic at 21, and also another cousin-german.

The disease was consecutive atrophy or peri-neuritis. The two eyes were attacked simultaneously, the loss of vision increased, and then stopped without resulting in as complete a degree of blindness as ordinary amaurosis. The difference of development of this disease was that the cephalo-rachidien liquid introduced itself between the structures of the optic nerve at this advanced period of life instead of commencing at birth.

Case of Tetanus.

An interesting case of tetanus is reported in the *Madras Monthly Medical Journal*, treated by Surgeon-Major Paul with large doses of tincture of belladonna. From three to seven drachms of the tincture were given daily in doses of twenty minims, showing the great tolerance of this medicine when given judiciously and under careful superintendence.

The case did well, but in estimating the value of any particular treatment in this disease it will be wise to remember that when tetanic symptoms do not occur during the first week, recoveries are frequent under

ordinary treatment. In this case the symptoms did not occur until the eighteenth or nineteenth day.

Tincture of Gelseminium as a Substitute for Quinine.

DR. ANDERSON, of North Carolina, reports very favourably on the use of tincture of gelseminium as a substitute for quinine. He says he has found it a reliable agent in intermittent, remittent, and typhoid fevers, acute rheumatism, and pneumonia. He prefers it in the treatment of the latter disease to veratrum and digitalis, as it reduces the force and frequency of the circulation with equal certainty, and without the unpleasant effects of those agents. It gives speedy relief to precordial restlessness and irritating cough.

David Wooster, of San Francisco, writes in great praise of the fluid extract of eucalyptus. He says it is a diuretic of rare virtue, and may be given when most other diuretics are inadmissible. It is, he states, an aromatic tonic of notable restorative effects in a low state of the system, typhus, diarrhoea, and dysentery.

In vesical catarrh it cures alone, and relieves spasmodic stricture with great promptness.—*Chicago Medical Examiner.*

THE judge of the Sheffield County Court last week delivered a curious decision. A surgeon in the town had entered about forty complaints, and when the first was called on, the judge asked him whether he was a surgeon or an apothecary, or both. He replied that he was a surgeon only. The judge asked him whether his claim was for surgical operations or for medicine, and the plaintiff replied that it was for medicine. The judge then informed him that, according to the Act of Parliament, he could only sue according to his qualification, and as he was qualified only as a surgeon, he could not sue for medicine, but only for what was done in his profession as a surgeon. The plaintiff thereupon withdrew a number of other claims for medicine only, and where the claim was for both surgical assistance and for medicine he had to abandon the latter part of the claim. Such a decision is obviously bad law. It has been repeatedly ruled that a registered Medical practitioner—whether an apothecary or not—may discharge and recover charges for any functions contemplated by the Act. An apothecary is, as we all know, competent to sue for Medical advice, and the obverse rule is true in regard to a Medical man as regards apothecaries' functions.

THE *Philadelphia Medical Reporter* says that the habit of eating arsenic to beautify the complexion is largely on the increase among both sexes in New York.

IN a case at the Middlesex Sessions it was incidentally stated that in three rooms of a lodging-house kept by a witness for the defendant ninety-two persons slept, thirty-six males and females being accommodated in a single apartment.

DR. HOLMES COOTE administers creasote in minimum doses made into pills for incontinence of urine in children with the happiest effects, even when all other treatment has failed.

CONTRIBUTIONS ON THE THEORY OF ILIO-TYPHUS, FROM THE CLINIQUE OF PROFESSORS SKODA AND OPOLSER.

(Editorially reported in the *Allgemeine Wiener Medizinisch Zeitung*.)

(Translated by THOMAS BODKIN, F.R.C.S.I., for the MEDICAL PRESS AND CIRCULAR.)
(Continued from p. 163.)

FURTHER, experience teaches that in meningitis when exudation has resulted, which may not yet have attained to a decidedly great amount caused by pressure on the brain, the result of hyperæmia, an anomaly in the heart's movement comes to be observed, manifested by a prolongation of the intervals between its beats, in which the pulse is progressively retarded from 140—120 to 60, and even to 40 beats in the minute, the reverse being the case usually observed in typhus, the heart's action increasing in rapidity, and as a consequence the pulse rises to 120—130, and even still higher.

Gradually, however, these symptoms characteristic of meningitis fade away; in the more advanced stage the pulse becomes accelerated, presenting the typhus character of the disease; then comes the vomiting principally associated with meningitis—with ilio-typhus, on the contrary, extremely rare. When the vomiting sets in in the more advanced stage, and, for example, with a clean tongue and with scarce any disturbance of the head, and that not any kind of food but slime and bile is ejected, all this specially indicates meningitis; besides, severe vertigo is present almost always in both the commencement of and through the progress of ilio-typhus—seldom or never in the other disease. Furthermore, it is to be observed that in meningitis the bowels are not paralysed and the abdomen not at all tumid, but even seems to be strongly contracted, whilst in ilio-typhus whenever delirium or stupor sets in the abdomen becomes more or less tympanitic.

The paralysis of the bladder, which is globe-like and distended in meningitis, appears very much earlier in this disease; while, on the contrary, in ilio-typhus as a rule the paralysis of the bladder and of the intestinal canal comes on much later. Meningitis also runs a more rapid course than ilio-typhus, and we have especially in meningitis stiffening of the neck, followed with coma and general paralysis; in ilio-typhus the paralysis of the voluntary muscles, as well as of the organs of sense, comes on but late and slowly, whereas in meningitis the advance is rapid.

In meningitis the expression of the features is manifestly more animated, even with the co-existing presence of unconsciousness, than in ilio-typhus, and shows not the same amount of relaxation as in ilio-typhus, in which before even the patient has become unconscious the countenance earlier exhibits an expression of greater lassitude and weariness. Ilio-typhus has been recognised by physicians from the mere expression of the countenance, and we ourselves remember an interesting case as to the question of a diagnosis in Oppolser's clinical ward, which at one time was taken for meningitis, at another for acute miliary tubercles, and again for ilio-typhus; and as Oppolser diagnosed ilio-typhus at a glance, he observed, in order to acquire the power of diagnosing ilio-typhus at a glance, it will require the careful observation of at least a thousand cases; and here in this case the dissection confirmed the judgment of the honoured and celebrated diagnoser, as there was not found a vestige indicative of either acute miliary tubercles or of meningitis, whereas ilio-typhus in the stage of infiltration was well marked. In reference to sopor, it comes to this, that in ilio-typhus the patient can be sooner awakened than in meningitis, in which latter case it is scarcely possible to bring the patient to his recollection.

A difference also occurs in the character of the delirium. In ilio-typhus it is more vague, in which the patient does not adhere to one idea, but passes from one hallucination to another, while in meningitis it is louder, he adheres to one idea, continually and loudly repeats a word or an entire sentence, which never occurs in ilio-typhus. All these

guiding distinctive marks and stages, all else considered, often afford grounds for a distinction to be made between ilio-typhus and meningitis, yet they may all be very obscurely developed, so that for some time one must rest undecided as to what more conceivable the result may be with such a patient. With young persons and children, in whom affections of the brain are generally more intensely defined, less doubt will remain. Isolated cases will occur in which these distinctions in the first days and at the first glance are not so clear, so that a longer time must be waited for in the progress of the case for observation before a diagnosis can be come to. How long this undistinguished difference between ilio-typhus and meningitis may last, taking all things into consideration, cannot well be determined. Nevertheless it frequently happens that this obscurity in the diagnosis may not have long to be waited for. The symptoms peculiar to ilio-typhus make their appearance later; for instance, the increase in the size of the spleen, the inception of meteorism, the acceleration of the pulse, and the temperature pathognomic of typhus. Having regard to the facts stated, in special cases where these have not run rapidly into the lethal state, a differential diagnosis may always be obtained between ilio-typhus and meningitis.

Now as to what happens differentially between ilio-typhus and encephalitis, it is to be remarked, that in the latter will be observed anaesthesia and partial paralysis, partly of the cerebral nerves, partly of the cerebro-spinal nerves, partly of both together, which not unfrequently extends to both extremities, but which is most generally confined to one side, while at the same time double vision exceptionally occurs. Especially do these symptoms show themselves in a host of affections the result of traumatic injury of the cranium, of caries of the os petrosa (*Felsenbüchse*). These etiological data enable us to make exceptions pretty safely, in given cases from ilio-typhus.

When, on the contrary, no injury of the head or caries of the cranial bones exists, it is improbable that we have to deal with a case of encephalitis, and the presumption arises of the presence of ilio-typhus or some other malady to dispose of. There is an evident tendency in the commencement of encephalitis to run a rapid course, and inflammatory irritation of brain and even of its meninges is present, the frequency of the pulse is increased, or in special cases remarkably slow, the temperature is increased, the head is painful with vertigo, sleep is absent, or is broken with uneasy dreams, the sensibility to slight irritations of the organs of sense is increased, the patient feels himself extremely weak and languid, and shows an early tendency to delirium.

Griesenger supposes that these first stormy commencements, which follow a more or less complete latent state, are exactly pathognomic of encephalitis, or abscess of the brain. In the sequence, as paralysis of the brain proceeds, so follows, as the result, loss of intelligence; these few intimations may, when later the symptoms of ilio-typhus become more pronounced, contribute to the diagnosis.

Furthermore, ilio-typhus is ushered in under the appearance of a vehement bronchitis, with a high degree of febrile excitement, chills, and, in some cases, with strong rigors, and swelling of the bronchial mucous membrane. Now, in a bronchitis it is seldom limited to a mere chill, but throughout its entire course the chill is more or less often repeated, and the subjective fever heat shows throughout not a corresponding degree of increased temperature, so that in milder cases in a few days the true seat of suffering will become apparent.

In aggravated cases, all things considered, it is difficult to assure the diagnosis, when the bronchitis sets in with intensity, when an occasional case occurs which runs a severe course, and seemingly wanting nothing of the character of typhus, and, even as it proceeds, delirium, stupor, convulsions, enlargement of the spleen, occur; when, added to these grave symptoms, diarrhoea incidentally sets in, it leaves the physician still longer in doubt of the real nature of the disease.

The respiration may become embarrassed to such a

degree, showing that the entrance of air into the lungs is obstructed, and that the amount admitted is insufficient for acting normally on the blood, which becomes carbonised, resulting in the appearance of cyanosis, therefore it is that somnolency and stupor so suddenly set in, and accordingly the temperature of the body falls, the feet and hands become cold, while the internal heat even continues to be considerable.

The obstruction of the entrance of air into the lungs will increase the difficulty of breathing, and dyspnoea will be the result. In such cases of vehement bronchitis it often occurs that there is no copious discharge from the nose, no repeated sneezing, nor in the further progress generally, no exclusive marked period to denote the presence of ilio-typhus, so that it frequently happens that from fourteen to twenty days will elapse before the physician can decide on the real nature of the disease; sometimes even such an attack may run its whole course without showing any distinction between ilio-typhus and bronchitis.

Frequently, in the obscure progress of such a case when far advanced in its course, unusual manifestations will occur, for instance, profuse hæmorrhage into the intestinal canal, or peritonitis, the result of perforation of an intestine, may occur in the third week, so that by thus waiting, light may be thrown on the nature of the disease.

However, these late elucidations will not always be very welcome to the physician, but in such exceptional cases the prevalence of the typhus epidemic, perennial or not perennial typhus, the age of the patient, the sensibility in the cæcal region, the dicrotus of the pulse meteorism, as well as epistaxis, may afford a sure stand-point for the diagnosis of ilio-typhus.

EXCISION OF JOINTS ON THE FIELD.

A Lecture delivered before the Surgical Society of Vienna on 29th May, 1872; compiled from the notes of Dr. Carl Fieber.

(Translated from the *Feldartiz* by ASSISTANT-SURGEON MACROBIN, Rifle Brigade.)

THE excision of joints has had during the last ten years more particular interest to the army surgeon than almost any other subject in military surgery. It is worthy of remark in the history of this class of operations that in civil life in cases seemingly incurable it has been practised for about a hundred years, and to a very great extent indeed since the commencement of the present century. In Germany the schools of Würzburg and Erlangen in particular have adopted it, and it is a subject of wonder that the experience gained in another sphere of action was not sooner turned to account in military practice for the treatment of these very serious injuries; for the operation was never at one time practised except in those cases in which the bones forming the joint protruded through the skin were sawn off; thus completing an operation which one may say was already commenced by the destructive missile. To this series may be added a few isolated cases. The results in civil practice had for a long time quite settled any doubts with regard to the success of the operation, and thus made the experiment in military practice by no means a rash one. The extremely bad prognosis of all gunshot injuries of the joints was also a further inducement to render this new mode of treatment justifiable; nevertheless, by the elder surgeons of reputation have only few, such as Larrey and, about the same time, Textor of Würzburg, and Michael Jäger, of Erlangen, undertaken this line of practice as opportunity offered. They stood by themselves and found no imitators for a long time. This state of affairs remained unchanged until towards the middle of this century, when the practice of excision of joints made a rapid stride, viz., in 1848-49, during the first Schleswig-Holstein war. It was Stromeyer and Langenbeck who then first recognised the particular significance of this operation in military surgery. They were doubtless influenced by their visit to Julius Hospital, at Würzburg, where they saw the good results following from the operation. Their experience became the starting point for the

permanent establishment of this important series of operations. The next who further established its success was Pirigoff, who, during the Crimean War, practised it extensively, principally in the joints of upper extremities, in which he himself operated 200 times. During this campaign he also recognised the value of the plaster of Paris bandage; the operation was not, however, extensively practised by the army of the allies. Again, in the Italian war of 1859, the Austrian surgeons took it up. The American war lasting four years brought much new material for its observation and greatly enhanced its value. In future campaigns no further opposition was made, quite the reverse, for in the Schleswig campaign of 1864 and in the German and Italian campaigns of 1866, and, lastly, in the greatest and last of modern campaigns, that of 1870-71, it was universally adopted. The French surgeons only stood aloof, otherwise, all the most distinguished surgeons in Germany, England, America, and Russia, were in favour of it. If we ask ourselves what then is the principle of the operation in injuries of the joints, the answer is so simple. The resection of joints is an operative proceeding, in which, by certain incisions through the soft parts, the cavity of the joint is opened, after which is removed, generally with the saw, one or other of the bones entering into the joint to a greater or less extent, and in many cases a part of the synovial membrane is also extirpated. What particular end does this satisfy? To make this clear, we must first consider the extreme consequences of the joint being left to itself. It is true that wounds of joints, if inflicted by sharp cutting or thrusting instruments, if the bones are uninjured, often quickly get well under ordinary antiphlogistic treatment. There are also other cases which may recover under conservative treatment, viz., in those cases of gunshot wounds without or with insignificant splintering of bone. Let us call these, for sake of distinction, incomplete injuries of the joints, as all three principal constituents of joint, synovial membrane, cartilage, and bone, are not injured at one and same time. These cases, however, of wounds of the joints complicated with fracture of the bones, invariably develop every source of danger if left to themselves from the traumatic inflammation going on rapidly to suppuration. The inflammation of the synovial membrane sets in with remarkable rapidity and with great violence, and before commencement of suppuration the fever reaches an extreme height, the joint at same time swelling to an enormous size. Inflammation having set in suppuration quickly follows, this increases, and pus fills up the cavity of the joint which, being under great tension and in constant contact with the synovial membrane, one of the most absorbent of all the tissues, is taken up into the blood; then follows a further increase of fever, which can pass at any time into that form known as pyæmia. If in the joint there are at same time splinters of bone, so must these, bathed in pus and cut off from nourishment, quickly become necrosed and becoming centres of putridity, a quickly killing septicæmia sets in, and carries off the patient in a few days. To the general consequence of leaving a joint to itself, contrast the operation of resection if performed before the setting in of inflammation. It provides by a wide opening a free exit for the pus should it occur, it lessens by the removal of splinters of bone the danger of unhealthy pus forming, and by the removal of the end of the bones forming the joint and any splinters it reduces the risk of inflammation to the soft parts which are most subject to it; it abolishes as much as possible those deep corners and receptacles in which the pus can stagnate, which exist between the ends of the bones and the synovial membrane, extending as it does a considerable way along the bones. This much cornered and recessed cavity is changed by the operation into one single cavity bounded by even walls. The operation also favours by removal of the cartilages, which would otherwise become disintegrated, the ankylosis of the joint, and lastly, by extirpation of a part of the synovial membrane, it diminishes the risk of pyæmia. These are briefly the principal advantages of resection.

THERAPEUTICS :

An Address delivered at the Annual Meeting of the Norfolk (Massachusetts) District Medical Society, May 8, 1872.

By B. E. COTTING, M.D. HARV.

(From the Boston Medical and Surgical Journal, July 4.)

MY FIRST QUESTION

As a Medical Student,—

ITS SOLUTION A SURE BASIS FOR RATIONAL THERAPEUTICS (a).

(Continued from page 121).

But for going only thus far he was violently assailed at home and abroad. The suggestion of a Chair of Natural History of Diseases seemed particularly obnoxious. An American reviewer, who himself only the year before had laid it down, in italics, as a rule, that "*no active medicine should be used in any case, unless the evidence is clear that it will effect good*," thus strongly expresses his dissent:—"We do not believe that it is right for a physician to forego, in any case, the use of positive medication where it is clearly applicable, merely for the sake of seeing how the disease will proceed under the guidance of Nature alone"—overlooking his fatal proviso "clearly applicable," and evidently forgetting that he had then so recently declared that "there are comparatively few active medicines of real value;" and that "we need what Sydenham termed a Natural History of Diseases."

While Sir John Forbes throughout his volume thus endeavoured to show the necessity of a knowledge of diseases without the interference or influence of medicines, and filled whole pages with the enumeration of the causes of the almost absolute ignorance on this subject, he seemed to give up, as almost hopeless, any expectation of a general effort to remove this ignorance, or to acquire the desired knowledge, in what he justly considered the only sure method; and his American reviewer, apparently shuddering at the announcement of the idea of letting disease go on without medication of some sort, could not bring himself to allow the right even to make use of the only truly scientific test, although, while preparing the review, he wrote to the author of the Address of 1852:—"I have just been re-reading your Address. I am glad to find your views so consonant with mine, and I hope that the subject will continue to be pressed upon the attention of the Profession by different writers, each in his own way, so that the good work of getting rid of over-dosing may go on."

Seldom can there be found better examples than these showing how difficult it is, even for those in authority and most self-relying, to rise above popular tenets, and to overcome the ever-pressing and probably unrecognised influence of what Forbes himself calls the "prejudices of education."

He who trumpets into notice a new agent, be it as lithiferous as chloroform or as inert as cundurango, may reasonably hope to be at once called "one of the lights of the age;" and he who impulsively lauds the virtues of any dangerous method or doubtful expedient may be quite sure of being proclaimed its "apostle;" but he who pleads for a little more caution, asks for a little more proof, points out danger, or exposes inefficiency, is liable to be looked upon with suspicion, or to be held in disfavour.

The suggestions advanced in 1852 had proved no exception to the general rule. Though many journals and notices of the Address applauded its sentiments, not a few good and true men appeared to be troubled lest the confidence of practitioners in remedies should be disturbed—so that when the author was called upon, in 1865, to give the Annual Discourse before our State Society (the "Solemn Oration," as it is sometimes called), an ex-President of this District Society, an esteemed friend, in the kindness of his heart, urged that its doctrines should accord with the prevalent opinions of the Profession (a). This kindly intended advice was received in the same spirit it was proffered, but it aroused

a train of thought which ultimately expanded into the discourse itself.

To the leading object of the Discourse my first question naturally followed as a corollary, and received additional force from the demonstration that preceded it. If diseases are a part of the plan of creation, then there must be a plan or law in each one of them, which should be sought out and understood before any attempt can rationally be made to influence its progress or results.

Seven years only have passed since the publication of the Discourse, and yet in this short time such changes have taken place in the opinions and writings of Medical men, through many influences, that one would hardly presume to read the paper for the first time now, lest it might appear to some to be merely a compilation of common-places pirated from the very journals which in the first instance decried it. A series of quotations might easily be gathered up in illustration; but one, from the *Dublin Quarterly*, 1869, will suffice for an example:—"The law regarding them [epidemics] would seem to be as wide-spread as gravitation itself, and, no doubt of it, the Deity has, for his own purposes, ordained that it should be so; and I believe it will not end till time itself is no more."

An incident in point must be pardoned—one especially gratifying to the author—the recent unanticipated conversion of a life-long friend, who had formerly, very kindly and dispassionately, but rather adversely, criticised the leading doctrines of the Discourse. He has lately recorded his present opinion as follows:—"The doctrine that 'Disease is a part of the plan of Creation,' though at times assailed, has never been invalidated, and, better than any other statement, comprehends and explains the facts appertaining to human ailments."

The great and rapid changes alluded to in Medical opinions must astonish our elder members, who, on finding where the advance has taken them, look back to their point of departure. They remember some of the first movements which opened the campaign; but they little thought then that they should live to see such a revolution—for what young men are now taught for true doctrine was considered scepticism less than forty years ago—the heresy of one generation becoming, as is often the case, the established faith of the next. "When, in 1835, the doctrine of self-limitation was announced," says the author of a Prize Essay on Rational Therapeutics, "it was quite common among men to speak of his Discourse [Dr. Bigelow's] as showing that he was unduly sceptical in relation to the powers of medicine. But at the present time, 1857, these views are those of the Profession generally." Since then, too, there might perhaps be found admirers of Sir John Forbes's doctrine among those who once wished that he had been forced to retire from the Profession years previously, so that such fallacies as his could never have been promulgated; and the author of the Discourse of 1865 now unexpectedly discovers his orthodoxy confirmed by one of last year's orators of the British Medical Association, in a passing allusion to "the modern heresy which forbids us to seek for design in morbid processes!"

Nevertheless, at this late day, in regard to the "succession of processes" which constitutes a disease, the dispersion of the series, its jugulation, eradication, and, in failure of these, its subjugation, by "active" interference, are questions seemingly still open with too many practitioners, and to be incon- testably decided *only after the solution of my first question*. Although the books and reports of cases are continually asserting, or leaving readers to infer, that such things have been done, or could be done if Medical men were only called in season, still results when carefully brought to the test do not show sufficient grounds for such inference. It is noticeable that in the bulletins of the late illness of the Prince of Wales no such intimation appears; the Medical attendants having apparently concerned themselves with what occurred from day to day, without anticipations or predictions. And it is further noticeable that the royal person suffered the same changes as the poorest subject is liable to, which would not have been, had skill or appliances been adequate to anything better. Even to such miserable sequelæ as are almost invariably attributed to neglect of some kind, did the case finally proceed, These, which will sometimes happen to the best cared-for, where alleged causes seem entirely inadequate or wholly want-

(a) *Parvis componere magna*, "I trust you will not cast doubts on the efficacy of medicine," said a distinguished member of our Profession, speaking to me of this Address.—SIR WM. JERRARD, M.D., &c. Address in Medicine before the British Medical Association, July 27th, 1869.

(a) "I prefer to be called a fool for asking the question, rather than to remain in ignorance."—DR. JOHN HOKANS (while a Medical student, 1860) to an upstarting Professor.

ing, raise in this instance a crowd of suggestions which should lead every practitioner to juster views of the limitations of his art.

The proclaimed, and perhaps prevailing, ideas of the treatment of acute rheumatism offer another illustration. The most opposite modes of active medication, general and local, have, from time to time, been announced and advocated, for shortening the disease; or more especially, of late, for preventing serious complications, of which "cardiac affections" seemed to be most feared. But rheumatism is self-limited, and cardiac affections are a part of the disease; and, as such, may be the first in the series, or may even exist without any other portion of the body being involved. Cases of the kind have been reported to this society—one in which the disease was diagnosed from cardiac symptoms one or two days before any appearance in other parts; and one, where the disease was chiefly, if not wholly, confined to the heart, with only the slightest subsequent appearance, if any at all, in the extremities. Both cases recovered; in the second instance, the heart symptoms entirely disappeared a few years later as the patient grew to womanhood.

If my first question had been thought of, and an attempt made, whenever practicable, to answer it, for Asiatic cholera, on and since its appearance nearly half a century ago, the Profession might have established, possibly by this time, some rational course to pursue, instead of being left to rush blindly, as much at a loss as ever, into all sorts of treatment; and we might have been saved the mortification of witnessing a re-education, at the last hour, of one of the most eminent and influential teachers, now recommending a course quite opposite to that which he has taught with "silver-tongued eloquence" for forty years past. If the plan now advocated by him is right, then countless patients have suffered at the hands of his numerous disciples up to this time. He virtually admits that he has hitherto been wrong; but seems not quite sure that the course now pursued is the true one—"its recommendation must, after all," he says, "lie in its comparative success." He does not tell us with what to compare it; an erroneous method of treatment, which had been discarded, would manifestly be an imperfect standard. The test we have suggested would be scouted perhaps by teacher and pupils; yet, think you that his patients would have suffered more, or run greater hazards, in its trial than under a, now avowed, wrong management? "I will not pretend to say," says the teacher, of the cases he himself treated, "that these persons might not have done quite as well if they had been left entirely to themselves." This, certainly, is the only answer that can yet be given; and as, in this formidable disease, we still find no settled principles of treatment, a thorough knowledge of its Natural History would be as great a gain to future victims as to the Profession.

How humiliating, also, the last public announcement, if true, of the last American collection of professional formulæ, said to contain all the most recent remedies of the most distinguished living American and European physicians and surgeons, that "these are in marked contrast with the obsolete and hackneyed formulæ to be found in the formularies now in the market." If such a wonderful contrast has been wrought so recently in the prescriptions of the eminent living practitioners, to what can it be attributed; for previous prescriptions were but yesterday considered of equal value and efficacy, though now termed obsolete and hackneyed? What evidence have we that the newly vaunted are better than the recently discarded formulæ? To what standard or test can such a question be brought in hope of a satisfactory solution? Is it unreasonable to require something real by which to fix that standard, when it can also be said of the last grand "System of Medicine" (Reynold's) that "it contains none of the absurdities of works of twenty years ago," although it was then thought that the works and cyclopedias of that time were so nearly perfect that, while possibly something might be added, there would never be need of much alteration or amendment?

All such pitiable oscillating from one extreme to another, with a current gratulation of superior success in each, till a prominent teacher is led to declare, in his lately published Lumlean Course, that "there are few conclusions more striking than the general one of the uncertainty of the art"—all this might have been prevented had the lesser risk been run of ascertaining, for a standard of comparison, what disease would of itself do, before interfering attempts were made to modify it by perturbative agents, whose real influence for good or for evil cannot be irrefragably proved without such a standard.

This is said in no spirit of "Nature Worship" so freely denounced by writers, nor in "dismal want of appreciation

of the true scope of Medical Art and Science"—but in the interests of both Nature and Art. We would hail with delight any "remedy," though discovered by a never so "audacious experiment," if fully proved to be beneficial to the sick—nor ask for the why and the wherefore, believing the reply of Molière's student, *quia est in eo*, to be the most philosophical attainable. But, awaiting this proof, we would have the true physician sometimes at least "a spectator" (until he understood the natural succession of the processes he desired "to meddle with," so far as possible, with their inherent tendency to good or evil results), in order that—and for that solely—he might *know*, not guess, whether "a disease is best let alone or treated by rest and diet," or "whether he can shorten its duration or abridge its sufferings" by any means within reach. This is what we would have him at times "a spectator" for, and it seems strange that, among a class of thinking men in this so-called enlightened age, any should still be found so fettered by the "prejudices of education" as to oppose unconditionally all such observations, since, "in proportion as the judgment is most cultivated there is the least yielding to the 'must-do-something' impulse," (a) and the more especially while the present state of therapeutics continues to be confessedly unsatisfactory, or, as a writer in the *Practitioner* of only last year has it, "undeniably one of chaotic confusion."

(To be continued.)

Gleanings.

Chloralum and Preparations of Chloralum as Disinfectants.

By PROF. A. FLECK, of Dresden.

(Translated for "THE MEDICAL PRESS AND CIRCULAR" from the *Industrie Zeitung*.)

THE Central Chemical Institution, established last year in Dresden for the protection of the public health, of which Prof. Fleck is the director, received, amongst other things, the disinfectants introduced by the Chloralum Company in London, in order that a thorough investigation of the composition and real value of these products might be made. The ostentation with which the Chloralum Company commenced, and still carries on, its operations, points either to the especial excellence of the disinfectants recommended, or to a great mistake. The suspicion against the Chloralum Company in this last respect was augmented by many external appearances which accompanied the undertaking. Those newspapers and journals of Germany which enjoy the greatest circulation have become the debating forum of the Chloralum Company, so that it seems to be high time that an impartial judge, such as the Central Chemical Institution, founded, as it is, under the auspices of the State, should pronounce unreserved judgment on the Chloralum Industry and its products.

The Chloralum Company recommends—1. Chloralum as the safest disinfectant, as free from smell, and not poisonous; and as adapted for the disinfection of urinals and drains, stables, slaughterhouses, street kennels, and horse dung, for internal and external use in affections of the throat, diphtheria, scarlet fever, small-pox, &c.

As Prof. Fleck states in the 2d, 1871, No. 4, the liquid contents of a clean labelled vessel weighing 637.6, half a litre in volume, and 15 sgr. (1s. 6d.) in price, were used for the chemical investigation. This fluid contains:—

82.32	per cent.	water.
0.15	"	chloride of lead.
0.10	"	" copper.
13.90	"	" aluminium.
0.42	"	" iron.
3.11	"	" calcium with gypsum.

100.00

2. Chloralum powder is recommended as an absorbent of organic impurities, as an antiseptic and astringent when combined with wheaten flour, and as a disinfectant for railway carriages, ships, privies, stables, drains, &c.

A tin canister, also very handsomely labelled, containing a white powder of 370 gr. in weight, and 5 sgr. (6d.) in price, was taken to experiment upon. It contained—

(a) Herbert Spencer. The Study of Sociology.

0.72	per cent.	chloride of arsenic.
0.55	"	lead.
0.37	"	copper.
52.43	"	aluminium.
1.55	"	iron.
11.51	"	calcium.
0.72	"	gypsum.
32.15	"	alumina and silicious earth.

100.00

3. Chloralum wool and wadding recommended as a styptic and antiseptic for fresh or suppurating wounds and cancerous tumours, also as a disinfectant for coffins and corpses. A neatly labelled bag, of waterproof material, containing 352 gr. of dried wadding, which had been soaked in 173 g. solid chloralum, or 9.80 g. fluid chloralum, price 20 sgr. (2s.) was taken for experimenting upon.

These analytical results leave no doubt as to the nature and the mode of making the preparations of chloralum, and as to their real value.

The manufacture is as follows:—An alumina containing lime (limy clay) and a small proportion of iron is steeped in ordinary strong muriatic acid, and dissolved as far as possible. The concentrated fluid, cleared from the alumina that remains undissolved, is drawn off, and sold in bottles as *Chloralum* (the name is to be ascribed to its containing chloride of aluminium). The sediment remaining is evaporated, together with the fluid remaining in it, and then dried; this yields the *Chloralum powder*. Cotton or wadding is dipped into the chloralum itself, saturated with it, pressed out, dried, and becomes *Chloralum wool and wadding*.

The arsenic, lead, and copper contained in the preparations are to be ascribed to the impurity of the solvent employed, muriatic acid, and to the apparatus in which the alumina is dissolved.

The real value of the contents of a bottle of chloralum, which is sold at 15 sgr. (1s. 6d.), is not to be computed as above 2 sgr. (rather more than two pence). The value of the chloralum powder, which is sold in tin canisters at 5 sgr. (6d.), cannot be placed higher than 1 sgr. (rather more than one penny), seeing that it is but dried sediment. The chloralum wadding, which is sold for 20 sgr. (2s.) is only worth $\frac{1}{4}$ sgr. (rather more than a half-penny), at the utmost. A solution of 10 g. of sulphate of alumina in 1 lb. of spring water would be a perfect substitute for the above preparations, all the component parts of which, excepting the chloride of aluminium, are to be regarded as impurities or poisons, and this solution would not exceed 1 sgr. in value (rather more than one penny).

To test the value of chloralum as a disinfectant similar quantities of sewage were treated with chloride of lime, alum, green vitriol, chloralum, quicklime and chloride of magnesium, and the clarified solution was tested for its contents of organic impurities (putridity), by means of an alkaline solution of silver. The effective value of this disinfectant and purifier may be gathered from the following figures:—

Chloride of lime.	Disinfectant.	100.0	per ct.	organic matter
Quicklime.	"	84.6	"	"
Alum.	"	80.4	"	"
Green vitriol.	"	76.7	"	"
Chloralum.	"	74.0	"	"
Chloride of magnesium.	"	57.4	"	"

Thus the disinfecting and purifying powers of chloralum stand below those of alum, or sulphate of alumina and copperas (protosulphate of iron), which further recommend themselves by their much greater cheapness.

To sum up the argument concerning the value and composition of the preparation of chloralum: 1. The preparations of chloralum have nothing in common with the similarly sounding chloral hydrate, and are, in point of fact, mixtures of chloride of aluminium. 2. The preparations of chloralum contain chlorine combinations of lead, copper, and arsenic, which renders their employment not free from danger, and which would render their employment as a medicine or as an astringent for open or suppurating wounds dangerous. 3. The price of the preparations of chloralum bears no relation to their nature of their effect. Considering that the liquid chloralum yields a clear profit of at least 700 per cent., and the wadding 400 per cent., the limits of honest trading may be considered as overstepped. 4. The result of these experiments is that chloralum, and the preparations made from the same, must be classed amongst the worthless arcana, and, in

the interest of the public health, as well as in the material interests of the public, a most decided warning must be given against the purchase of the same.

Trephining over a Lateral Sinus.

Professor PAUL F. EVE reports in the *Richmond and Louisville Medical Journal* of May, the following case of this nature:—A stout and healthy man, of forty-two years, was struck two years and ten months ago with a bludgeon, and suffered a fracture of the skull which rendered him insensible for sixteen hours. The depression was at a point midway between the occipital protuberance and the right external auditory meatus, and was about three quarters of an inch in depth, and of the circumference of a silver half dollar. No symptoms of epilepsy followed, but at the date of the operation (October 28th ultimo), the patient was habitually costive, walked with difficulty, and only for short distances; complained of constant weight and oppression in his head, and of a dull, annoying pain, radiating at irregular intervals from the point of the injury; had lost his energy, was never cheerful, and was losing flesh and strength. Nothing could provoke a smile. He was almost without hope, and said that he occasionally felt like losing his senses. At the date above mentioned, a crucial incision being made over the depressed portion of the skull, the insertion of the trapezius and the occipital portion of the occipito-frontalis was raised, thus getting below the superior curved line of the os occipitis; a half-inch Galt's trephine was applied and a button of bone removed without injury to the dura mater. Three discs of bone were thus removed from over the right lateral sinus, which was readily recognised by the deep colour of its venous blood; the angles left by the instrument were trimmed and the flaps replaced, and secured with silver wire. About five ounces of blood were lost and only one artery ligated. The patient expressed himself as feeling better as soon as he recovered from the effects of the ether. Most rigid after-treatment was pursued. A slight reaction on the following day was checked with sulphate of magnesia, and he subsequently experienced not a serious symptom. The wound was kept open for a month by the daily introduction of a blunt probe. The skull, in this case, was found to be unusually thin.

NOTICES TO CORRESPONDENTS.

THE Editor of the IRISH MEDICAL DIRECTORY will be glad to receive, and, if possible, to carry into effect in the forthcoming issue of the DIRECTORY, any suggestions for new matter, or emendations in the old. The Editor will add to the DIRECTORY any information which may appear to be interesting or useful to even a small section of the Profession in Ireland; and he solicits from the readers of the DIRECTORY their advice on the subject.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this request.

All communications intended for insertion, must bear the name and address of the writer; not necessarily for publication, but as a voucher of good faith.

Rejected MS. will always be returned, if a request be received from the author, within one week after the article or letter has been declined.

SUBSCRIPTIONS IN THE UNITED STATES.—A Correspondent has drawn our attention to the fact, that some of the houses in the United States are charging the enormous figure of 15 dollars per annum (more than £3) for supplying this Journal to different parts of the States. We beg, therefore, to state that we shall be happy to supply the same regularly post free per annum, if paid in advance, for considerably less than half the amount, viz., six and-a-half dollars (about £1 6s. 0d.), either direct from our offices in this country, or through our recognised agents in the United States.

TO OUR SUBSCRIBERS.—It having been suggested to us that it would be a matter of great convenience to Subscribers visiting the metropolis to know where they can give instructions for their letters to be addressed previous to leaving home, we have pleasure in informing them that the Publisher has consented to take charge of letters addressed to his care, and that he will place a desk at the disposal of Subscribers whose names are upon our lists, for short correspondence, where such accommodation is desired.

THE FOOD REPORTS.—The next Series of Chemical and Physiological articles upon the important subject of Food, will be devoted to Meat Extracts, Australian and other imported Preserved Meats. We trust this Series will be as useful to our readers in determining the relative

value of food substances, and provoke as much interest generally as those which have already appeared. We shall be fully prepared to give the results of our investigations in the course of two or three weeks.

S. L. E.—1. Probably it is not illegal. It might be argued he who does by another does himself. 2. The question might be raised, but it would be said that the custom is to act by deputy, and we think that such a custom is very prevalent. 3. We do not suppose, even if the two former questions were determined against the party, that there would be any chance of such action as you mention.

We venture to commend to the notice of a few members of the Profession, who are at least our readers, if not our supporters, the following emphatic protest contained in the last issue of the *Canada Lancet*.

Speaking of the efforts of the publishers to extend its circulation in Canada, the *Lancet* says:—

"There are always some of course who do not wish to subscribe, some who are taking as many journals already as they have time to read, some who cannot afford a luxury of this kind, while there are others who do not subscribe to any journal, who do not read any new Medical works or journals, and do not wish to, who have still a plethora of knowledge on hand since their school-boy days, and do not require any new ideas; others who look upon the paltry amount of the subscription as more than they care to pay for anything of the sort, who look upon the Profession solely as a means of making money, and console themselves by saying, 'We have got along very well before journals were published, and we can do so still.' We take this opportunity of referring to the unkind treatment we have received from some Medical men who lay claim to respectability. These gentlemen are in the habit of taking the journal from the post office regularly, some of them for upwards of a year, and when the bill is presented they either repudiate it entirely, or invent some plausible excuse for not contributing their quota of the expense of publication. We care little for the loss thus sustained, but we regret to find such men in the Profession, and in one or two instances we felt disposed to give their names the benefit of a public announcement. Such conduct is not in keeping with the dignity of the Profession, and we believe it would have a salutary effect to hold such men forth in their true colours."

Mutato nomine de nobis fabula narratur. We are compelled to make the humiliating admission, that the gratuitous patrons of Medical literature are not a special growth of the Canadian soil. We were last week favoured with a communication from such a one, who naively informed us, after the receipt by him of sixty-four consecutive numbers of our journal, that he thought it was sent to him for the year and quarter by 'some lecturer or other.' Not to talk of honour and justice to such persons, we content ourselves with the remark that it is an indisputable principle of the law, that a person who week after week receives and makes use of goods of any sort—even if such goods are sent in error—and takes no means to put a stop to the sending of them, is liable to pay for them; and if a newspaper publisher refrains from enforcing his claim, it is not because there is any doubt of his right to recover, but because the people who adopt this line of conduct are not usually worth the trouble and expense of law proceedings.

To the Editor of the "Medical Press and Circular."

SIR,—I take the liberty of requesting that the "Student's Column" in your paper may, if possible, appear every week.—Your obedient servant,
A SUBSCRIBER.

[The communications to which our correspondent refers are finished; but we shall endeavour to follow up the series by similar contributions on other subjects.—Ed. M. P.]

FR. BARTHOLOMEW'S MAN.—It shall receive attention.

Several letters, communications, and other articles, already in type, are unavoidably postponed. Some answers to our correspondents must also wait.

VACANCIES.

- Basingstoke Union. Medical Officer for the Basingstoke or No. 1 District. £85 per annum. Fees extra.
- Bridgwater Union, Somersetshire. Medical Officer for the North Petherton or No. 9 District. £84 per annum.
- Brighton and Hove Dispensary. Resident House-Surgeon. £100 per annum, furnished apartments, coal, gas, and attendance.
- Castlecounell and Annacooty, co Limerick. Medical Attendant to the Royal Irish Constabulary.
- Charing Cross Hospital. Assistant-Surgeon.
- Cloghan, co Donegal. Medical Attendant to the Royal Irish Constabulary.
- Gloucester County Lunatic Asylum, near Gloucester. Junior Assistant Medical Officer. £80 per annum and board.
- Huddersfield Infirmary. Assistant House-Surgeon. £40 per annum, and board and residence.
- Limerick Union, co Limerick. Medical Officer, etc., for the Annacooty Dispensary District. £100 per annum. Fees extra.
- Liskeard Union, Cornwall. Medical Officer and Public Vaccinator for the Callington District. £65 per annum. Fees extra.
- Martley Union, Worcestershire. Medical Officer for the Leigh or No. 4 District. £85 per annum.
- Middlesex Hospital Medical College. Two Entrance Scholarships. £25 and £20 per annum, for two years.
- Royal Free Hospital, Gray's Inn Road. Resident Medical Officer.
- St. Mary's Hospital Medical School. Scholarship: £40 per annum for three years. Exhibition: £20 for one year.
- St. Marylebone, Parish of. Medical Officer for the St. Mary District.
- Sculcoates Union, Yorkshire. Medical Officer for the Sutton District. £80 per annum.
- Stranorlar Union, co Donegal. Medical Officer for the Cloghan Dispensary District. £100 per annum. Fees extra.
- Sussex County Hospital. House-Surgeon. £80 a year, with £10 a ear from each resident pupil, board, and residence.

- Uttoxeter Union, Staffordshire. Medical Officer for the Rocester District. £32 per annum, and extra fees.
- Warneford Lunatic Asylum, Oxford. Resident Medical Superintendent. £260 per annum, with board, &c.
- Waterford District Lunatic Asylum. Resident Physician Superintendent.
- West London District School, Ashford, near Staines. Medical Officer. £120 per annum.

- WINSTANLEY.—On the 17th of August, E. Winstanley, M.R.C.S.E., late of Wigan, aged 39.

The Medical Press and Circular

OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements, from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c. it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales and Transfers of Practices, Surgical Instruments, Chemicals, and Trades generally.

The scale of charges is as follows:—

Seven lines and under	£0 4 0
Per line afterwards	0 0 6
One quarter page	1 5 0
Half-page	2 10 0
One do.	5 0 0

When advertisements are given for a series of insertions, a very considerable reduction from the above scale is made.

Advertisements for Insertion in this Journal must be at the OFFICE, on SATURDAY, by Two o'Clock.

The Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

EYE DISEASES AND INJURIES.

A Course of Lectures.

By ARCHIBALD HAMILTON JACOB, M.D., DUB. UNIV., F.R.C.S.I.,

Chief-Surgeon to the Dublin Infirmary for Diseases of the Eye and Ear; and Ex-Ophthalmic Surgeon to the City of Dublin Hospital.

My last lecture (MEDICAL PRESS AND CIRCULAR, May 1, 1872) entered into the consideration of penetrating wounds of the orbit, not, however, involving any injury to the eye itself.

Dislocation of the Eye-ball. It is possible, however, that an actual dislocation of the globe of the eye may take place as the result of a blow with the knuckle, or with a blunt instrument, having a sufficient force to displace the eye without penetrating the orbit, or causing a wound.

This displacement of the entire eyeball, which is illustrated in the accompanying figure, copied from Mr. Haynes Walton's valuable treatise, is very rare, and arises when the eye is forced forwards until its equator passes beyond the palpebral opening, and when the orbicularis muscle and elastic structures close in behind it. Dr. Jameson, of Dublin, communicated in 1853 such a case to the Surgical Society of Ireland. A powerful man, while staggering about in his room drunk, struck his eye against a small iron hook or nail, which entered at the outer angle of the upper eyelid, and protruded the eyeball, rendering it firmly fixed, staring, and devoid of vision. When examined two hours afterwards the cornea was dry, cloudy, and rather opaque, and the pupil, moderately contracted, was uninfluenced by the light of a candle. Blood was not extravasated, nor was there any unnatural vascularity of the conjunctiva, although its upper sinus was torn partially through. I have myself seen the accident occur in the attempt to examine the posterior

part of the eye when it was permanently extruded by a tumour. The tension of the optic nerve usually renders the eye for the time totally blind, but on its replacement vision is immediately restored.

A case, which illustrates the temporary blindness arising from tension of the optic nerve is related by Mr. Benjamin Bell. The eye was almost completely turned out of its socket, by a sharp-pointed piece of iron pushed in beneath it. The iron passed through a portion of the orbit, and remained firmly fixed for the space of a quarter of an hour, during which period the patient suffered exquisite pain. He saw none with the dislocated eye; and the protrusion being so great as to lead to the suspicion that the optic nerve was ruptured, Mr. Bell doubted whether it would answer any purpose to replace it. He found, however, on removing the wedge of iron, which, being driven to the head, was done with difficulty, that the power of vision instantly returned, even before the eye was replaced. The eye was now easily reduced to its

original situation; inflammation was guarded against, and the patient enjoyed perfect vision.

The reduction of a dislocated eye is effected by insinuating the thumb nail of one hand, or, if that be impossible, a curette, under the upper lid, and pressing the eye back by the other thumb placed against the cornea; but if this manœuvre should fail the outer canthus must be divided.

Orbital Abscess. The occurrence of an abscess within the walls of the orbit may be either acute or chronic. The acute form is always the result of orbital cellulitis, or inflammation of the cellular bed on which the eyeball lies, and it is, therefore, attended with very serious inflammatory symptoms and very active symptomatic fever. Its causes are fourfold—*viz.*, 1. Wounds with or without impaction of foreign bodies. 2. Exposure to sudden changes of cold and heat. 3. Metastasis or the deposit of pus in cases of pyemia, phlebitis, erysipelas, &c. 4. Periosteal inflammation.

Mackenzie says that erysipelatous inflammation, spreading from the eyelids to the cellular membrane of the orbit, sometimes terminates in abscess within that cavity, or effusion of matter within the orbital capsule. This appears to be one of the modes, perhaps the most frequent but least suspected mode, in which erysipelas of the face or scalp proves fatal. The fatal result, under such circumstances, is generally ascribed to effusion within the head, but may happen without any inflammatory affection of the membranes or substance of the brain being detected after death. In such cases the formation of matter within the orbit sometimes takes place suddenly, at other times slowly and insidiously.

Stellwag Von Carion remarks that also orbital abscess occurs not unfrequently in the course of purulent meningitis, from the inflammation passing through the orbital fissures to the loose connective tissue of the orbit, and in such case usually occurs on both sides; and Fischer further observes that it may arise from a local deposit of tubercle.

Symptoms.—Though the formation of an orbital abscess by violence is generally immediate, sometimes an interval of several days may elapse between the injury (if the abscess be traumatic) and the result. The onset commences, especially in the metastatic form, with a rigor. The eyelids become red and distended with serum, and pain in the brow sets in with gradually increasing severity, and generally in paroxysms. When the orbital inflammation is deeply seated and not very intense the swelling of the lids and conjunctiva frequently bears the character of pure œdema. When it is intense or superficial, however, it often appears erysipelatous and is hot, tense, and deep red. In a day or two the eyeball will appear protruded, not always directly forward, but its upward or downward direction will afford an indication of the position of the abscess.

Cellulitis in the advanced stages, may be mistaken for panophthalmitis, but the protrusion of the eyeball will at once indicate the orbital infiltration. It may also be confounded with periostitis of the orbit, but this condition can readily be diagnosed by pressure. If pressure on the eyeball itself produce severe, deep-seated pain, there is no doubt of cellular inflammation; if not, and if pressure on the margin of the orbit indicates tenderness, the periosteal inflammation will be recognised.

The diagnosis of an abscess in the early stage before marked displacement of the globe takes place, or in case the purulent depot be situated directly in the axis of the orbit, is by no means easy. The chemosis and lividity of the lids and conjunctiva, and the violent paroxysmal pain are likely to confound the disease with one of violent ophthalmitis. If the case be one of abscess, the conjunctiva is rather œdematous than vascular, and the symptoms of corneal and iritic inflammation, which are always present when deep-seated inflammation of the eyeball exists, will not be developed.

At first the protrusion of the globe may be insignificant, and unless by careful comparison side by side with the other eye may be overlooked, but afterwards it becomes marked and sometimes goes to the extent of dislocating the eyeball. If the protrusion be to one side the position of the cellulitis or of the consequent abscess will be indicated, but if the direction of the eye be forward, the pus is probably deep behind the eyeball. Concurrently with this protrusion the sight is impaired by the tension of the optic nerve, till at last it is, for the time being, totally lost.

The displacement of the eye is very accurately illustrated in the accompanying drawing, which I have copied from Mr. Walton's book.

The pain of a simple orbital abscess is usually dull and deep seated, and only becomes violent when the extrusion of the eye is extreme.

Treatment.—In a few cases, especially of the more chronic form of abscess, absorption of pus and resolution may take place, but in the great majority of instances, the abscess will point, usually forcing the conjunctiva of the palpebral sinus out before it before discharging itself. If the case appear likely to take this course, it will be well to encourage it by poultices and mild saline cathartics.

If the patient has suffered violence the possibility of impaction of a perforating body must be remembered even if the external injury be apparently very slight, and search should be made for an external opening, be it ever so small.

If the abscess be caused by the entry of a foreign body, there is a direct exit for the purulent matter, and the source of irritation being removed, it will end in resolution, like an abscess elsewhere.

But it may come spontaneously, or from a blow followed by extravasation of blood, but without puncture; and in this case, of course, considering the danger of its pressing backwards towards the brain, or causing necrosis of the orbit, an incision for its exit should be made at an early stage, exploration having been previously made, if there be any doubt of the existence of pus, with the grooved needle.

This course becomes necessary also when the eye is in serious danger, either from the pressure or from being extruded outside the natural covering of the lids.

If the pus should not be evacuated it will probably find its way slowly, and with great suffering, and present forward at the base of the chemosed lid, or perhaps under the conjunctiva. When the pus is discharged the eyeball partly resumes its natural position, but frequently

the puckering of the muscles in the orbital cicatrix produces a partial strabismus.

As soon as, by careful examination, fluctuation can be detected, or before it, if the protrusion be great or cerebral symptoms threaten, an incision should be made. In acute abscess this must generally be effected through the lid, but if the swelling be inconsiderable the palpebral sinus is, of course, a more desirable locality.

A previous exploration with the grooved needle should be made in any doubtful case in order that the depth to which it may be necessary to go with an incision, and the exact situation of the abscess may be determined before large openings in so delicate a situation are ventured on. If the pus be located deep behind the globe, the lower palpebral sinus will be the proper place for an incision, as it is easier to reach, and allows the lowest channel for the exit of the pus. The threatening of cerebral symptoms, or of destruction of the eye will be the signal for immediate evacuation of the pus, and the general instruction will be to allow its escape at as early a period as possible. If the wound be external, a large soft poultice should be applied, and the wound kept from healing by the occasional use of a probe. If necrosis be suspected, search should be made for a denuded sequestrum, and it should be removed by a long forceps, such as that employed for removing foreign bodies from the ear. If the suppuration be profuse or continued, support for the system will be demanded, and must be maintained by means of beef-tea and wine, while the constitutional irritation must be kept down by cooling drinks, saline purgative and perfect rest. If the cellulitis be developed, and before any deposit of pus, a few leeches to the temple (or if erysipelas be feared), to the mastoid process will be useful in alleviating pain, and occasionally in averting suppuration.

(To be continued.)

ENLARGEMENT OF THE UTERUS CONSIDERED SPECIALLY WITH REFERENCE TO DIAGNOSIS.

A Clinical Lecture,

DELIVERED AT

THE ADELAIDE HOSPITAL, DUBLIN.

By LOMBE ATTHILL, M.D.,

Fellow and Examiner in Midwifery, College of Physicians, and Obstetric Physician to the Hospital.

You must have noticed the extreme frequency with which I use the uterine sound. Indeed, I may say, that I invariably use it in the examination of all cases presenting symptoms of uterine disease, unless its introduction be contra-indicated by the existence of some special cause. My reason for doing so is this, that in a very large proportion of such cases I find the uterus to be enlarged and elongated. The sound enables me to ascertain whether this be the case or not; should it be so, it immediately becomes my duty to endeavour to decide as to the cause on which that abnormal condition depends. I think, therefore, by directing your attention to some of the causes producing enlargements of the uterus, I shall aid you considerably in forming a correct diagnosis, in many cases of uterine disease; for while the subject of flexions of the uterus has of late years been investigated with great care, and has attracted quite as much attention as it deserves, the condition I am referring to, though intimately connected with, often indeed the cause of, these flexions, has been comparatively little noticed.

It is not surprising that the older writers should have overlooked this condition, for it is only of recent years that we

possess the means of investigating them, and of ascertaining, with any approach to accuracy, whether, in a given case, the uterus was of its normal size and shape, or enlarged and elongated. Now, however, matters are completely altered; by means of the uterine sound we can, in the great majority of instances, decide with certainty the depth of the cavity of the uterus, and, at the same time, the bi-manual method of examining enables us to satisfy ourselves whether or not the uterine walls are thickened and hypertrophied. Some practitioners still hesitate to have recourse to the uterine sound, but, after several years' experience, during which time I have employed it constantly, I am satisfied that it is not only one most useful, but also one of the safest of instruments.

Enlargements of the womb are met with in a very large percentage of those cases in which the symptoms are referable to the female organs of generation. Nor is this a matter of surprise when we remember the changes the uterus undergoes. In the virgin state but a couple of inches in length and an ounce or so in weight, it becomes, under the influence of pregnancy, developed into a large organ capable of containing the full-grown fetus, and weighing several pounds; consequently any circumstance which retards or prevents the return of the uterus to its normal size after delivery, may produce, as is now well known, a condition which often results in permanent enlargement, a condition to which, as I have already explained, the term "subinvolution" is applied. But, in addition to these great changes, the result of pregnancy, the uterus every month, as each catamenial period comes round, increases in weight and, probably, somewhat in size; if, from any accident or imprudence, the natural flow is then checked, that temporary increase may become permanent, an accident which, I am satisfied, is far from being of unfrequent occurrence. Here, then, at the outset, are two palpable causes of enlargement of the uterus.

But we meet with cases of enlargement of the uterus which cannot be referred to either of these classes. Women who have never been pregnant, and never have had any derangement of, or departure from, healthy menstruation, and women who, having conceived, have subsequently enjoyed uninterrupted good health for years, during which pregnancy undoubtedly did not take place, nor yet any derangement of menstruation occur, occasionally begin to suffer from symptoms referable to the uterus, and, on examination, these are found to be due to enlargement of that organ. In such cases I believe this condition may depend on inflammation of the substance of the uterus, either of an acute or chronic character; on simple hypertrophy of the muscular and areolar tissue of the uterus; on fibrous tumours developed in the walls of the uterus; and also, as all are aware, on the existence of intra-uterine tumours of any kind, whether they be polypi, fibrous or cancerous tumours. But, it is not my intention to enter at all on the subject of either uterine polypi or uterine tumours, except with reference to the question of diagnosis. I also purposely omit all reference to the actual existence of pregnancy, or to the retention of any of the products of conception in the uterus, as being foreign to the subject to which I wish especially to direct attention.

To recapitulate, we meet with enlargement of the uterus as the result of—

- 1st. Subinvolution of the uterus after labour or abortion.
- 2nd. Congestion of the uterus from suppression or retardation of menstruation.
- 3rd. Acute inflammation of the uterus, or possibly of its peritoneal covering.
- 4th. Chronic inflammation of the uterus.
- 5th. Hypertrophy of the uterus.
- 6th. The stimulus given to the uterus by the development in its walls of fibrous tumours.
- 7th. The existence of intra-uterine tumours.

1. Subinvolution of the uterus is now a well-known cause of uterine enlargement. There is no doubt but it is most likely to occur in those cases in which any form of inflammatory attack, whether it be peritonitis, metritis, or cellulitis, takes place subsequent to delivery. This fact has been pointed out by several writers. If, then, a patient has suffered from any such attack, the possible effect of it in retarding the normal reduction in the size of the uterus, which should take place within a few weeks subsequent to delivery, must be borne in mind, and we should, in such cases, carefully watch for any symptom indicating the presence of this condition. As a nearly invariable rule, profuse menstruation is the first and most prominent symptom indicating the existence of enlargement of the uterus depending on subinvolution; a symptom capable of being easily explained, when we bear in mind the fact, that not only is there under such circumstances an undue amount of blood contained in the enlarged uterine veins, but also, that the relaxed condition of the muscular tissue of the uterus favours the exudation of blood. This profuse menstruation does not always occur immediately; sometimes a month or two first elapses; but, ere long, menorrhagia shows itself, frequently of so violent a character as to assume the proportions of hæmorrhage, and, on instituting an examination, the sound reveals the true state of the case by proving that the uterus is abnormally elongated. The depth of the uterine cavity varies greatly in such cases. I have met with one instance in which it measured seven inches and upwards.

I have already stated, that the occurrence of profuse menstruation was the earliest and commonest symptom of enlargement of the uterus the result of subinvolution. This is so generally the case, that I have drawn the inference that the occurrence of profuse menstruation in cases of retroflexion of the uterus proved that the flexion was a secondary affection, the result of subinvolution of the uterus, and I still believe that as a general rule, this is correct, but there are exceptions, however, to this rule.

2. The occurrence of enlargement of the uterus from any cause suddenly checking menstruation is by no means rare, but the opportunities of proving this to be the case do not frequently occur; for if an unmarried woman complains of fulness, of pains in the head and in the back, of a sense of weight in the pelvis, and states that menstruation has been checked by exposure to cold or by some other obvious cause during the catamenial period, we are probably satisfied that uterine congestion exists; but, we are not justified in making a vaginal examination of any kind, unless, indeed, after a protracted trial, general treatment fails to relieve her. Again, if a married woman exhibits the same train of symptoms, the possibility of pregnancy existing precludes the use of the sound. Recently, however, I had an opportunity of verifying the fact. A widow, the mother of thirteen children, in whom menstruation had been irregular for three years, had in June last, after a long interval, a return of the discharge. It ceased suddenly, and she suffered great discomfort from a distressing sensation of weight and bearing down in the pelvis, and of fulness and pain in the head. In her case the uterus was three inches in depth, while all the symptoms rapidly subsided under treatment. It may be objected that, in this case, we were ignorant as to what might have been the condition of the uterus previously; but, here was a woman in the enjoyment of good health, suddenly attacked, after the abrupt checking of menstruation, with distressing symptoms, in whom the uterus was proved to be enlarged, and who was relieved of those symptoms and of that condition by treatment. Is it not then fair to reason that the enlargement was a temporary condition, the result of uterine congestion, itself caused by the sudden checking of menstruation?

3. All modern writers agree that acute inflammation may produce enlargement of the uterus, and I believe that this may

be the case, whether the patient suffers from peritonitis, metritis, or pelvic cellulitis. Of the two latter I have no doubt. Of enlargement of the uterus as the result of peritonitis, I had no experience till very recently, but the following case throws some light on the subject:—

Mrs. K., æt. 33, was admitted into the Adelaide Hospital in May, 1870. She was the mother of three children, the last of whom was born in March, 1869, fourteen months previous to admission. It appears that four weeks after her confinement, having been exposed to cold, she was attacked with severe pain over the whole abdomen. This pain, after a time, became localised in the left iliac fossa; and by degrees it, in a great measure, though not entirely, disappeared. At the expiration of two months from the date of this attack menstruation came on very profusely, and lasted for six weeks. She now obtained medical advice, and was treated for ulceration of the os uteri; but, although the menorrhagia was in some degree checked, the pain from which she suffered again became very severe. On admission into hospital the uterus was found to be retroflected, a certain amount of granular erosion existed, and menstruation was profuse. Her greatest distress, however, arose from an incessant dragging pain which she referred chiefly to the situation of the transverse colon. The uterus was enlarged to a trifling extent. The use of a pessary and other appropriate treatment speedily improved the condition of the womb, and she returned home apparently cured. At intervals, however, she still suffered from attacks of the abdominal pain. In the beginning of October she again caught cold, and was re-admitted into hospital labouring under a well-marked attack of sub-acute peritonitis. Leeches, fomentation, and the exhibition of opium relieved her. During the course of this attack I twice measured the depth of the uterus, and found that it had increased nearly an inch in length. She did not menstruate during this attack.

This case contrasts strongly with one referred to on a former occasion, in which menorrhagia and pain of a paroxysmal character, referable to the uterus, were the prominent symptoms. It illustrates the occurrence of enlargement of the uterus as the result of endo-metritis.

4. Chronic inflammation of the uterus being more frequently met with than the acute form, is a more common cause of enlargement. Such cases are constantly coming under observation. They are frequently found in connection with retroflexion of the uterus. Of course all are aware, that it is a disputed point whether flexions of the uterus are a cause or a result of inflammation. For my own part, I am far from denying that flexions of the uterus, but more especially retroflexion, may take place independently of inflammation, still, I am satisfied that in the majority of cases, inflammation, or at least active congestion, is the primary and principal cause of these flexions, and this opinion, which I expressed in a paper published two years ago, enlarged experience has since amply confirmed. In such cases the symptoms are often very distressing. The following typical one, at present under my care in the extern department of the Adelaide Hospital, illustrates this:—

E. D., æt. 30, seven years married, has never been pregnant; about three or four years ago began to suffer from pain in the back, over the pubis, and in the left groin. Menstruation is scanty, and is occasionally suppressed for two or three months at a time. Sexual intercourse is painful. On examination, I found the uterus elongated and retroflected. This case, although an aggravated one, is typical as showing the sufferings due to enlargement of the uterus the result of chronic inflammation.

In each of the foregoing cases, the enlargement evidently appears to have been due to inflammatory action attacking a uterus previously healthy, so far at least as we had opportunities of judging; but, in some instances it seems to follow as

the result of the treatment we have been compelled to adopt for the cure of other ailments. Eighteen months ago, I was consulted by a lady for menorrhagia. She was married but had never become pregnant. For a year previous to marriage, menstruation had been more profuse than formerly, but not to such an extent as to attract much notice. Since marriage, however, she had become worse, and at the time of her consulting me, not only was the discharge very profuse, but it also generally continued to flow for more than a fortnight. A vaginal examination detected extensive granular erosion of the os and cervix uteri. This condition was in time perfectly cured and the menorrhagia consequently ceased; but, I observed, that as this condition of the cervix improved, so did the uterus enlarge, the fundus becoming heavy and globular in shape; and yet, my treatment had not been characterised by the use of any severe remedy. I had hoped that after the unhealthy condition of the cervix had been cured, and all treatment had been discontinued, the uterus would regain its normal size and shape, but I regret to say such has not as yet, at least, been the case. I had an opportunity of seeing this lady a few days ago. The uterus, after the lapse of a year, remained unaltered; the fundus is quite globular; menstruation is scanty and occasionally painful. She has never conceived. My retrospect of this case is, that the treatment which it was absolutely necessary to adopt to check the hæmorrhage and cure the unhealthy condition of the uterus, excited a certain amount of inflammation of the uterine tissue, which has resulted in permanent enlargement of the organ. A similar result, I am satisfied, not unfrequently takes place from congestion and chronic inflammation, unconnected with any ulceration whatever.

5. Next I shall call your attention briefly to that condition, which, for lack of a better name, I term hypertrophy of the uterus. I mean to include under this head those cases in which the whole of the uterus, or some portion of it, slowly and imperceptibly increases in size. Sometimes the cervix alone is implicated, that portion of the organ becoming elongated and thickened, or the body alone may be affected, while in other cases the body and cervix are equally engaged, and become thickened, enlarged, and frequently painful. The pain being apparently due either to hyperæsthesia of the nerves of the uterus, or to the pressure exercised on them by the hypertrophied tissue by which they are surrounded.

In these cases menstruation, as a rule, is but little altered in its character; sometimes it is slightly diminished in quantity, and not unfrequently becomes painful, but I do not remember meeting with a case in which hæmorrhage was present. I am of opinion that the condition of the menstrual functions will materially aid our diagnosis in doubtful cases; for if the enlargement be due to chronic inflammation, it will most probably be lessened in quantity; if to subinvolution or to the presence of any intra-uterine tumour, it will in general be augmented; while in cases of simple hypertrophy it is seldom altered, at least in any great degree.

The pathology of this form of uterine enlargement is very obscure; the fibres composing the muscular tissue of the uterus appear to be elongated and thickened, while there is also hypertrophy of the areolar tissue. Both conditions may have their origin in a low form of inflammation which at the time escaped observation; but we cannot, in the present state of our knowledge, say, why in a certain case the cervix uteri elongates and enlarges, till by its very size and weight it irritates and causes distress; while, at the same time, in another the body and fundus of the uterus participating in the unhealthy condition of the cervix, become heavy and elongated; and in another, seem to remain in their normal condition. Excessive indulgence in sexual intercourse has been set down as a cause of enlargement and hypertrophy of the cervix, but I doubt this much. In my own practice, the case which

of all others gave rise to the greatest amount of suffering and distress, occurred in an unmarried woman. Miss —, æt. 40, came under my care nearly two years ago. She stated that about seven years previously she, for the first time, experienced pain in the back and over the pubes, and not long after a sense of weight in the pelvis, and that her suffering had ever since gradually increased. When I saw her she could not sit up for any length of time, and walking, even a short distance, caused much distress; she also complained of a troublesome itching at the vulva. On instituting a vaginal examination, the cervix was found to be elongated to the extent of at least an inch. It was thickened and hypertrophied, the supra-vaginal portion evidently participating in the abnormal condition of the organ. Menstruation continued to be performed regularly, but it was attended with much pain. She has ever since been under observation, though I have long ago abandoned any active treatment. This lady has been treated by leeching, by blistering, by the administration of the iodide of potassium and of the bichloride of mercury, and it is hard to say which of these did the least amount of good. The uterus has steadily increased in size, evenly and universally, and with its increase so have her sufferings increased, till now she has become a complete invalid. In her case I at one time, before the body of the uterus became so manifestly enlarged, entertained the idea that amputation of the cervix might, by removing the cause of local vaginal irritation, be productive of benefit. But, as the operation certainly was not entirely free from risk, and as I became satisfied that the supra-vaginal portion of the uterus also participated in the diseased condition, I abandoned the idea. In this case I feel perfectly satisfied that the hypertrophy commenced at a very early age and gradually increased; it bears a strong resemblance to one recorded in Vol. II. of the work on "Diseases of Women," by Bernutz and Goupil, published by the Sydenham Society. Another case of hypertrophy of the cervix in an unmarried woman has since come under my observation. She is a dressmaker, æt. 28, an industrious woman, sitting at work upwards of twelve hours a day. She complained of weight in the pelvis and of bearing down. She also suffered from the most obstinate constipation. Menstruation was regular, but generally accompanied by pain. On making an examination the os uteri was found to rest on the perineum; the cervix was elongated and thickened, and the fundus slightly enlarged. This woman would not come into hospital, and consequently I have had no opportunity of trying the effects of treatment, from which, in truth, I would anticipate but little benefit.

Any person who has read the work just mentioned will at once see that the condition I am now referring to is very similar, if not analogous, to that termed by M. Huguier, "hypertrophic allongement" of the uterus, a condition which he divides into two classes—namely, sub-vaginal and supra-vaginal, a division the actual value of which I do not highly appreciate. I am inclined to the opinion that, although we may have enlargement of the body of the uterus without the cervix being engaged, the cervix is never enlarged for any length of time without the supra-vaginal portion of the organ becoming implicated in the disease. I also believe that not a few of the cases recorded by M. Huguier were cases of subinvolution of the uterus following delivery, and not of the condition which I have termed hypertrophy.

But, in addition to these cases of hypertrophy with elongation of the cervix or of the body of the uterus, or of both, we meet with cases in which there is no elongation, but the very reverse. We sometimes find the cervix shortened, drawn up, as it were, into the body of the uterus, and some-

times disappearing altogether. In such instances the body of the uterus assumes a globular form. This form of enlargement gives rise to considerable distress, and it seems specially to cause intractable irritation of the bladder. In one case, which was for years occasionally under my observation, this symptom was the prominent one, and that for which the patient sought relief.

There is no form of uterine disease in which so little good can be effected by treatment as that to which I am now referring. If the body of the uterus be engaged, it seems nearly useless. If, however, we are satisfied that the cervix only is affected, amputation may be resorted to with advantage; or possibly local depletion and subsequently the repeated application of Dr. Greenhalgh's iodized cotton may effect some good.

It remains for me to allude, and I shall do so very briefly, to that form of uterine enlargement in which the organ is stimulated, and increases in size, from the presence of a fibrous tumour embedded in, or growing from, some portion of its walls. Cases are recorded in which a fibrous tumour of very small size, perhaps not larger than a nut, so stimulated the uterus that it increased to five or six times its normal size, the cavity too being proportionally elongated. These cases are most perplexing, a *post-mortem* examination alone being capable of revealing their true nature. Fortunately they are not of frequent occurrence. I have not myself met with any case in which I was satisfied of their existence. In the great majority of instances a fibrous tumour sooner or later will bulge into the cavity of the uterus, or project out on the peritoneal surface. In either case the tendency of the disease is to render menstruation more profuse; while in that form of enlargement depending on hypertrophy of the fibrous tissue of the uterus, and which is the only form liable to be confounded with the one now under consideration, menstruation, if interfered with at all, is more likely to be diminished than increased. The subject of fibrous tumours of the uterus does not come within the scope of the present lecture. I wish, however, to draw attention to those cases, of by no means infrequent occurrence, where enormous fibrous growths exist in which the womb is embedded and almost lost. These cases have over and over again been mistaken for ovarian tumours, a mistake which the use of the uterine sound may help us to avoid. It tells us not only what is the length of the uterine cavity, but also whether the uterus is free or embedded in the tumour.

Now, as to diagnosis. I have already stated that the sound and that alone enables us to decide as to whether the uterus be enlarged or not, but it affords us no clue as to the cause of the enlargement. A few general rules, however, if they do not enable us to give a positive diagnosis, will at least facilitate materially our decision as to the nature of any case. Thus, if we meet with an enlarged uterus in a woman who has aborted or been delivered at the full time, even though a considerable interval has elapsed, the probability is in favour of the enlargement being dependent on subinvolution, and this opinion will be confirmed if, as is nearly always the case, menorrhagia be present. If again metritis, pelvic cellulitis, or peritonitis be present or have occurred recently, the inflammatory action is fully sufficient to account for the condition of the uterus, and it should be always borne in mind that it does not follow that the enlargement will disappear with the subsidence of the inflammation; so again, in other cases, we should ascertain if menstruation has been checked or suppressed, and if symptoms

referable to the uterus have followed on this; or if again, pain in the back and over the pubes was first noticed, menstruation being subsequently lessened or suppressed: in the former case we are likely to find that the enlargement depends on congestion, in the latter on chronic inflammation, while hypertrophy steals on gradually, menstruation being seldom interfered with; and it is of no small importance to decide to which cause the enlargement is due, for while much may be done to relieve the sufferings caused by enlargement of the uterus the result of chronic inflammation, treatment seems utterly powerless in alleviating those produced by simple hypertrophy of the uterus. It is, indeed, a nearly hopeless ailment, one not likely to destroy life, but to render it a burden. Then, again, if we have menorrhagia in cases of enlarged uterus, unconnected with any of the causes noticed, we may expect to meet with intra-uterine polypus, or fibrous tumours. It will then be our duty to clear up the doubt which exists, by dilating the cervix and exploring the interior of the uterus.

As I have called your attention to the subject of enlargement of the uterus, with the hope that I may aid you in arriving at a correct diagnosis in cases in which that condition exists, I shall not enter at any length into their treatment; that of subinvolution was fully discussed on a previous occasion (Lecture V.), and I must refer you to what was then said on the subject.

In cases of enlargement following sudden suppression of menstruation, the administration of saline purgatives, and subsequently of the bromide and iodide of potassium conjointly in full doses, will generally, if the case be recent, prove sufficient; but should it be neglected in the early stages, it will probably pass into the condition of chronic inflammation, a condition over which medicines possess little influence. The prolonged use of the bichloride of mercury, in small doses, has been recommended in these cases, but in my own practice I have not been satisfied that it produced any good effect. I have seen, I think, more benefit result from local depletion by puncturing the cervix uteri, as recommended by Dr. Hall, of Brighton, than from anything else, and I think it is a mode of treatment deserving a fair trial. To be of use this must be repeated frequently at intervals of about five days. The application, to the verge of the anus, of two or three leeches, immediately after the termination of a menstrual period, where menorrhagia is present in connexion with a relaxed and engorged uterus, also often proves beneficial. Both these methods act by relieving the congested condition of that organ, and thus facilitating its contraction. In conjunction with this treatment, I recommend the administration of strychnia with the addition of dilute nitric acid, or, if the patient be anæmic, with the tincture of the perchloride of iron. Strychnia is the most valuable medicine we possess in case of menorrhagia in connexion with a relaxed atonic condition of the uterus. It is, however, contra-indicated in cases of chronic inflammation, unless that condition be first relieved by local depletion.

In cases where the uterus has become enlarged and hardened, as the result of chronic inflammation, the use of the waters of Kreuznach seems to have a very beneficial effect, and if the patient's means are such as to admit of her visiting that place, a trial should be made. As to hypertrophy of the uterus, treatment is seldom likely to effect good.

In cases of enlargement of the uterus from inflammation of an acute character, I believe rest, the exhibition of opium, and warm poultices over the abdomen to be the means on which we should rely; depletion, if practised at all, should be in a limited degree by the application of a few leeches. Mercury I consider to be not only useless but actually deleterious.

Special Report

ON

DISEASES OF THE THROAT.

Edited for the "MEDICAL PRESS AND CIRCULAR."

By PROSSER JAMES, M.D., M.R.C.P.,

Physician to the Hospital for Diseases of the Throat and to the North London Consumption Hospital; Lecturer on Materia Medica and Therapeutics at the London Hospital.

III.—LARYNGOSCOPY.—(Continued.)

The Laryngeal Image. The Vocal Cords. Other Parts Reflected. Parts of the Cavity of the Larynx. Appearance of the Cords.

WHEN the mirror has been introduced and the full light directed upon it the operator will have a view of the parts in the line of reflection.

If the directions already given have been followed and the conformation of the parts be normal, an image of the interior of the larynx occupies the mirror, the vocal cords arresting attention by their movement as well as by their white colour, which is in striking contrast with the surrounding parts.

If the mirror should not have been carried far enough back—a common error with beginners—or if it be otherwise improperly placed, of course this view will not be obtained. In the former case rectification is easy, in the latter the mirror should be withdrawn and re-introduced.

It is not uncommon for the beginner to see only the base of the tongue and upper surface of the epiglottis, or if he have carried his mirror far enough he may even then only see the under surface of the epiglottis.

I have even known the mirror to be so held at first as only to reflect some of the teeth, and yet the learner has very soon become an efficient laryngoscopist.

To some beginners, the sudden appearance of the teeth instead of the vocal cords in the mirror, is quite startling. A moment's consideration of how they are holding the mirror removes their perplexity.

The view, moreover, will vary somewhat with the conformation of the individual, but most of all with the angle at which the mirror is held, and this may be varied to any extent.

A single demonstration will suffice to teach a pupil so to hold the mirror as to see the vocal cords in action.

It is easier, in fact, for a student to learn this from a competent professor than to comprehend and appreciate the printed directions.

I speak of the vocal cords, because in his very first lesson the student ought to see them distinctly and notice their vibration. From that moment he will never forget their appearance and he will feel more interest in his work; moreover, they will serve as land marks for the study of other parts of the larynx. The laryngeal image is seen in Fig. 13,

FIG. 13.

which represents the mirror (B) held over the larynx (A) and reflecting an ordinary view of the cavity.

In this figure, A is the anterior view of the larynx, merely introduced to show its relative position to the mirror B, in which the reflected image appears. The epiglottis is marked *a* in both figures. The right and left vocal cords of the patient are marked *r* and *l*, and the arytenoid cartilages, which are also prominent parts in the view, are marked *b* and *b'*.

In the next figure (14) there is presented a view of

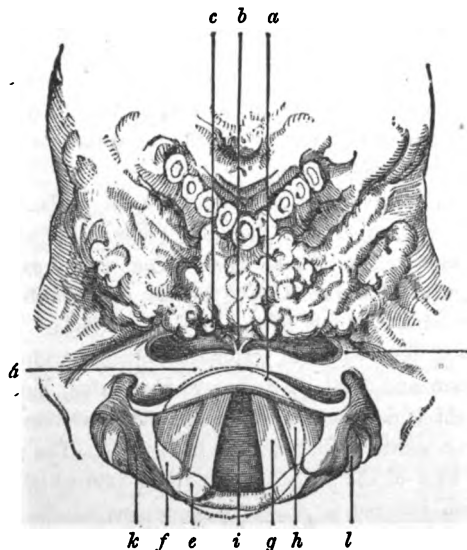

FIG. 14.

nearly all the parts likely to come into view in the attempt to see the interior of the larynx. The laryngeal image, as seen in a moderate sized mirror, is included in the dotted circle. This engraving is copied from Türk (*a*), with the exception of the dotted circle, which was added by Dr.

(a). Klinik der Krankheiten des Kehlkopfes. Wien., 1866.

Walker (a)' Several parts, such as the base of the tongue, will at once be recognised, while the laryngeal image is more complete than in Fig. 13. Thus the letter *g* points to one of the true vocal cords, while *h* indicates one of the so-called false cords; *i* is the rima glottidis or opening between the true cords; *e*, the arytenoid cartilage surmounted by the capitulum Santorini, and close to this is the cartilage of Wrisberg, *f*.

The epiglottis is marked *a*, as in the previous figure, *b* is the glosso-epiglottic ligament, and *c* the valæcula.

It may be thought that the crowding of these parts into one engraving is unnatural. Still the figure gives a fair idea of the relative position of the parts likely to be reflected in the mirror during the student's early attempts to explore the larynx, while the dotted circle directs his attention to the ordinary laryngeal image. With every detail of this image he must be thoroughly familiar, and he will soon find that in the normal condition it varies considerably in different persons. Moreover, he will be prepared to watch its extensive changes during respiration and phonation. To assist in the recognition of the several parts an unlettered engraving of a laryngeal image is here added.

FIG. 15.

This, it will be observed, is a fuller view than the preceding one. The cushion of the epiglottis is distinctly seen immediately under its lip. The glottis itself is not quite so open, and there are some other differences between the two figures of which the student should make a careful comparison.

I have already remarked that the vocal cords are in remarkable contrast with the other parts. It is impossible, therefore, to mistake them. They appear as two flattish, white bands connecting the base of the arytenoid cartilage with the angle of the thyroid cartilage. They are seen to move with the respiration, opening widely in inspiration and partially closing in expiration, but the movement is most posteriorly, where the separation may be from a quarter to half an inch in distance. The angle at the base of the arytenoid cartilages into which the cords are inserted is called the processus vocalis. As the vocal cords approximate this angle is turned inwards, but when they separate it turns outwards, so that in inspiration the glottis has what has been called a lozenge-shape. The vocal process above described served Longet for a division of the glottis into the inter-cartilagenous and inter-ligamentous portions.

(To be continued.)

NEW METHOD OF PUTTING UP FRACTURED CLAVICLE.

By DR. LEWIS A. SAYRE, OF NEW YORK,

Professor of Surgery in the Bellevue Hospital Medical College.

THE *American Practitioner* for July, 1871, contained a description of a method of dressing fracture of the clavicle, which we are assured will commend itself to our readers. It is thus described:—

“Strong and good adhesive plaster (Maw’s moleskin is the best) is cut into two strips, three to four inches wide (narrower for children); one piece long enough to surround the arm and go completely around the body, the other to reach from the sound shoulder around the elbow of the fractured side and back to the place of starting. The first piece is passed around the arm just below the axillary margin, and pinned or stitched in the form of a loop sufficiently large to prevent strangulation, leaving a portion on the back of the arm uncased by the plaster. The arm is then drawn downward and backward until the clavicular portion of the pectoralis major muscle is put sufficiently on the stretch to overcome the sterno-cleido-mastoid, and thus pull the inner portion of the clavicle down to its level. The plaster is then

Sayre's first bandage for fractured clavicle.

carried smoothly and completely around the body, and pinned to itself on the back to prevent slipping. This first strip of plaster fulfils a double purpose: first, by putting the clavicular portion of the pectoralis major muscle on the stretch, it prevents the clavicle from riding upwards; and secondly, acting as a fulcrum at the centre of the arm, when the elbow is pressed downward, forward and inward, it necessarily forces the other extremity of the humerus (and with it the shoulder) upward, outward, and backward; and it is kept in this position by the second strip of plaster, which is applied as follows: Commencing on the front of the shoulder of the sound side, drawing it smoothly and diagonally across the back to the elbow of the fractured side, where a slit is made in its middle to receive the projecting olecranon. Before applying this plaster to the elbow, an assistant should press the elbow well forward and inward, and retain it there, while the plaster is continued over the elbow and fore-arm (pressing the latter close to the chest, and securing the hand near the opposite nipple); crossing the shoulder at the place of beginning, it is there secured by two or three pins.

Sayre's second bandage for fractured clavicle.

“When this has been done, the deformity will have entirely disappeared, the fractured bones will be accurately adjusted, and as long as the strips of plaster maintain their position, no amount of force can displace them.”

BRITISH MEDICAL ASSOCIATION.

ADDRESS IN MEDICINE.

By SAMUEL WILKS, M.D., F.R.C.P., F.R.S.,

Physician and Lecturer on Medicine at Guy's Hospital, Examiner in Medicine at the Royal College of Surgeons, &c.

(Continued.)

I MUST say yet one word more in favour of the study of morbid anatomy—its necessary aid to diagnosis. No

amount of clinical observation or acumen could enable the Medical man to form an opinion of the nature of many cases without an acquaintance with the diseases which *post-mortem* examination alone can reveal. This implies that symptoms do not carry with them the interpretation of their cause; that symptoms are not, in fact, pathognomonic. The time has not yet arrived to enable us to associate symptoms with certain definite lesions, and we must be content at present to act on the doctrine of probabilities. When a cancer in the chest will produce the same symptoms as an aneurism, or an arachnitis the same cerebral symptoms as a diseased kidney, our diagnosis must rest on other considerations than symptomatology, and we are led to guess in one direction rather than another from extraneous facts. A slight sore throat in a boy at school where the epidemic of scarlatina exists, suggests this disease, not from the symptoms but from a knowledge of its presence in the house. Diagnosis being thus made by considering the probabilities in favour of the existence of one disease rather than another, in order to form a judgment, a thorough acquaintance with all diseases is necessary, and the man who has the largest knowledge of morbid states is he who will most likely arrive at the surest conclusion. It is clear then that mere acumen at the bed-side is not sufficient; the quick eye and ear may discern all that can possibly be learned, and yet the interpretation may be wanting, simply because the observer has not had a sufficiently extensive knowledge of all the phases of disease by which he can explain the symptoms. This fact I have constantly observed. Therefore, if it be true, as I think it undoubtedly is, that that man forms the best opinion of a case who has the widest experience of disease, it follows that not only is a study of the living necessary to diagnosis, but also that of the dead. Diagnosis is made up of two parts—the symptoms and their interpretations. The first is gained by clinical observation, the second by a knowledge of all the diseases to which the human body is liable. We have to try and discover all the ills, functional and organic, to which flesh is heir; and we then, in the living subject, watch the symptoms which are associated with them. In any given case we first take the symptoms and ask what they imply; the answer should be so much and no more. Secondly, we ask what are the probabilities in favour of their connection with one particular disease rather than another. The answer is the diagnosis. A study, then, of morbid anatomy, by making us acquainted more exclusively with diseased action, is necessary for accurate diagnosis.

I have said that, with the exception of sudden attacks of inflammation in the chest arising from vicissitudes of climate, nearly all the morbid changes found in the body have been insidious and slow. These are the diseases going on within, due to causes ever operating upon us quietly, or inherited from our fathers. There is, however, an altogether different class of affections, arising from causes which attack us from without. To these we are all liable; they are the specific contagious and epidemic disorders. The difference between them appears to be marked, and their peculiarity arises rather from the nature of the external agent than from the patient or recipient. To many minds the phenomena attached to the development of each of these diseases are so uniform, that they see in every individual example the offspring of a common stock; and they are strengthened in their view by the fact that the virus taken from a particular victim will grow and spread like a seed from its parent plant. They believe, therefore, in the possibility of stamping out contagious diseases, just as they might exterminate a particular animal or tree. There are other persons, however, who, whilst believing in the specific nature of these diseases, yet hold that they can be spontaneously generated, as, for example, typhus, from the crowding together of many people; typhoid, from decomposing vegetable matters; scarlatina, from decomposing blood; and, according to Miss Nightingale, small-pox, under various conditions of foul air. There are, however, yet others who, believing that specific causes are in operation, yet do not hold that they are necessarily propagated or generated in the animal body, but have an independent existence outside the human frame in the form of vegetable germs; for example, the element of cholera is, according to them, a rice fungus, that of measles a fungus of another species, and the virus of typhoid a third. If the analogy at all hold good between the phenomena of these diseases and those of animal or vegetable life, the con-

clusions would rather be in favour of each particular example of the disease having its origin in a parent source; and thus, as in the case of every weed in our garden, we assume that a seed has been planted in the soil, and leave it to others to prove its spontaneous growth, so, from analogy of reasoning, in the case of specific contagious diseases, we would leave the *onus probandi* to those who deny the more obvious explanation, and seek for another in the doctrine of spontaneous generation. Whatever may be the view we take, if we regard these diseases as in any way likely to have been produced by specific organic particles rapidly growing in a favourable soil, we cannot regard with any satisfaction the doctrine of elimination. According to the generally received views the virus, as that of small-pox, being inserted into the system, begins to grow and propagate in the soil until the process of development is complete, it may be to the actual destruction of the soil in which it has flourished. I cannot see anything like elimination in this, but rather a rapid and active growth, destructive in its progress. If the soil be not fitted for it, the germ may wither, but the abortion seems by no means due to any eliminative powers in correspondence to the youth or strength of the patient, but to an entirely different class of circumstances. I confess, if I knew the method of killing the virus at its source, or staying its growth, I should be inclined to do so rather than foster its development; and, if it be true that the specific diseases are due to the introduction of an organism into the blood, then all must agree that this treatment is rational. A ringworm grows and grows wherever the soil is propitious; the itch insect spreads over the body; and the hydatid often swells until its host is destroyed. Cancer cells divide and propagate until they have killed their victim which has supplied them with nourishment; and the germs of small-pox will do the same. In none of these cases do I see any special power possessed by the body which can be called eliminative. If the cause, then, of specific diseases be due to germs, and these should be shown, as in the supposed case of cholera, to be nothing but a vegetable fungus, the analogy between such diseases and the parasitic, as shown by the result, is complete. The specific diseases then afford another example of what is witnessed throughout all nature—that the life of one is dependent on the destruction of another. There is a constant struggle for existence amongst all living things in creation; they are all living on others whilst endeavouring to protect themselves, and man is not an exception.

"While man exclaims 'see all things for my use,'
'See man for mine,' replies a pampered goose."

The whole history of a living thing is not told unless it be shown what kind of prey it is to others. The naturalist, in describing the sheep, shows its digestive apparatus and appropriate food, and finally now it becomes meat for man; or a fish in all its anatomical and physiological details, and then how it becomes the prey of some larger creature. The naturalist, too, in describing the hydatid, from a hydatid point of view, would show its means of sustenance, and how some species rejoiced to feed on the liver of man; or how the trichophyton tonsurans found a favourable soil in the human head. I do not see any special power in the human body to get rid of these parasites; all I see is, an open war being waged between the guest and the host as to the mastery; each is trying to thrive, and consequently destroys the other. Would not the ivy, in writing its life, speak of its claspers by which it embraces the elm; and would not the elm speak of its destruction by the ivy? Would not the pretty dodder speak lovingly of the gorse, which it, nevertheless, often chokes? I think the philosophy of the whole matter is found in *Hamlet* when the Prince says to the King:

"We eat all creatures else to fat us, and we fat ourselves for maggots. Your fat king and your lean beggar is but variable service two dishes to one table.—Alas! alas!—A man may fish with the worm that hath eat of a king, and eat of the fish that have fed of that worm!—What dost thou mean by this?—Nothing, but to show you how a king may go a progress through the guts of a beggar."

In the case of parasites, it is clear that we have no inherent power to get rid of them, and all we can attempt to do is to destroy them by violence. If there be any truth, therefore, in the germ theory of contagious diseases, the treatment of them is clear—war to the knife. The analogy would not be so close, if it were true that the weakly and the sick first became a prey to epidemic disease.

This has often been stated by writers on social science, when conformable to their views; but facts are antagonistic to them. I have always taught the opposite, and can now speak with confidence since Dr. Walshe, in a lecture lately published, has expressed the same opinion. Many years ago, when reporting cases of fever, I said that I had never found any organic disease in those who had died of it, for it was not until typhus had broken out in the hospital, and after many years' experience, that I had an opportunity of seeing such a thing as a diseased heart in a person dead of fever. I think all members will bear me out in saying that it is amongst the youthful and vigorous that small-pox, scarlatina, &c., grow and prevail. From their own germ point of view, these diseases delight in the young and healthy; and, in the case of artificial poisons or those introduced into the system by accident, I see no effort of nature to get rid of them. The kidney, like every other organ, has its own peculiar function, and takes cognizance of certain materials in the blood and eliminates them; but it often seems to have no power to eradicate them from the system, for, in the case of lead-poisoning, the blood may throw them down in every tissue of the body, and there leave them.

Whilst on the subject of elimination, and the supposed efforts of nature to get rid of deleterious matters from the system, it might naturally be conjectured that, with the rejection of this doctrine, I should discard all such ideas as are conveyed in the terms, "conservative processes," and the "vis medicatrix nature." The supposition is right; and I would more fully have dwelt on the subject, had not Dr. Bristowe so admirably treated it in the Croonian lectures lately delivered at the Royal College of Physicians. He has put it very clearly before us, how certain physiological laws exist which we can watch like other laws in nature, and see how they always act in certain definite methods; further than this we have no right to go. We have no right to select a particular instance of a natural process, and declare that a conservative action is in operation, any more than choose another case and call the action destructive. The forces of nature go blindly on, heedless of results, and cannot be spoken of as if they were half intelligent powers with benevolent or baneful objects in view. Such notions would show that we had not reached the true scientific method, but, according to Comte, were still in the metaphysical stage of thought, when external agencies were supposed to be ruling the world. If we once admit them into our nomenclature, we are led into countless contradictions. If, instead of regarding the hypertrophy of the ventricle, in the case of obstruction of the blood-vessels, as a result of a simple physiological law, we speak of it as a conservative process, we are immediately reminded of the wrongfulness of the expression, when we see this same conservative process causing the rupture of a vessel in the brain, and killing the proprietor; or if we choose to call the blocking-up of the blood-vessels as they pass through a cavity in the lung, conservative, how are we to name the same process when it tends to the mortification of an organ, and perhaps the death of the patient? These laws are natural laws, and often not even strictly physiological; for where is the difference between the case of enlargement of the superficial veins when the vena cava is obstructed, and that of dirty water finding its way by the gutters when the main sewer is choked? If a conservative power preside in the one case, does it not in the other? I may be allowed to say that I do not take up this subject as the question of the hour, but am giving you the result of my matured thoughts, and such as I have always taught. I have always regarded such terms as, conservative, elimination of disease, "vis medicatrix," as purely metaphysical, and having no place in the vocabulary of medicine. This last term I discarded from my earliest student days, for I well remember when a surgical teacher used the expression with reference to a case of fractured skull, and when, notwithstanding that curative nature was to step in and mend it, the patient was seen on the *post-mortem* table a few days afterwards with inflammation of the brain; I remarked, in terms which were considered almost sacrilegious, that the man would have lived with a crack in his skull if nature's vis medicatrix had not stepped in and killed him. I am convinced that, when we occupy our minds with metaphysical entities, and talk of conservative powers of nature, vital principles, and such like vague terms, we are hindering scientific discovery, by implying that there are agencies at work behind the phe-

nomena which we witness. I confess I do not know the intentions of nature, and whether, when a man is purged in cholera, nature is endeavouring to cure him or to kill him. The doctor says the former, the social statistician says the latter. I remember, too, we used to be told that not only disease itself, but even an accident, might contain within itself the element of repair; for example, a thorn which sticks in the skin would set up an inflammation and abscess, and thus be discharged. The very source of mischief contained the cure. A very striking and ridiculous rebuff to this doctrine occurred some years ago at my hospital, in the case of a young man who, having had too much to drink, fell off a plank whilst crossing to his ship, and was nearly being drowned. On his recovery, he was lectured on the serious consequences of spirit-drinking; whereat he replied that, on the contrary, he had been informed that it was nothing but the brandy in his stomach which had restored him to life.

Next to the evil of allowing some metaphysical idea to influence our mind is the fault of taking a scientific fact or principle, and making it explain a number of obscure phenomena without our possessing any data to guide us as to the correctness of the application. With one, a chemical theory is made to solve all abstruse questions in physiology and pathology; with another, cell-growth can do the same; and with a third, a nervous influence can accomplish all things. See, for example, what a remarkable experiment of Bernard has done for us. He divided the sympathetic in the neck of a rabbit, causing the temperature to rise, and the part to become more vascular. It seemed clear from this experiment, that the vascular supply is dependent on nerve influence, and thus we are introduced into a new domain of vaso-motor and trophic nerves. What has been the consequence? Every ingenious man has sat down in his study, and assisted to flood Medical literature with explanations of physiological action, morbid processes, or the therapeutic operation of medicines founded on the theory. Nearly every disorder of the nervous system, be it of an apoplectic or convulsive nature, as well as a large number of other morbid phenomena, can be now accounted for on the theory of an altered vascular supply through the vaso-motor nerves. The operation of many drugs is now made apparent by the influence they exert on nutrition through these nerves, the only difficulty being in the fact that the medicines have different actions, whereas the vessels are only susceptible of dilatation or contraction. It is for this reason that theoretical men have found strychnia and belladonna the two great agents for rousing and depressing the nerve-centres, thus enabling them to hold in their grasp the maladies supposed to be dependent on their rule. This great idea has been much simplified by substituting heat and cold, and thus these nerve-governing powers of the human body being stimulated to increased action by the one, or their over activity controlled by the other, every single complaint to which the human body is liable can now be cured, and all by means of spine-bags. I take this as one example of our eagerness for more knowledge; there are very few on this earth who are presenting us with new facts, or, rather, revealing to us some hitherto hidden secret of nature; and when they do bestow upon us the result of their labours, we grasp it, we hug it, we cannot make enough of it, until in the end we all become ridiculous. What we want are more facts and more truth; the praise cannot be too great which is bestowed on those who are silently working in their laboratories for our advantage. It is more light and knowledge that we want. I might here remark, that I believe it is the suppression of theory, and the keeping to facts, which has placed the Pathological Society of London in so eminent a position; and, to my mind, the more it has kept to dry, morbid anatomy, the more successful has it been. Those who talk of grouping together facts, and speak of our dead pathology, can scarcely be aware of the material which is required before this can be done. How much do we know, I might ask, of the changes in the brain, spinal cord, and ganglionic system, so as to associate them with living symptoms? The whole lies before us as an undiscovered country. So difficult does it seem to keep the great dictum of Bacon before us, and regard ourselves as the interpreters of Nature, and not invent false theories to ourselves, which are only "the children of an idle brain." I believe Ruskin is not far wrong when he says, "The more I think of it, the more I find this conclusion impressed upon me; that the greatest thing a human soul ever does in this world is to see

something, and tell what it saw in a plain way. Hundreds of people can talk for one who can think, but thousands can think for one who can see."

If, then, we are struggling on, our facts scanty, our pathological ideas narrow or false, how is it possible that the art of cure can have a scientific basis? I have ever maintained, and must do so still, that our treatment at present is necessarily empirical. Even those who maintain the contrary, and found their opinion upon the newly discovered property of a drug to-day, are tacitly admitting that they must have worked in ignorance yesterday. A scientific treatment appears to me to require a thorough knowledge of disease to understand the meaning of the symptoms, and then to have a better acquaintance with the action of drugs. Why, look at the pulse; every one can feel a pulse and understand its indications, except some of those clear-sighted men with whom we sometimes meet, and who declare that it takes a lifetime to understand its significance. Think for a moment of the pulse and some of the more evident circumstances which must influence it, or rather regard it as the resultant of a number of forces variously combined; why, the machinery is far more complex than any you manufacture in this town. There is the ventricle itself, affecting the pulse by the force, number, and regularity of its beats; then there is the condition of the orifice; then of the blood-vessel, its size and elasticity; thirdly, the state of the channels into which the fluid flows; again, the receptacles beyond them, and their facility or not of receiving the current of blood; then there is the quality of the blood itself; and, lastly, the intensity of the controlling influence over all. That all these conditions, and even more, are at work, is seen by the varied tracings of the sphygmograph, the importance of which a distinguished physician of this town (Dr Forster) was one of the first to recognise. Now, I apprehend a true knowledge of the pulse would be the facility of appreciating how any one of these conditions mentioned was at fault; and a scientific treatment would be the appropriate remedy for it. I consider the pulse as a case showing the difficulty in acting on scientific principles; for, supposing the sphygmograph should now enable us to administer appropriate treatment, it shows that my proposition was true before its discovery. My great objection to the idea of scientific therapeutics is, that it necessarily implies acquaintance with diseased action as well as the meaning and importance of symptoms. What, for example, is the scientific treatment of cholera? "To try and check the fatal discharge," says one; "To let it flow," says another. In the meantime, and whilst the scientific question is being solved, I consider it a disgrace to the Profession that we are not yet agreed as to the best hygienic methods under which the greatest number get well. What, again, is the scientific treatment of fever? This a few years ago would have been considered decided, if unanimity implied truth; for, amongst other rules, it would have been strictly laid down that, whilst the patient should have fresh air, he must by no means be chilled. This idea, however, seems to be a mere phantasm of the human brain, for we now hear that placing the patient in a cold bath is the most successful scientific treatment. So opposed to our notions does the advisability of placing a patient in a cold bath seem, that he who had attempted it years ago would have almost regarded himself as a murderer had the patient died; yet now the treatment is considered rational. As matters of minor consideration in this same disease, we daily ask ourselves whether it is better or not to encourage the sweating; whether it is better or not to remove the articular inflammation; and we make the same inquiries with regard to many other diseases. Whilst we are asking these questions, and obtain no reply, in our present state of ignorance of the signification of symptoms, we point to the man who can show the greatest number of cures as the best practitioner, who is content at present with knowing that he has a large number of valuable drugs in his Pharmacopœia, which he finds eminently useful in particular cases; first having made the diagnosis, and then administering the drug. I believe that all reasoning on the matter naturally leads to my conclusion; but, if I look around and see what is practically being done, I feel no doubt of the justice of my remark. I see that the best advisers are those who most skillfully lead their patients through a difficult illness, guided only by experience; whereas I, on the contrary, see the very worst practitioners and the most ignorant amongst those who act on fancied scientific principles. Again, extra-professional persons, who

have no knowledge whatever of medicine, are they who are almost exclusively influenced by that kind of reasoning which is styled scientific. A sick man, you know, does not like to take his physic blindly; he will know the why and the wherefore of its administration; and the more clear it is to him that the medicine is to act on this organ, or relieve this or the other symptom, with the greater pleasure does he swallow the dose. The whole train of reasoning must be wrong in such a case; but that is of little consequence to him. All quackery has for its basis science, falsely so called; and it is because of this that uneducated persons are mostly influenced by those who purify the blood, or put fresh vitality into the nerves. I may say, moreover, that all quack systems, as well as the worst methods within the pale of orthodoxy, proceed upon the plan of treating symptoms. The more closely a Medical man adopts this method, wittingly or not, the nearer does he approach the charlatan. If what I have been saying be true, that changes in the body come about slowly and insidiously, our duty is rather to study how to check their progress, and not to devote ourselves to the treatment of the mere phenomena of the disorder. In so-called gouty persons, with malassimilation and tendency to articular inflammation and deposits of uric acid, much harm is often done by the continual use of alkalies, which often merely cover the presence of the gravel without in any way removing it; or, if the great toe be especially treated, the cause may still remain. When the body has relieved itself by these portals, it may show that the outward and visible signs, in the form of symptoms, are not to be meddled with. This, which has long been recognised in the case of gout, may be applicable to other diseases, and the relief expressed by a symptom be much greater than could be accomplished by medicine.

"Tho' when small humours gather to gout,
The doctor fancies he has driven them out."

I think few would hesitate in saying that the Medical man is doing much more for his gouty patient by prescribing a suitable regimen and medicine of that kind which operates on the assimilative organs, than by attempting to relieve particular symptoms. In like manner in a case of early phthisis, he would render better service by advising a particular conduct of life than by giving his attention to petty ailments. In acute affections the same may be said; he who treats a typhoid fever, having regard to its natural course and phenomena, would be more likely to meet with success than he who, as was done in past times, meddled with the various organs of the body, and should order vinegar rags for the head, expectorants for the chest, and astringents for the bowels. Some of our methods, without appearing so, may be equally absurd, as, for example, what was once proposed to me in a case of strangulated hernia, to defer the operation until the sickness had ceased. Our object should be to get behind the symptoms, and thus obtain a fair view of the case. Some of the most lamentable spectacles I witness occur in cases of nervous people, who, being treated according to their special wants, have procured for themselves a permanent place on the doctor's sick list. It is quite true that patients do not want to know anything about pathology; they have their aches, pains, and troubles, and for these they seek advice. It is of course the province of the Medical man to heed these troubles, and endeavour to relieve them; but, nevertheless, I contend it is his duty to take, if he can, a just and comprehensive view of the whole case, and, whilst administering to the wants of the patient, yet not forget his high calling as a scientific man, and act for the general welfare of his patient and of society. He who simply pleases his patient by attending to local troubles, and does nothing but satisfy the prejudices and ignorances of the public, either has not learned the greater truths which his art and science contain, or is simply converting a noble profession into a trade. If the history of particular minds be identical with the history of the race, we shall find the mass of the public is in accord with the least scientific in our Profession. A layman recommends a remedy for a symptom, and offers his friends a medicine for the spasms or a pill for the liver complaint, and so on. All quacks knowingly and systematically pursue the same course; and the least educated in the Profession unwittingly follow a similar method. This is the explanation of such men doing large practices; their ignorance is a means towards success. In the history of the world we see savage nations attempting to exorcise particular pains, having of course no knowledge of their cause. At a later period, symptoms are treated; but in proportion to the

advances of medicine as a science, is the attempt at a wider generalisation being constantly made. If scientific treatment had been at the present day in any way perfected, how were it possible that, within a few years, bromide of potassium, carbolic acid, and chloral, should become in turn universal medicines? If any fact were required to prove the absence of scientific system in the treatment of disease, it would be the universal administration of chloral; every patient has some bodily uneasiness, or is sleepless, and thus presents symptoms suggesting its use. It is a powerful benumber; but benumbing the sensibilities and paralysing your patient is not curing his complaint. If a man be raving mad, and you knock him down and stun him, he will be quiet, and you may praise highly the dose which you have given him. The practice might thus be developed into a valuable therapeutic agent, and a trained boxer might give blows on the head of different degrees of force according to the strength of the dose ordered by the prescriber. The method would hold rank with the universal administration of chloral, and, in the hands of an expert, might perhaps be more safe.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 4, 1872.

THE ARMY REPORT.

We have received a copy of this great Blue-Book, which has just been issued, and is the report for 1870, although Dr. Parkes's report on Hygiene, to which we always turn at once, is for 1871. As usual, it is full of information put in the most interesting form. There are also other able papers, to which we shall return. Here we can only mention the cases, as follows:—

1. Case of transplanting of small pieces of skin to a large ulcer. By Surgeon Wolseley, 5th Fusiliers. 2. Tincture of Aconite in Pneumonia. By Surgeon Wolseley, 5th Fusiliers. 3. Case of Syphilitic Herpes. By Staff Assistant-Surgeon W. Curran. 4. Two cases of Varicocele treated by Vidal's operation. By Surgeon Porter, 97th Regiment. 5. Two cases of Hypospadiac Fissure, treated by Urethro-plasty. By Surgeon Porter, 97th Regiment. 6. Case of penetration of thoracic cavity

with wound of the lung. By Assistant Surgeon J. R. Murray, M.D., Royal Horse Artillery. 7. Case of Scrofulous Abscess in the walls of the left ventricle of the heart. By Surgeon Longhurst, M.D., 60th Rifles. 8. Aneurism of left Femoral Artery, ligature of External Iliac. By Assistant Surgeon Clapp, 54th Regiment. 9. Case of Thrombosis, occlusion of right Popliteal Artery and Amputation. By Staff Assistant-Surgeon Batho. 10. Case of supposed ocular disease. By Deputy Inspector-General Longmore, C.B. 11. Case of Development of Larvæ in the nasal passages. By Staff Assistant-Surgeon W. K. Stewart, M.D.

The total admissions to hospital for sickness were slightly higher than in 1869, but less than the average of the last ten years in the proportion of 1,095 to 1,129 per 1,000 of mean strength. The increase was chiefly in China, Japan, and India. The ratio of mortality was much lower than in 1869, and, moreover, was 2.47 per 1,000 below the average of the last ten years, an improvement being observable in India, Bermuda, Ceylon, and the Straits Settlements. The invaliding has increased of late. The mean daily sick shows a decrease of 5 per 1,000 in comparison with the average of the last decennium. Among the colonial corps there has been a marked increase in the sickness and mortality in Ceylon and Labuan, due to the unhealthy state of the detachment in the latter island. In Western Africa the ratio of mortality was less than half that of the preceding year. In China the admissions to hospital have been on the increase of late.

The recruiting returns for the twelvemonth refer to a total of 38,408 men examined for admission to the army. Of these 11,827 were rejected on primary and 1,108 on secondary inspection—12,935 in all, and giving a ratio of 336.7 per 1,000 rejections. Including both primary and secondary inspections, there was a reduction of 30 per 1,000 in the rejection of recruits examined by army Medical officers in the first instance, and 65 per 1,000 in those inspected by civilian Medical men, making a reduction in the rejections upon the total inspected of 33 per 1,000 on a comparison with the results of the previous year. But there was still a disproportion between the rejection of recruits at secondary inspections by army Medical officers and civilians, in the proportion of 16 to 116 per 1,000. England supplied 220, Scotland 66, Ireland 108.6, and the colonies, &c., 5.4 out of every 1,000 of the recruits.

The average strength of European troops in India was 55,380; the admissions to hospital were 89,898; the deaths 1,266; or in the ratios of 1,623 admissions and 22.86 deaths per 1,000 of mean strength, the former slightly above, but the latter 14 per 1,000 under the ratio of the former year. The 1st battalion of the 21st Regiment, which was decimated by fever and being sent to Bangalore, is not taken into account in the above calculation. At Peshawur fever prevailed. The admissions there were 1,898 per 1,000 of mean strength amongst the horse artillery, 1,705 the foot artillery, and 2,369 in the infantry. Inspector-General Muir, C.B., states in his report that the government "refused to sanction the issue of an extra blanket to the troops at Peshawur," though this step was "strongly recommended from the conviction that the repeated attacks of fever, to which the men were in the great majority of cases subject, arose from the sudden reduction of temperature after sunset, against which their regulated allowance of bedding (the same as in the plains of Bengal) did not furnish adequate protection." About 7,000 men

and families were located in the hills, and the numbers, it is satisfactory to learn, will be increased year by year. Dr. Muir recommends the still further reduction of the garrison of Peshawur, and he adds, "It is still much to be regretted that military necessity should demand such a sacrifice of health and life as service in that deadly valley year after year almost certainly entails." The history of the 1st battalion 21st Regiment affords a striking illustration of the necessity of locating our European troops in the hills away from the pestiferous plains as much as possible. Its average strength was 797, the admissions to hospital were 3,173, or 3,981 per 1,000 of mean strength, nearly in the proportion of 4 to every man serving. Besides, 171 men, or 214 per 1,000 strength, were sent home invalided, and 18 died. On the whole, however, the reports about India are to be regarded as satisfactory.

THE SUPPLY OF DRUGS TO WORKHOUSES.

A VALUABLE report has just been issued by F. W. Rowsell, Esq., Superintendent of Contracts to the Admiralty, relative to the system of supplying goods to the several workhouses of London; and we extract from the report information which will be alike interesting to chemists and druggists, the Profession, and the public. A series of questions were asked the authorities of the several unions, which elicited the fact that, generally speaking, the medicines and drugs supplied for the use of the inmates are obtained from excellent sources—viz., from some first-rate drug-dealer in London whose name and standing are sufficient guarantees for quality. There are, however, it is stated, a few exceptions, in which it would appear that local considerations prevail, and that the guardians are more desirous to provide for the "good of the parish" than for the quality of the drugs, when arranging for the dispensary supplies. Mr. Rowsell states, however, with reference to this matter, that he does not intend to insinuate that the local chemists and druggists do not supply drugs, &c., of good quality; but that "their position is not such as to make it vehemently improbable that they should sell some inferior articles; and I have reason to know in some instances that medicines thus supplied have not given satisfaction to the Medical officers." It is certainly of the utmost importance that Poor-law guardians should adopt every means to ensure the perfect good quality of their drugs, and therefore the remark of Mr. Rowsell, which we have just quoted, cannot be considered as altogether satisfactory. He further writes:—"In providing medicine for the navy it has been found desirable to deal only with first-rate houses, as most of the boards of guardians do, and to revise prices quarterly by the light of published price currents. It does not appear that this revision takes place at all the workhouses who deal with the best firms. It certainly should do so, as the price of certain drugs—*e. g.*, opium preparations, varies according to markets within a range of 35 per cent. Occasional competition even amongst the best houses is a desirable thing, so as to prevent a contract rusting, and to keep prices in check." We also learn the peculiar fact that at some unions it has been discovered that the Medical supply arrangements have been unaltered for fifteen to twenty years. Mr. Rowsell also states that surgical appliances seem to be had in quite small quantities, but from

good sources; and he points out that at some of the unions, as well as at certain hospitals, Tarragona wine is used instead of port for medicinal purposes.

The *sequitur* of Mr. Rowsell's report would appear to be that in his opinion, boards of guardians are doing everything that can be expected of them towards securing a supply of pure drugs if they contract by the year with "some first-rate drug dealer in London whose name and standing are sufficient guarantees for quality," and he further insinuates that local provincial druggists are more likely to be tempted to trade rogueries than their great metropolitan competitors. The experience of the Irish Poor-law Commissioners, frequently referred to in our columns, leads to a directly contrary conclusion, for it has shown that the name and standing of the largest Irish drug houses are no guarantee whatever for the quality of their supplies, and, in fact, the Boards of Guardians are quite as likely to receive honest dealing from the local druggist as from the largest dealers.

If Mr. Rowsell has no more bitter condemnation to express of the workhouse drug system, London sick paupers must be very happily situated comparatively to their Irish co-miserables.

We can inform him that in Ireland such an element as competition either in price or quality of workhouse drugs never penetrates the heads of guardians. Medicines are supplied for quarter centuries by the same firm, no other seller having, practically, any opportunity of competing. The drugs supplied may be purity itself, or they may be roguish rubbish, they may be honest in price, or grossly and preposterously exorbitant, for all the guardians know about it, and, to put the *status in quo* in a nutshell, both the tenders for contract and the prices for supplies have been many times shown to be grossly dishonest.

We dissent therefore, *toto caelo*, from Mr. Rowsell's idea that the poor ought to be left, as regards the efficiency of their medicines in sickness, to the tender mercies of drug dealers, large or small. The price and quality of drugs, as well as the condition in which they are kept at the dispensaries, ought to be judged by the verdict of skilled pharmacists, and the present system which leaves their purchase between bucolic guardians and greedy traders is too preposterous for discussion or comment.

THE REWARD OF VIRTUE.

As a consistent and persevering antagonist of flunkeyism—whether its origin be a prospective view of favours to come, a grateful recollection of benefits received, or a pusillanimous indisposition to say no to a demand for a subscription—the MEDICAL PRESS AND CIRCULAR cannot deny itself the pleasure of reprinting the following lately spoken words of the Earl of Essex: "In my opinion," says his lordship, "the practice so common of late years (to the extent of becoming a nuisance) of getting up a testimonial to any one, simply because he has conducted himself decently (not always the case) and has done his duty, is strongly to be deprecated, as leading to the inference that the doing of one's duty is of such rare occurrence that it requires a reward." The Earl of Essex might cogently have added to his statement that which every one knows, that it is never or rarely that a testimonial falls to the lot of a man who truly and honestly, "without fear, favour, affection, or

envy," does his duty; and the observation applies with especial force to our own Profession, for we know that Medical duties don't usually lie amongst those who can afford subscriptions to testimonials. Not at all! It is the Mac Sycophant who spends his life "booing" and leering, or the subordinate who humbly doffs his cap and "sirs" his superior when he meets him, who secures the salver and teapot.

Does any reader wish a decoration for his sideboard? Let him be "all things to all men"—blind when sight is inconvenient, deaf when hearing is out of place, of a leathery conscience, and without personal pride. Let him draw his social line tight and hard, snub all below it and toady all above, and in a surprisingly short time he will unfailingly enjoy the emblematic tea-things. Perhaps, after all, the esteem and respect of men who are incapable of selfish dodgery is of more sterling value than the teapot. Let people lay to heart Lord Essex's gentle reproof and be satisfied with the esteem which follows the performance of public or private duties. It is better and more lasting than yards of parchment and much beef and brass bands.

Notes on Current Topics.

Extrusion of the Gravid Uterus.

A CASE of extrusion of the gravid uterus is related in the *Det. Pharmacy*, as occurring in the practice of Dr. H. Fisher, and reported to the *Richmond and Louisville Medical Journal*. The os uteri being rigid and undilated, the doctor applied extract of belladonna, and states that he witnessed the dilating effect of the drug with his own eyes. Delivery was accomplished in four hours.

Oyl of Whelps.

AMBROSE PARC, born 1509, died 1590, says that he obtained the secret of preparing this *oyl* from a chirurgien of Turin, who, he observes, "presently wished me to provide two whelps, one pound of earthworms, two pounds of oil of lilies, six ounces of Venice turpentine, and one ounce of aqua vitæ. In my presence he boiled the whelps put alive into that oil until the flesh came from the bones; then presently he put in the worms, which he had first killed in white wine that they might be so cleaned from the earthy dress with which they are usually replete, and then he boiled them in the same oil so long till they became dry and had spent all their *juyce* therein; then he strained it through a towel without much pressing, and added the turpentine to it, and, lastly, the *cau de vie*."—*Fraser's Magazine*, March, 1855.

The late Mr. Poland.

GUY'S HOSPITAL loses the services of a skillful surgeon in the death of Mr. Poland, at the age of 52. At an early age he carried off the Triennial Prize of the College of Surgeons, and later he obtained the Fothergillian Medal, and in 1857 took the Jacksonian Prize for his essay on "Gunshot Wounds." As a lecturer he was much admired by the students of Guy's, and he was always remarkable for his sound and careful treatment, while he was a good operator. He had also been attached

to the Ophthalmic Hospital in Moorfields. Mr. Durham, the Senior Assistant-Surgeon, will, no doubt, succeed to the Surgeoncy of Guy's, and there will be a vacancy for an Assistant-Surgeon.

Defeat of a Board of Guardians.

NEXT quarter day the Workhouse of the West Ward District of the Penrith Union will be closed, the guardians not having complied with the requisitions made upon it by the Inspector of the Local Government Board. We expressed an opinion on this matter some time since.

Recovery of Fees for Dispensing by a Surgeon.

At the Sheffield County Court the Judge (T. Ellison, Esq.) has delivered a decision of considerable importance to Medical men. A surgeon in the town had entered about forty cases, and when the first, which was to recover the sum of 12s., was called on, his Honour asked him whether he was a surgeon or an apothecary, or both. The plaintiff replied that he was a surgeon only. His Honour then asked him whether he claimed the 12s. for surgical operations or for medicine. The plaintiff replied that the claim was for medicine, and not for surgical assistance. His Honour told him that he had no qualification as an apothecary to supply medicines, and the Act of Parliament said he could only sue according to his qualification. He held the qualification of a surgeon, and he could sue for nothing but what came within his surgical practice. The plaintiff said if that were so he would withdraw the case. In going through his list of plaints he withdrew all those for medicine supplied; and where the plaint was for surgical assistance and for medicines, he had to abandon the latter. Another Medical practitioner was in court who only held a diploma as an apothecary, but in his case no questions were asked, and he was allowed to prove his claims.

With sublime respect for the County Court Judge, we suspect this decision is very bad law and worse equity. We believe that any person registered under the Medical Act may sue and recover for fees for the discharge of any duty contemplated by that Act. The last paragraph in the foregoing narrative proves that our view is correct, because, if not, the apothecary would enjoy privileges as a Medical practitioner, which were denied to the physician or surgeon. An appeal would probably reverse the decision.

Preventible Small-pox Mortality in Ireland.

THE Rev. Professor Haughton, in his address in the Public Health Section of the British Medical Association, gave utterance to the following protest and appeal, which—convincing by its simplicity, and eloquent in its phrasing—deserves to be published in every paper in the three kingdoms. He said:—

"I am able to show, I believe conclusively, that unfortunate Ireland is now suffering, has suffered, and probably will suffer, more than her fair share of the epidemic of small-pox. In the case of cholera, I have shown that Liverpool, Dublin, and other towns, have suffered exactly in proportion to their different populations; and therefore, with regard to this disease, Ireland has no reason to complain, as compared with her neighbours. The number of deaths in Liverpool from small-pox, where the plague has now

ceased, was 2,093. The calculation of the number of persons who ought to die in Dublin from the epidemic was 1,236, on the supposition that it was equally protected by previous vaccination with Liverpool. The result is, however, far otherwise; for, according to the statistics of Dr. Burke, up to Friday last, 1,581 persons had died in Dublin, showing an excess of 325 preventible deaths. I believe finally that the number will be increased to 500 or 600. I stand here to ask for the sympathy of my brother Medical men in an appeal against the injustice with which the Irish people have been treated.

"Now let us look to the case of Cork. While much of the pestilence has passed away from other cities, it has hovered like a black cloud over the city of Cork, and the poor people are dying in numbers, the mere enumeration of the figures of which will convey but a poor idea. You may gather an idea by supposing that, while the pestilence was raging in London, the number of deaths amounted to 1,500 a week. The poor people of Cork have perished in the ratio of 23 per 1,000 a week from small-pox for thirteen weeks. I wish I could think no one was to blame for this. The poor sufferers themselves blame no one. They are attended by their priests, and with their last words express their kindly feeling and gratitude to their doctors and nurses, proclaiming their deaths to be 'the will of God.' That is a natural and becoming feeling in the poor sufferers; but we know better, and we know that most of those deaths might have been prevented. I have a right to present this as a solemn grievance. In the estimates for the present year, £10,050 was voted for the National Vaccination Institution of England; in addition to which, nearly as much more has been paid out of the public funds in payment for the services rendered by Medical men in vaccination. Thus nearly £20,000 has been properly spent in providing the people of England with gratuitous vaccination. In Ireland, only £400 per year is expended on the same object. It is a mystery to me how much good has been done with this amount, and it is a miracle to me how it has been made to go so far, for with that amount we have had to send lymph to the Poor-law guardians. Now is this justice to Ireland? Then lymph is given in England, but it is sold in Ireland; and, when we apply for good lymph, we are told we can have it by paying for it, which is like giving a hungry dog a joint off his own tail for dinner. I appeal to all fair-minded educated Englishmen to help us to get this grievance removed, for we may talk in Ireland until the day of judgment without getting the aid we seek. I appeal also to the public press to help us to get this justice, for which we have been asking in vain for years. In 1852, we made the most humble application which could be conceived—such an one as only negroes and Irishmen could make—to get £600 more, raising the grant to £1,000, which, it was calculated, by great economy and labour on the part of the officers of the Cow-pox Institution, would furnish lymph to vaccinate the whole population of Ireland; but it was refused by the Poor-law Commissioners, who were themselves a paid board. They sent the people to live in fools' paradise some years ago; and the officials of the Board published a statement, couched in the language of the stable, to the effect that the small-pox was 'stamped out' like the cattle plague—language which, in the lips of paid officials, was adding blasphemy to insult."

To Irishmen all this is well known to be true, though not new. We have ourselves repeatedly inveighed against the miserable parsimony of the Irish grant for the collection and distribution of lymph.

We earnestly trust that Dr. Haughton's burning words may achieve the result which he desires. If they should cause a revolution in the present lymph service of Ireland, we have reason to hope that reform may extend to the present administration of the service by the Dublin Cow-pox Institution.

In that corporation, conclave, or clique a dogged and obstinate secrecy as to its doings, its constitution, and its expenditure has been always maintained, which has produced the inevitable result of an angry suspicion of its proceedings, on the part of the Profession and the public. For that reason alone a reform must take place sooner or later, and we earnestly trust whatever change in the administrative system the Government may think essential will carry with it the realisation of Dr. Haughton's and our own hopes.

Portuguese Military Medicine.

We have already given, from the original Portuguese documents, some information as to recent reforms in the Medical Corps, and in the Sanitary Service of the Army in Portugal. We now add a translation of some of the other orders:—

HOSPITALS.

ART. 43.—In time of peace the hospitals are permanent and regimental, in time of war they will be permanent and temporary.

ART. 44.—There will be established a permanent hospital in Lisbon and one in Porto. The direction of these hospitals will be entrusted to the two Brigade Surgeons mentioned in Art. 6.

§ I. When by any unforeseen result, a large body of men may be required to remain permanently at any other given point, the same regulations will be adopted as for the hospitals of Lisbon and Porto.

ART. 45.—In each permanent military hospital there will be a board composed of a director, who will act as president, and of two staff-surgeons, the senior in the hospital, the junior acting as secretary.

ART. 46.—The board will be entrusted with the administration of the funds, which will be received into a chest with three keys, one for each member of the board.

§ I. The three keepers will be each responsible and *in solidum* for all sums entered, as also for all sums paid out without a document proving its lawful application.

ART. 47.—The hospital accounts will be for the present kept according to the regulations of 30th June, 1825.

ART. 48.—Each permanent military hospital will have a chaplain, who must reside in the establishment. Besides his salary he will receive a gratification of 4,800 reis per month (= £1 1s. 2d.).

ART. 49.—The personnel or staff of inferior *employés* in the permanent military hospitals, is composed of first and second amanuenses, buyers and keepers, nurses, assistant-nurses, porters, cooks, assistant cooks, soldier messengers, and servants.

ART. 50.—The regimental hospitals of "Elvas" and "Chaves" and the other united regimental hospitals which may have to be organised, will have a staff of *employés* from the health company, composed of amanuenses, buyers, keepers, nurses, cooks, and servants.

ART. 51.—The temporary hospitals in time of war will be established at the most convenient stations for the prompt and easy reception of the sick or wounded from the corps in operation.

§ I. The organisation of the temporary hospitals will be the same in all that is applicable to the permanent hospitals.

ART. 52.—When a detachment has to remain in any place where no military hospital exists and it would be impossible to establish a regimental hospital, the Staff-Surgeon in combination with his commander will establish a regimental infirmary, using the ambulance linen and clothing. In this infirmary will be treated all cases of less importance, forwarding any others to the civil hospital.

THE Emperor of Germany has nearly recovered from the injury to his foot, and his general health is now excellent.

THE fifth annual general meeting of the Association of Certifying Medical Officers of Great Britain and Ireland will be held at the Clifton Down Hotel, Clifton, Bristol, on Friday, the 13th of September, at 2 p. m. Dr. Adlidge, the president, will deliver the annual address. The secretary will be happy to give every information respecting the objects of the Society to any certifying Medical officer who may wish to join the Association.

IN the *San Francisco Western Lancet* of July, Dr. Bard narrates a case of tetanus treated to recovery by bromide of potassium. He gave thirty grains every hour until four doses had been taken, and then lessened both the frequency of administration and the quantity. The patient took altogether three ounces of the bromide.

Scraps from the Editor's Table.

ANCIENT IRISH PHYSICIANS.

IN the fourth edition of the Rev. Father Meehan's work, "The Rise and Fall of the Irish Franciscan Monasteries," is contained a most interesting note on the Ancient Irish Physicians. Father Meehan says:—"The ancient Irish chieftains were at all times the most worshipful patrons of the professors of the healing art, and zealous promoters of Medical science. We have ample evidence to prove that hospitals and leper-houses were established in Ireland at a very early period, in connection with the monastic institutions, and that the inmates of the latter here, as well as in Italy, exercised the calling of surgeons and physicians for many ages, till the Canon Law forbade them to continue its practice."

After referring to the old treatises on medicine, written by Irish physicians in the Gaelic language, some of which are now preserved in the Royal Irish Academy and in the British Museum, Father Meehan says:—

"The names of many of the hereditary physicians have been faithfully transmitted to our times, and it may gratify some of our modern Medical men to know who they were, and what amount of compensation they received from their lords and patrons. The O'Connors were physicians to the Maguires of Fermanagh for fully two centuries, that is, from 1320 till 1504, when Thomas O'Connors, the last hereditary practitioner, wrote a tract on the 'Nature and Cure of the different Diseases incident to the Human Frame.' The O'Lees were for many centuries physicians to the O'Flahertys of West Connaught, and one of that learned family, as early as the fifteenth century, produced a most complete course of medicine, written in Latin and Irish. So wonderful were the cures performed by this Murrough O'Lee, that the natives of West Connaught imagined that he had received all his knowledge from the genii of the enchanted island of O'Brazil! The O'Hickeys were physicians to the O'Briens of Thomond, and other heads of septs in Munster. They possessed a copy of the 'Lily of Medicine,' the original of which was written in 1303; and a member of the same family (Nicholas O'Hickey) translated the 'Rose,' a manual of medicine, regarded as the most celebrated of its time, from Latin into Irish. This 'Rosa Anglica' was the work of Gaddesden, who flourished in 1305, and O'Hickey's Latin version was made in 1400. To these we may add the O'Callanans of Cork, hereditary physicians to the

MacCarthy's of Carbery; the O'Donlevys, of Tyrconnell, physicians to the princely house of O'Donel; the O'Mellans and O'Quinns, all of whom were famed in their day as successful practitioners of the healing art. The works which they wrote were numerous enough to attest their zeal for the advancement of Medical science, and we have to deplore the removal of many of them from this country, at a period within our own memory, when a true spirit of nationality might have secured such valuable remains for the Irish Academy or some of our public libraries. The O'Mearas, who for a considerable time were hereditary physicians to the Butlers of Ormond, flourished in the sixteenth and seventeenth centuries, and were the first of our native physicians who published Medical works in Latin. Dermot O'Meara has left us a book entitled 'Pathologia Hereditaria Generalis,' which was printed in Dublin, in 1619; and Ware says that the same author wrote a tract styled 'Hippocraticam Febrium Aetiology et Prognosis,' which, we believe, has not been published. This Dermot O'Meara was a very learned classical scholar, and wrote a very admirable poem in Latin hexameters, to celebrate the victories of the Butlers over the ill-fated house of the great Earl of Desmond. His son Edmond and his grandson William, were also physicians, and the former wrote a work on fever against the theories of Willis, entitled 'Examen Diatribe Thomae Willisii, &c.,' London, 1665.'

CHLORALUM.

THE *Pharmaceutical Journal* of last Saturday says:—"We know that chloralium has been authorised by the President of the Board of Trade, and has now therefore to be carried in the medicine chests of all merchant ships (to the exclusion of Sir Wm. Burnett's solution of chloride of zinc), although no directions of any sort or kind are given as to its use in the 'Ship Captain's Medical Guide,' authorised by the Board. We have indeed heard it stated by public officers and others interested in sanitary matters, that they have vainly endeavoured to find out the merits of this so-called deodorizer, disinfectant, and antiseptic. Medical men and professional chiefs of public departments tell us that they know little or nothing about it. But it is most humiliating to those engaged in the promotion of sanitary science, to Medical men, and to all occupied in work connected with the prevention of disease, that no one even now can say or has said *ex cathedra* whether this preparation is good, bad, or indifferent. There are things that are true, and things that are new. We want to know if the new thing in this case is a true thing, and most naturally appeal to the Medical Department of the Local Government Board, or—if such an officer exist—to the Medical adviser of the Board of Trade."

The last issue of the MEDICAL PRESS AND CIRCULAR, page 184, contains an article of Professor Fleck, of Dresden, which says very decidedly *ex cathedra*, that the preparation is very indifferent. He sums up his conclusions as follows:—"The real value of the contents of a bottle of chloralium, which is sold at 15 sgr. (1s. 6d.), is not to be computed as above 2 sgr. (rather more than two pence). The value of the chloralium powder, which is sold in tin canisters at 5 sgr. (6d.), cannot be placed higher than 1 sgr. (rather more than one penny), seeing that it is but dried sediment. The chloralium wadding, which is sold for 20 sgr. (2s.) is only worth $\frac{1}{2}$ sgr. (rather more than a half-penny), at the utmost. A solution of 10 g. of sulphate of alumina in 1 lb. of spring water would be a perfect substitute for the above preparations, all the component parts of which, excepting the chloride of aluminium, are to be regarded as impurities or poisons, and this solution would not exceed 1 sgr. in value (rather more than one penny)."

ON COUNTER-IRRITATION.

DR. ANDREW H. SMITH, of New York, published recently in the *New York Medical Journal*, April, 1872, a paper on the Circulation, with special reference to counter-irritation, a reprint of which has come into our hands.

After advertizing to the delicacy of the mechanism by which each tissue or organ receives exactly the amount of blood required not only for its nutrition, but also for its function, the supply varying exactly with the varying activity, he proceeds to show that the regulating power by which this is effected resides in the arteries and veins, the capillaries being destitute of contractile tissue.

This regulating power is of extreme importance, since the amount of blood required in any given part is constantly changing, and depends upon the activity of the part for the time being. Whenever an organ, before at rest, is brought into action, a demand is occasioned for an increased supply of blood, and the vessels leading to the part dilate to the extent required.

Dr. S. regards all function, with the exception of that of the organs of special sense, as the result of the chemico-vital reaction between the tissue of the acting organ and the blood which courses through its capillaries; and the nervous system as having no other office in this regard than that of regulating the supply of the nutritive fluid. Hence, blood being an essential factor, and the quantity in the system being pretty nearly constant, it follows that a number of activities cannot be carried on simultaneously for want of a sufficient supply of this necessary fluid. This conclusion, arrived at theoretically, is sustained by observation. We find that a proper performance of the digestive function is incompatible with great muscular activity; that the brain and the muscles cannot put forth at the same time the maximum of effort; and, when a full meal has created a demand for a largely-increased circulation through the capillaries of the stomach and intestines, the brain is rendered anæmic, and drowsiness results. No two of the great emunctories of the system can be stimulated to excessive action at the same time. A diuretic and a diaphoretic will not act well together, nor will either act during the operation of a cathartic. These well-known facts are usually explained by assuming that the nerve-force is the primary element in all these activities, and that it is a constant quantity, and cannot be expended in one direction without being proportionally deficient in others.

Under certain conditions of disease it may become desirable to attempt to modify, artificially, the nutrition or the function of some given organ or part.

Among the means resorted to for this purpose counter-irritation holds a prominent place.

The *modus operandi* has been the subject of endless discussion, which still leaves us so much in the dark that Headland sums up our knowledge upon the subject in these words: "It appears that, as a consequence of the action of counter-irritants, the attention of the nervous system may be drawn off from the morbid process going on at some other part of the body;" and again, "The term 'counter-irritation' is employed to express this action, the nature of it being but ill understood. A powerful impression on any surface of the body, external or internal, seems to be capable of arresting and diverting, as it were, the attention of the system, and thus, for a time, of checking a morbid process."—(On the "Action of Medicines," pp. 67, 97). These statements are scarcely more intelligible and scientific than the famous aphorism that "Nature abhors a vacuum." They express, however, as clearly as it is possible to express anything so intangible, the idea intended to be conveyed by the term "*substitution*," the substitution of one morbid process for another by a sort of hood-winking of the system. But "*substitution*" has to share the honours with "*revulsion*" or "*derivation*," terms employed to express the accumulation of an excess of blood in the place irritated, which excess is supposed to be drawn, wholly or in part, from the diseased locality. This idea, however, is met by the

objection that the extra quantity of blood under a sinapism, for example, is so insignificant that its abstraction could have no appreciable effect upon a distant organ, with which there may be no direct vascular connection. This objection is valid from the stand-point from which it is taken.

Except in cases in which the pain results from a mechanical cause capable of being removed by muscular action excited by reflex irritation, he holds that all the benefits resulting from counter-irritation are obtained directly or indirectly through the circulation. In the first place, he considers all pain (excluding that from extraneous irritation) as proceeding from imperfect nutrition, even though there be no evidence of inflammation. This is only in accordance with the proposition that there can be no derangement of function without change of structure. Now, if the morbid condition be one dependent upon the quantity (not quality) of the blood supplied to the part which is the seat of pain, then, in his view, counter-irritation may be of service, but not otherwise.

In the case of inflammatory action, the agency of the vessels will be admitted with less argument. But the difficulty in either case has been that already stated—that the *apparent* change in the circulation is too trivial to be credited with the results observed. He reserves the word "*apparent*," and on this reservation his entire argument rests. In all the discussions upon this subject, up to the present time, attention has been confined to the excess of blood contained in the irritated part. If, for example, the entire mass of tissue to which the irritation extends could be cut out at one stroke, and the blood expressed from it, the excess of this blood over what would naturally be contained in the same quantity of tissue, would represent what has been considered as the sum total of the change supposed to have been effected in the circulation at that point. Or, if the irritation was supposed to be reflected upon some other point, the result there was regarded in the same light.

It is here that he thinks a mistake has been made. The question is not, how much blood the vessels of the irritated part will hold, but how much they will transmit in a given time. This becomes evident when we consider that a given amount of blood passes through the capillaries of the body in each unit of time, and is transferred from the arterial to the venous side of the circulation, and that the quantity passing through any one part must affect that passing through the remainder of the body, since the latter must be the exact complement of the former. Thus, if in a given time four pounds of blood pass through the capillaries of the entire body, and of this one pound passes through the capillaries of the arms, it follows that three pounds must pass through the remainder of the capillary system. Now, if we plunge the arms into hot water, and dilate the vessels so that an additional half-pound passes through them, the remaining vessels will transmit but two and a half pounds, and the tissues which they supply will be deprived for the time of one-sixth of their nourishment. It will be perceived that this is a matter entirely apart from the quantity of blood which might be contained in the arms if severed from the body.

The resistance to the passage of a fluid through a tube being derived chiefly from the friction against the sides, it will increase in proportion to the ratio of the circumference to the area of the section. Now, the circumference of a circle increases directly as the diameter, while the area increases as the square of the diameter. The friction is obtained by dividing the circumference by the area, and therefore decreases directly as the diameter increases, as is shown by the following formula:—

Diam.	Circum.	Area.	Friction.
			b.
a.	b.	c.	—
			c.
			2 b. b.
2 a.	2 b.	4 c.	— = —
			4 c. 2 c.

From which it appears that doubling the diameter of a tube quadruples its area, and at the same time divides the friction by two.

But, great as is this disparity, it is immensely increased in practice, especially when the tube is of very small calibre and tortuous or branching. The following experiments serve to show how slight an increase in the diameter of a tube will suffice to augment its carrying power enormously :

EXPERIMENT I.—A glass tube ten inches in length, and having an inside diameter of .052 inch, gave passage to six drachms of water in 122 seconds. Another tube, of the same length, and under the same conditions, but having a diameter of .08 inch transmitted the same quantity of water in twenty seconds.

In this case the addition of one-half to the diameter of the tube allowed the passage of six times the quantity of fluid.

EXPERIMENT II.—The same tubes were used as in the last experiment, and all the conditions were the same, except that defibrinated bullock's blood was employed instead of water. The blood was previously strained through very fine linen. The smaller tube required 1,440 seconds to transmit six drachms ; while the larger tube gave passage to the same quantity in 142 seconds.

In applying the results obtained from these experiments to the question of counter-irritation, we find that certain stimuli applied to the skin act in such a way upon the vaso-motor nerves as to cause a relaxation of the terminal arteries, and a dilatation of the capillaries. If the irritation be considerable, the surface assumes a bright-scarlet hue, in the place of its previous flesh colour. Such a change in the colour implies a very considerable increase in the diameter of the capillaries.

EXPERIMENT III.—A tall, narrow vessel was partly filled with water, at the temperature of 120° Fabr., and the naked forearm thrust into it to near the elbow, the arm resting upon a support. Enough water was then added to exactly fill the vessel. Within half a minute the vessel began slowly to overflow, and continued to do so for several minutes. At the conclusion of the experiment, it was found that half an inch of water had been displaced. This, of course, represents a corresponding increase of volume in the arm, and, as this could take place only by an increase of the quantity of blood in it, it follows that half of a cubic inch of blood was added to the amount present before the observation. This represents the increase in the *area* of the capillaries, and measures what has heretofore been considered the extent of the effect produced upon the circulation.

But, in view of the results observed in Experiment II., it will be seen that this can by no means be taken as a criterion of the effect obtained, the increase in the carrying power of the vessels being so greatly in excess of the increase in their area.

Of course this excess in the circulation in one part implies a corresponding deficiency in some other part. Were the blood-vessels passive tubes, the deficiency would at once be distributed over the whole body ; but the larger arterial trunks, at a distance from the point of irritation, but between it and the heart, contract in proportion as the pressure upon them is lessened, and thus the effect is confined within a limited area, and the excess is at the expense of neighbouring vessels.

(To be continued.)

Literature.

ELEMENTS OF CHEMISTRY (a).

THE value of "Miller's Elements of Chemistry" as

(a) "Elements of Chemistry." By Wm. Allen Miller, M.D., &c. Revised by Herbert McLeod, F.C.S. Part I. "Chemical Physics." 5th edition.

a work of instruction requires no more striking proof than the rapid issue of different editions which have from time to time been brought forward. The principal additions to this volume are in solar chemistry and optical analysis. The descriptions of the late investigations of Messrs. Lockyer and Frankland and others are given very fully. Stokes' investigations, by-the-bye, as regards the absorption of the invisible rays by such substances as the vegetable alkaloids and the glucosides are given, and his spectra figured. Just as indigo and other coloured substances produce absorptive spectra of the visible rays, so strychnine, brucia, morphia, and papaverine produce absorptive spectra of the invisible rays which are highly characteristic of each compound, and frequently differ (according to Stokes) as they were examined in an acid or an alkaline fluid. This might be used practically in medico-legal investigations.

As regards the addition to the part devoted to the atomic theory, it savours too much of Dr. Frankland. However good and excellent it may be in its way, it is not Miller, nor is it thoroughly accepted by the chemical world, and, therefore, if introduced at all, so should also have been introduced the views, theories, and graphic notation of Kékulé, Naquet, and many others equally well known.

Obituary.

ALDERMAN JOHN MACKESY, M.D., J.P.

WITH feelings of the very deepest regret we have to record the death, at Buxton, whither he had gone for recreation last week, of Alderman John Mackesy, M.D., J.P., of the Mall, Waterford, in the 63rd year of his age. During a long and honourable career, Dr. Mackesy held a truly creditable public position in Waterford. In 1869 he filled the high office of mayor, and discharged its responsible duties to the infinite satisfaction of the corporation and the citizens over whom he worthily presided. Appointed to the magistracy at the close of his mayoralty, Alderman Mackesy brought to the bench the same *spirit* which guided him in the council. As a Medical man he occupied a very eminent position, and enjoyed a large and lucrative practice, whilst in private life he was distinguished for his truly affectionate disposition and the geniality of his social qualities. Immediately on the sad news reaching the city the corporation flags on the City Hall and Tower were hoisted half-mast, under charge of Serjeant-at-Mace Mahony, followed by the steamers and other shipping in the river, the business establishments along the quays putting up the usual signs of mourning. Alderman Mackesy leaves behind, besides his widow, who is sister to Mr. Justice Lawson, one son, Captain Mackesy, who holds a staff appointment in India, where he has seen considerable service, and one daughter, besides large connections amongst several of the most respectable local families.

Medical News.

The Military Secretary, India Office, presents his compliments to the Editor of the MEDICAL PRESS, and begs to enclose for publication a list of the Candidates for Her Majesty's Indian Medical Service who were successful at the Competitive Examination held at Burlington House on the 12th August, 1872. Thirty-two candidates competed for fifteen appointments as Assistant-Surgeons. All were reported qualified.

Prizes Awarded at the London Medical Schools.—Session, 1871-72. Guy's Hospital.—The Treasurer's Gold Medal for Medicine:—C. H. Golding Bird; the Treasurer's Gold Medal for Surgery:—G. H. Golding Bird. Third-year Students.—F. T. Paul, first prize, 40l.; R. C. Chicken, second prize, 35l.; R. S. Mutch, certificate; H. Williams, certificate; J. P. Bevan, certificate; A. W. Emms, certificate. Second-year Students.—H. Clarke, first prize, 35l.; C. E. Barnard, second prize, 30l.; C. Duran, third prize, 20l.; W. H. Lamb, certificate. First-year Students.—First prize not awarded; H. F. Lancaster, second prize, 25l.; J. Utting, third prize, 10l. 10s. Entrance Examination in Classics, &c.—F. C. Coley, first prize, 25l.; E. O. Giblin, second prize, 20l.; A. Finch, third prize, 15l.; D. Elcum, certificate; G. W. Baird, certificate; W. C. Kidd, certificate.—St. George's Hospital.—First Year Students.—Prize, W. A. Ellis; honorary certificate, Mr. Bull; hon. certificates in anatomy and physiology, Messrs. Blake, Cadge, and Henley. Second Year Students.—Prize, John E. Scatliff; hon. certificate in materia medica and chemistry, A. Scatliff; hon. certificate in anatomy and physiology, Mr. Spitta; certificate of proficiency in anatomy and physiology, G. Harper. Third Year Students.—Prize, William H. Bennett; hon. certificate, Mr. Goodchild; certificate of proficiency in medicine, J. H. M'Kinlay. The Treasurers' Prize.—W. H. Bennett. The Auckland Prize.—J. English. The Brodie Prize.—John Morgan. Sir Charles Clarke's Prize.—C. Douglas. The Thompson Medal.—No competitors.

Royal College of Physicians, London.—The following gentlemen have been elected by the council examiners for the ensuing year:—Anatomy and Physiology—Frederick W. Pavy, M.D.Lond., and John B. Sanderson, M.D.Edin. Chemistry, Materia Medica, and Practical Pharmacy—Alfred S. Taylor, M.D.Lond., and William H. Dickinson, M.D.Cantab. Medical Anatomy and the Principles and Practice of Medicine—Herbert Davies, M.D.Cantab., and George Johnson, M.D.Lond. Midwifery—John B. Hicks, M.D.Lond., and William S. Playfair, M.D.Edin. Surgical Anatomy and the Principles and Practice of Surgery—Campbell De Morgan, F.R.C.S., surgeon to the Middlesex Hospital, and George W. Callender, F.R.C.S., surgeon to St. Bartholomew's Hospital.

Correspondence.

RÖTHELN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Looking over old notes, I come across two cases of this rare hybrid affection, called, I think, also German measles and Morbillosa scarlatina. Both cases did well, and were on the whole mild cases of scarlatina, with a rubeoloid rash instead of the ordinary scarlet efflorescence of that zymotic. The diagnosis is difficult, particularly where history exists of scarlatinal infection, and when there appears the characteristic sore-throat yet not the temperature nor high pyrexia of scarlatina, a morbillous eruption, and yet although some catarrhal symptoms are present the perfect train of morbillous symptoms is not developed. One does not think of the disease so rarely met with, seldom noticed, and but unfrequently leard of. In one of the cases several herpiginous clusters appeared coincidentally with the other rash, which made me at first think of general acute herpes, a still rarer disease, which I once met with in England. No difficulty whatever about the treatment, saline and chlorate of potash. I remember reading some brief, but very interesting remarks on Röheln some time since, I think in the *Lancet*, and by Sir William Jenner, but though I have piles of old numbers of that journal now before me on the table I cannot find them. I have little doubt but cases of Röheln are still met with and remain unrecognized. I believe it is sometimes said to be epidemic.—Yours obediently,

FRANCIS E. CLARKE, M.B.

Lawrence Street, Drogheda,
August 29th, 1872.

P.S.—A letter received from my friend Mr. Allarton, the accomplished introducer of "Median Lithotomy," promises me reports of two pretty recent case, in which he performed, with great celerity and success, his own operation. If I get them I shall send them you. They will doubtless be of interest, more particularly now that Mr. Pemberton has brought the topic of "Allarton's Operation" on the *tapis* by alluding to it forcibly in his address to the British Medical Association.

SHARP PRACTICE IN VIENNA.

A VIENNA correspondent of the *Chicago Medical Examiner*, gives a warning about the private Medical courses there, which we are sorry to see needed. Such tricks are disgraceful. He says:—

There are quite a number of private courses, conducted on the evident principle of first squeezing all the money possible out of their victims, and then giving them just as little instruction in return therefore as possible, with the idea, apparently, of thus obliging them to take another course in order to complete the unfinished subject; very much on the same principle that a gambler, after having played once and lost, must try again in order to recover his loss, and then having lost a second time, he cannot, of course, give up without one more effort to win it all back.

I might mention here a single case in illustration. A certain young professor, the son of one of the best known leading members of the Vienna faculty, gives a private course of twelve lessons, one hour each, on auscultation and percussion, for which he charges the moderate sum of fifty guilders, or twenty-five dollars. One of his late victims, on venturing to mildly remonstrate with him on the rather meagre and unsatisfactory character of the instructions received, and the very sparse amount of material offered for practice and illustration, received the suggestive reply that in his next course he should take the class into another ward, where there was a much better supply of material, and that he should, therefore, be able to make it much more profitable and interesting. My friend *didn't bite*, however. Very few do, I think, a second time.

NOTICES TO CORRESPONDENTS.

THE Editor of the IRISH MEDICAL DIRECTORY will be glad to receive, and, if possible, to carry into effect in the forthcoming issue of the DIRECTORY, any suggestions for new matter, or emendations in the old. The Editor will add to the DIRECTORY any information which may appear to be interesting or useful to even a small section of the Profession in Ireland; and he solicits from the readers of the DIRECTORY their advice on the subject.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this request.

All communications intended for insertion must bear the name and address of the writer; not necessarily for publication, but as a voucher of good faith.

Rejected MS. will always be returned, if a request be received from the author, within one week after the article or letter has been declined.

SUBSCRIPTIONS IN THE UNITED STATES.—A correspondent has drawn our attention to the fact, that some of the houses in the United States are charging the enormous figure of 15 dollars per annum (more than £8) for supplying this Journal to different parts of the States. We beg, therefore, to state that we shall be happy to supply the same regularly post free per annum, if paid in advance, for considerably less than half this amount, viz., six and-a-half dollars (about £1 6s. 0d.), either direct from our offices in this country, or through our recognised agents in the United States.

TO OUR SUBSCRIBERS.—It having been suggested to us that it would be a matter of great convenience to Subscribers visiting the metropolis to know where they can give instructions for their letters to be addressed previous to leaving home, we have pleasure in informing them that the Publisher has consented to take charge of letters addressed to his care, and that he will place a desk at the disposal of Subscribers whose names are upon our lists, for short correspondence, where such accommodation is desired.

THE FOOD REPORTS.—The next Series of Chemical and Physiological articles upon the important subject of Food, will be devoted to Meat Extracts, Australian and other imported Preserved Meats. We trust this Series will be as useful to our readers in determining the relative value of food substances, and provoke as much interest generally as those which have already appeared. We shall be fully prepared to give the results of our investigations in the course of two or three weeks.

We quoted last week an editorial reclamation from the *Canada Lancet*, and now reprint a portion of it and our own observations thereon:—

"We take this opportunity of referring to the unkind treatment we have received from some Medical men who lay claim to respectability. These gentlemen are in the habit of taking the journal from the post office regularly, some of them for upwards of a year, and when the bill is presented they either repudiate it entirely, or invent some plausible excuse for not contributing their quota of the expense of publication. We care little for the loss thus sustained, but we regret to find such men in the Profession, and in one or two instances we felt disposed to give their names the benefit of a public announcement. Such conduct is not in keeping with the dignity of the Profession, and we believe it would have a salutary effect to hold such men forth in their true colours."

"*Mutato nomine de nobis fabula narratur.* We are compelled to make the humiliating admission, that the gratuitous patrons of Medical literature are not a special growth of the Canadian soil. We were last week favoured with a communication from such a one, who naively informed us, after the receipt by him of sixty-four consecutive numbers of our journal, that he thought it was sent to him for the year and quarter by 'some lecturer or other.'"

Two correspondents, who appear not to consider that their "withers are unwrung" by these remarks, favour us with post-card denunciations. They inform us that our Journal was not ordered, and they, therefore, conceive themselves entitled not to pay for it. Without joining issue on that point, respecting which our word is as good as theirs, we ask these gentlemen whether they would consider it honest and respectable if their milkman were (say, for argument sake, in error) to deliver a pint of milk daily at their houses, to take in the same daily for eighteen months, put it in their tea, and grow fat on it, and then tell the milkman that they thought he was making them a polite present, or that they "never ordered it." We assure them that the law differs in opinion from them, and were it otherwise, it would be necessary for every newspaper to keep for evidence the order of every subscriber on their list. He who, without repudiation, habitually and day to day, receives and makes use of goods - whether sent in error or not - is both legally and honourably liable to pay for them.

TINCTURE OF GELSEMIUM AS A SUBSTITUTE FOR QUININE.

To the Editor of the "Medical Press and Circular."

Sir, - I am delighted to see in your last number a notice of a very valuable medicine - Gelsemium - apparently new to Dr. Anderson.

Perhaps he and your readers generally may be glad to know that a very full description of the drug can be found in "New Remedies; their Pathogenetic Effects and Therapeutical Application," by Edwin M. Hale, M.D., published in London now many years ago. - I am, Sir, yours obediently,
J. N. BLAKE, M.R.C.S. Eng.

Taunton, August 30th, 1872.

THE INTRODUCTORIES IN THE LONDON MEDICAL SCHOOLS.—The addresses at the opening of the medical schools in London on the 1st proximo, will be delivered as follows:—At Guy's Hospital, by Pre-Smith, M.D. London; at St. George's, by Mr. Rouse, F.R.C.S.; at St. Thomas's, by Mr. Croft, F.R.C.S.; at University College, by Mr. Heath, F.R.C.S.; at Charing Cross, by J. Watt Black, M.D. Edin.; at St. Mary's, by Mr. Trehern Norton, F.R.C.S.; at the Middlesex, by W. Cayley, M.D. Lond.; and at the London Hospital, by Mr. Hutchinson, F.R.C.S.

DR. F. E. CLARKE will receive an early proof of "Practical Obstetrics; MEDICINE AND MEDICINE MEN—A MIDNIGHT ESSAY.—Under this heading we have in type a rather clever letter, but cannot send the author proof for correction, as we have mislaid his name and address. If our correspondent will kindly furnish the necessary information, the printers will forward slips per return of post.

APPOINTMENTS.

DICKINSON, E. H., M.A., M.B., Lecturer on Comparative Anatomy at the Liverpool Royal Infirmary.
FINLAY MURCHISON, M.B., C.M., Univ. Edin., Medical Officer for the parish of Harris, Inverness-shire.
FITZJOHN, R. IRWIN, M.B., L.R.C.S.I. and L.M., Medical Officer, &c., for the Scotstown dispensary district of the Monaghan Union.
HENSLEY, P. J., M.A., M.D. Cantab., F.R.C.P., Physician to the Royal Hospital for Diseases of the Chest, City Road.
PARKER, R., M.D., Demonstrator of Physiology at the Liverpool Royal Infirmary.
FRACY, W., M.R.C.S., House Physician at Bartholomew's Hospital.
WICKHAM, W., M.R.C.S., Medical Officer, &c., for the Tetbury District of the Tetbury Union, Gloucestershire.

VACANCIES.

Parish of St. George, London, W. Medical Officer of Health. Salary £350 per annum. (See advt.)

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.
The Heart and its Diseases. By J. Milner Fothergill, M.D. London: H. K. Lewis.

Observations in Myology. By G. M. Humphry, M.D. London: Macmillan & Co.

Original Communications.

THE MINERAL WATERS OF AMPHION.

BY DR. DE PASCALE.

AMPHION is situated in the department of Upper Savoy, on the south side of Leman, between Thonon and Evian, and at a short distance from this last place, to which it is united by the fine road of the Simplon, a lasting souvenir of the French rule.

It is situated in a fine park, about half a mile long, between the road and the lake, containing the springs, the bathing establishment, and three magnificent hotels, offering every desirable comfort to the bathers.

"It is difficult," says Dr. Mauget, "to see anything more peaceful, more retired, and more pastoral than the establishment of Amphion. It is a sweet retreat, a charming villa, the walls of which plunge in the lake, glassing themselves in its limpid waters. We proceed there at our choice by a wide and well-shaded road that omnibuses traverse six times a day, or still better by water, by means of a charming pleasure vessel. An English garden in the form of an amphitheatre turned towards the lake, well planted with trees and bushy groves, in a gentle inclination, with well arranged slopes, serves as an avenue to the establishment on the land side, and a pretty landing place lets the steam boats arrive by the lake as far as the foot of the wall of the house."

"A suitable 'table d'hôte,' a reading room, the cool shades of the garden, a terrace on the shores of the lake, spacious chambers, pleasure boats, the races at Evian, everything has been provided by the proprietor of the establishment to add to the charms that nature has afforded to this beautiful spot."

Every one knows that the topographical situation of a thermal station, and the quality of the air that we breathe there has an enormous influence on its therapeutic results. According to all these accounts, and as a summer station, Amphion leaves nothing to be desired. Situated in the 46 deg. 20 min. of north latitude and the

6 deg. 45 min. east longitude of the meridian of Greenwich, it belongs to the zone of the temperate climates. In summer the heat there is never excessive, for it is at the foot of a hill which shelters it from the south winds, and its atmosphere is constantly renewed by the breezes from the lake and the mountains of Jura. Besides, the magnificent trees of its park, the venerable forests of the hill, all in themselves giving shade and freshness, bring currents of ozonized oxygen, which purify the air, and in accelerating hematosis are of great assistance in all affections characterised by languor of the functions of circulation. We never breathe there this heavy, parched air, which by adding its depressing action to the yet more depressing action of certain waters more strongly impregnated with minerals, often puts invalids in a nervous state, which is most painful, and compromises or paralyzes the good effect of their treatment. We also believe that this admirable *ensemble* of hygienic conditions is well calculated to compensate for the advantages which certain carbonated sodaic waters have which are more strongly impregnated with minerals.

As distraction and exercise form an important part of the treatment by mineral waters, we will say that the environs of Amphion offer very varied and interesting excursions.

The tourists who wish to make the tour of the lake can take the steam boat and visit in turn Thonon, the capital of Chablais, Geneva, the Protestant Rome, Lausanne, and its old cathedral, the pretty town of Vevey, Chillon, the prison of Bonnavard. Clarens, Montreux, the rocks and grotto of Meilleric, or St. Preux.

To those who wish to have an idea of the vegetation of Savoy, I recommend the chestnut trees of *Neuvecelle*, and the pear tree of *Miroir*.

To those who love the poetry of ruins and the historic recel, I recommend an excursion to the castle of Ripaille, or to the dismantled fort of the Allinges, which has given hospitality to St. Francis of Sales, the apostle of Chablais.

In fine, amateurs of mountain excursions will find here ample satisfaction to their tastes. They can make the ascent of the lofty Memise, or the teeth of Oche, stone giants, from the summits of which we discover Mount

Blanc, Mount Rosa, and the lakes of the Canton of Bern, without speaking of the Lake of Leman that we view in its whole extent.

Let us add, to be complete, that M. Chéronnet, the proprietor of Amphion, purposes to give the bathers the surprise of several balls or soirées. These fêtes by the gaiety and distraction which they procure cannot but happily second the medical treatment.

The bathing season opens on the 15th of May, and closes with the month of October.

In the preceding years the bathers of Amphion were obliged to go to Evian to consult the physicians of that place. M. Chéronnet, in order to avoid useless changes of place, often inconvenient for his numerous visitors, has secured the aid of a physician, Dr. Alrig, who will be entrusted with the Medical charge of the establishment. The patients thus finding themselves the objects of a constant surveillance, can accomplish their cure on the spot, and in the best conditions of security and comfort. In order that the patients may be able to take their baths at the most convenient hour, the proprietor of the establishment has just added six bath rooms to those which already exist. In short, he is going to proceed, under the direction of Dr. Alrig, to the installation of a hydro-therapeutic hall, which will contain all the necessary arrangements, and baths of every description of running water, and at a low temperature. With such complete arrangements it will be easy to us to suit the most varied hydro-therapeutic indications, and there is no doubt but that the addition of this powerful therapeutic agent to the thermal treatment can produce, in prudent and experienced hands, favourable and lasting results.

Amphion has a chalybeate spring of ancient celebrity, and three alkaline springs, which in mineralisation and therapeutic effects are nothing behind the neighbouring ones of Evian. These springs all flow in the park at some yards' distance from each other.

Who does not already see that the union in the same place of mineral waters different in their composition and therapeutic effects will cause most varied curative application? This association of two waters supplying one another's deficiencies makes Amphion an exceptional thermal station, a station which, favoured besides by its wonderful topographic situation, and its admirable ensemble of hygienic conditions, is destined to rival in a few years more celebrated thermal establishments.

The chalybeate waters of Amphion have been known since time immemorial. They were formerly frequented by the Counts of Savoy, the Kings of Sardinia, and a crowd of noblemen. They have also given rise to a great number of notices and publications, which vaunt its beneficent waters. First analysed by Tingry, the celebrated chemist of Geneva, who consecrated their memory, they have been analysed a second time by the Academy of Medicine of Paris, which by the organ of M. Gaultier of Clanbry, has given them a very favourable report. We give below the third analysis, which was made in 1862 by the Assay Office of the School of Mines at Paris.

Analysis of One Litre.

Free carbonic acid and bi-carbonates ...	0.105
Carbonic acid of the carbonates ...	0.118
Silica	0.021
Oxide of iron. Alumina	Traces.
Lime	0.102
Magnesia	Traces.
Potash	Traces.
Soda	0.008
Sulphuric acid	Traces.
Hydrochloric acid	Traces.
Total	0.354

Analysis of the supply proceeding from the chalybeate spring of Amphion, giving 150 litres of water a minute,

at a constant temperature of 8° C. 100 parts were experimented upon.

Carbonic acid	5.18
Sulphuric acid	1.93
Phosphoric acid	5.65
Silica	17.62
Oxide of iron. alumina	} 41.35
Oxide of manganese	
Water and organic matter	12.07
Hygrometric water	7.3
Arsenic, about	0.02
	<hr/>
	9.93

This water is perfectly limpid, which is due to the excess of carbonic acid, which holds in a perfect state of solution its mineral elements, especially its iron salts. It was taken at its point of emergence, and under the best conditions. Its rate of delivery is 105 litres per minute. Its temperature is constantly and in every season 8° C. It has a styptic and "atramentaire" flavour, slightly masked, however, by a slight sulphurous taste due to its passage through the turfy soil. It disengages in its exit from the spring numerous bubbles of carbonic acid, which has caused it to be compared to the spring of Géronstère at Spa; slightly gaseous like that we only feel its intoxicating affect when it is drunk to excess. It spreads like the spring of Géronstère a slight sulphurous odour, and contains almost as large a dose of iron.

Amphion possesses three alkaline springs, but as they all three contain the same mineral elements, it will be only a question of that of which the supply is the most considerable, and which has hitherto been solely employed. This spring was discovered in 1861 by M. Chéronnet on the side of the hill which overlooks the establishment. It has been taken under the best conditions. Just underneath the point where it was discovered, a subterranean, stone, vaulted reservoir has been constructed, able to contain about 15,000 litres of water; from thence the spring has been conducted by a large lead pipe in the park of the establishment, and by the of the chalybeate spring.

It furnishes twelve litres per minute in winter and eight in summer. It is without flavour and any special taste, fresh, clear, and very agreeable to drink. The temperature is from 12° to 13° C. It ought then to be classed with the waters of Evian, amongst the *fresh alkaline waters*.

An analysis of this spring was made in 1862 by the Assay Office of the School of Mines. The result is given below. *One litre* was analysed. We have grouped in the same table the two principal springs of Evian, the Cachat spring, and Bonnevie spring. Our readers can thus convince themselves at a glance that the three springs have as almost identical medical composition.

SPRINGS.

SUBSTANCES IN THE WATERS	SPRINGS.		
	Amphion.	Evian-Bonnevie.	Evian-Cachat.
Free carbonic acid and bi-carbonates	.132	.097	.061
Carbonic acid of the carbonates	.145	.000	.000
Bi-carbonate of lime	.167	.221	.194
" magnesia	.006	.015	.013
" soda	.017	.020	.020
" potash	Traces	.007	.006
Phosphate of soda	.000	.001	.001
Silica	.007	.000	.000
Oxide of iron. Alumina	Traces	"	"
Sulphuric acid	"	"	"
Hydrochloric acid	"	"	"
Totals	.474	.361	.295

From this table the reader will be easily convinced that in the alkaline water of Amphion the total of the mineral principles is higher than the totals of the springs of Evian, in the proportion of 47 to 36 and 29. The dif-

ference in favour of Amphion is due to the fact that it contains a larger quantity of free carbonic acid or of the carbonates. It is then more gaseous, which is a guarantee of its unalterability in the longest journey.

Decisively, these three springs having the same temperature, the same physical characteristics being found in the same situation, and traversing the same geological beds, ought, logically, to have the same therapeutic effects. The experience of the last years fully confirms this theory. A large number of bathers, sometimes at Evian and sometimes at Amphion, have proved that they felt the same effects. We will cite Dr. Blache, Vice-President of the Academy of Medicine, whose high scientific authority will not be questioned. This eminent practitioner has used the alkaline water of Amphion for drinking and for bathing, and after a month's stay, has gone away full of enthusiasm for the water, and delighted with the relief it had given to his sufferings.

Trousseau says alkalies are as necessary to the accomplishment of certain functions as oxygen to respiration.

1. When introduced into the stomach they have the property of neutralising the free or superabundant acids that organ holds. They have besides, according to the experiments of M. Claude Bernard, the property of exciting the secretion of the gastric juice. According to M. Petrequin, of Lyons, the portion of these salts which is decomposed in the stomach unites with the lactic acid to form the alkaline lactates which assist in bringing the materials of nutrition into the chyle and into the lymph.

2. A portion of these alkalies is absorbed and passes into the blood, of which it augments the alkalinity, which permits the sugar and starch matters introduced by alimentation to unite with the oxygen, and by their combustion to augment respiration and calorification.

3. They render the blood more fluid, which gives it the power of penetrating better into the interstices of our tissues, and of accelerating and regulating the circulation in the capillaries, by penetrating into their most minute ramifications. This blood becomes at the same time more viscous, and thus becomes more fit to direct the phenomena of endosmose and exosmose, and to effect the different compositions and decompositions which constitute organic life.

4. According to these ideas it is easy to divine in what manner they act on the secretions.

Taken into the liver by the absorbents, they liquify the elements of the bile, and hinder them from collecting to form calculi. This bile becomes more alkaline, emulsifies and saponifies the fatty matters, which by this fact will sustain a more perfect combustion, and so become a new source of heat. By penetrating to the kidneys they neutralise the acidity of the urine, and are not long in rendering it alkaline. By accelerating the urinary secretion they disembarass the kidneys of the sand or gravel which they can contain. Besides, the urine becomes alkaline neutralises the uric acid in excess proceeding from the incomplete oxygenation of the nitrogenous products in the organism. In fine they re-establish or augment the functions of the skin suppressed or altered by a languishing capillary circulation, the perspiration normally acid becomes alkaline, once more bringing about the impregnation of the entire economy by these agents. These different properties, therefore, make the alkaline waters *liquifying* and *melting* agents, excitors of nutrition, respiration, calorification, and the biliary secretions cutaneous and urinary.

ADDRESS IN MIDWIFERY (a).

By EVORY KENNEDY, M.D.,

Late Master of the Dublin Lying-in Hospital; President of the Section.

(Continued from page 121.)

CASE VIII. The Whole Circle of the Os Uteri thrown off in Labour.—A patient, in her third labour, which was

(a) Delivered at Birmingham, August, 1872.

somewhat violent, had slight hæmorrhage. The head was well engaged in the pelvis, and some fleshy mass was found to protrude from the vulva. The pains increasing, a complete circular ring, about three-eighths of an inch thick by an inch in breadth, escaped, which, on examination, proved to be the detached os uteri in its entirety. The labour proceeded rapidly. There was very little hæmorrhage; and the patient made a favourable recovery, the lochial discharge continuing longer and being more offensive than usual. Of the after-history of this case, and whether she bore more children, I am ignorant.

CASE IX. Procidencia of Gravid Uterus in the Sixth Month of Pregnancy reduced successfully: Living Child six Weeks after Reduction.—M. B. was admitted into hospital April 4th, 1838, with the extraordinary displacement of the gravid uterus exhibited in this drawing. She considered herself just entering on the sixth month of pregnancy, and had suffered for some time from bearing down and pelvic distress. The tumour, now perceptible, had protruded suddenly beyond the parts the day before admission. It appeared larger than a pint mug, polished, dry, and red, with the os uteri enlarged, but not patulous; rather puckered, as you perceive; plugged with yellow mucus, and with several ulcers, as if the effect of abrasion, on the most pendulous part surrounding the os. The ulcers were touched with solid nitrate of silver. The patient was placed on her back with the pelvis elevated by pillows. The protrusion was smeared well with hog's lard; and then the protruding tumour was gently but steadily embraced with both my hands, and pressed with the points of the fingers all round at its connexion with the pelvis, whilst it was at the same moment gently forced up with the palms of my hands formed into a cup-shape. This pressure was continued steadily for some minutes in the direction of the outlet of the pelvis, upwards and backwards, and, as it yielded, directly upwards, when I had the gratification of finding it glide safely upwards into the replaced vagina; by following it still up with the fingers, it was pushed high in the pelvis. A full opiate was now administered. An assistant was placed to watch, with the hand on the perinæum; and the patient fell into a profound sleep, and awoke, after some hours, free from inconvenience. She was retained for some time perfectly quiet, with the hips slightly elevated, and went home well. At the expiration of six weeks, she was delivered of a healthy living child, which appeared of about seven and a half months' development, and it survived.

CASE X. Acephalous Fœtus; totally brainless; acutely sensitive.—A female child, otherwise fully formed and developed, was born acephalous—in fact, totally devoid of brain. It survived its birth one hour and a half, breathing and crying loudly; the expirations were rather convulsive in their character. Its voice was very strong. It was acutely sensitive to impressions made on the surface of the body, and moved its limbs. We could not satisfy ourselves whether it heard or saw. It cried so much on inserting food in its mouth, that it was impossible to ascertain whether it could perform the act of deglutition. In other cases of acephalous fœtuses, we usually found a rudimentary portion of the middle lobe of the brain; and they rarely survived beyond a few gasps, if so much. The malformation is occasionally combined with spina bifida and contortions of the limbs; but some, like this child, are fully developed—indeed, the shoulders were so much so, as to create a difficulty in their extraction. The *post-mortem* examination, in which I was assisted by the late Dr. Todd of King's College, presented no feature worth recording, beyond what I have mentioned.

CASE XI. Spina Bifida.—In June, 1872, I was consulted about a child four months old, reasonably well developed, healthy, and with every prospect of continued vitality and health, save the existence of a head somewhat large, but with tardy development of the parietal and frontal bones, leaving the large fontanelle unossified, congenital dislocation of the ankles forwards, and a spina bifida of the

lumbar vertebrae. This measured two inches in diameter, with a projecting polished membranous covering, enclosing an elastic fluctuating sac. In fact, there was a total absence of the integumentary, ligamentous, and bony covering of the spinal cord, the thickened dura mater supplying their place. I exhibit a model of this case. The child, a girl, shows quite as much evidence of mind and powers of observation as four months' children generally do. My directions hitherto have been to take every precaution to prevent the injury or rupture of the cyst. A chambered shield of gutta percha, lined with padded silk, is being adapted to prevent the possibility of accidental injury; and I have it in contemplation to try a plastic operation when the age, promise of enduring life, and condition of the child justify it. It would be extremely gratifying to me to have the suggestions of my *confrères* with reference to the future dealing with this remarkable case; more especially of those who have met with similar cases in their practice. How long have they been known to survive, and how they were treated?

CASE XIII. Vesico-vaginal Fistula cured by twisted Suture.—On August 12th, 1837, H. Byrne, æt. 25, was sent from the country suffering from vesico-vaginal fistula. The opening was longitudinal, about five lines long, with considerable loss of substance. It was about three inches from the urethral orifice. The bowels were well freed. She was placed on the abdomen on the edge of a table, with a bolster interposed. My four curved beak-tractors were introduced, and, her limbs being held fast by assistants, I pared the edges of the fistula with a scalpel, cutting on an ebony spatula; and, having introduced three short needles into the wounded edges, drew them together with a twisted suture. A perforated shot was now squeezed on the end of each needle, an elastic catheter introduced into the bladder, and the patient was placed lying on her abdomen, on bolsters stitched together longitudinally. She was retained in this position, and closely watched day and night, by a relay of nurses, who never left her. The urine flowed freely from the urethra into a bladder attached to the catheter. Her bowels were washed out by lavement. Not a drop of urine escaped from the vagina. The sutures were cut out on the fifth day, and the needles removed, when the union was complete. She left the hospital in a fortnight perfectly well. I had the advantage of the assistance of my late colleague, the distinguished surgeon Mr. Abraham Collis, in this case; and I cannot easily forget the gratification he evinced when he made a final examination of the bladder before the patient left the hospital, nor the significant manner in which he answered my inquiry whether he could find any hole. "No, doctor; I can't find a hole, unless I make one;" and added, with a peculiarly expressive shrug of his shoulders, with which those who knew him were familiar, "I am sure you don't wish me to do that."

CASE XIV. Vesico-vaginal Fistula treated by Cautey. Honor Lattan was admitted in May, 1836, with a vesico-vaginal fistula an inch and a half from the meatus, transversely oval, with the edges thinned off, and large enough to admit the point of the little finger. She suffered from constant escape of urine ever since her first of two labours in the country, which lasted for seventy-two hours. The vulva was excoriated, red, tumid, and tender, with gritty deposit. Lead-poultices and the use of the catheter were had recourse to for some days; and then she was placed on the abdomen on the table, the tractors were introduced, and the button actual cautey applied to the stricture surrounding the aperture. After this, she was slung from the bedposts in a sheet, lying upon the abdomen, with the catheter introduced. This operation was repeated at intervals, at first of five days, and subsequently at intervals of eight or ten days; and she left on the 26th of July, able to retain her urine for two hours, and only disturbed twice at night. The edges were again touched on the 11th of August; and, on the 30th, she described herself as free from inconvenience, retaining her urine regularly for three hours through the day, and being even

able to go on often without relieving the bladder more than three times in the day and twice at night. The spot remaining ununited was reduced to a small pin-hole, such as you see represented in this drawing of Bridget Byrne, a case somewhat similarly treated, and with similar results.

CASE XV. Vesico-vaginal Fistula treated by Cautey and Pessary.—Mary Cathcart (November, 1837) suffered from a slough of the vesico-vaginal septum in her first labour in the country. The fistula was small, circular, about two inches and a half from the meatus, and rather to the right side. This was considerably diminished by one application of the actual cautey a month after her third delivery; but, as this was followed by peritonitis, it was determined not to repeat any operation. A cast model of the vagina, made of dentist's wax, was taken. This was done by introducing the soft wax, with a tape for extraction imbedded in its centre, through a speculum partially introduced. A caoutchouc mould was made from this, which fitted the vagina accurately, and was worn constantly as a pessary. The result of this simple contrivance, to use the words of my then clinical clerk, copied from this report, was, that "she experienced much comfort, being enabled by its use to retain her urine to a convenient length of time, and evacuate the contents of the bladder at pleasure, without withdrawing the instrument." I should, however, mention that I have since several times repeated this plan, using the cautey in preference to the ligature, or where this was objected to; and it has generally enabled the patient to retain her urine for some time. It has, however, not always been attended with the same amount of success. In fact, it is more adapted to very small fistulous apertures, or to those that have been reduced by the use of the cautey.

CASE XVI. Total Occlusion of Vagina: Operation: Animation suspended for upwards of twenty-two Minutes by Chloroform.—Some years ago, Dr. Ringland and I were called upon to operate in a case of a lady with total occlusion of the vagina. The examination could only be made through the rectum. The anterior and posterior walls of the vagina were united almost throughout their whole length. There was a sense of fluctuation perceptible on pressing the finger high up into the bowel. A tumid fulness was perceptible over the pubes, to about the extent of a six months' pregnancy. The bladder and rectum were emptied; and the patient was placed on her back, on a high couch, with the limbs flexed and held by assistants, as in lithotomy. The patient was with some little difficulty brought under the influence of chloroform. I had commenced the operation, when she struggled so that I was obliged to desist, and assist in bringing her completely under its influence, before again commencing. A catheter was introduced into the bladder, and the dissection was proceeded with, cutting and separating the adherent tissues with the blade and handle of the scalpel alternately; now introducing the finger into the rectum, and again feeling through the anterior wall for the catheter, to avoid approaching too closely to either cavity—a scarcely appreciable divergence in either direction being fraught with misery to our patient for life. From the difficulties and risk attending the operation, it was necessarily a tedious one; "rapidity" in such an operation being a convertible term for "destruction." At length, after cutting for three inches upwards, and dissecting a new vaginal canal by dividing throughout this extent a layer of condensed structure not more than the sixth of an inch in thickness, we had the gratification of coming to a small pouch at the upper part of the vagina, which communicated with the distended uterus, and from which poured a quantity of grumous retained menstrual fluid. Having thoroughly enlarged the opening at the upper part, so as to correspond with the dimensions of the canal throughout, I got up from the operation to receive a shock such as I never experienced before or since. Our attention was called by the chloroformist to our patient, who lay with her head over the edge of the table, her jaw fallen, and to all appearance dead. There was no respiration; no pulse at the wrist;

no action of the heart. I took out my watch, in order to take care that attempts to restore animation should be continued for a sufficient time before desisting, but without a hope that they could be attended with success. Experience in resuscitation of infants had led me to expect little from forcible inflation of the lungs by inserting a tube into the trachea, but much from a continuous and persistent imitation of the act of respiration by regular pressure on the elastic ribs of the subject—producing, as nearly as possible, the systole and diastole of the lungs and chest-frame, as observed in nature. Without a moment's delay, I sprang upon the high table, so as to command the prostrate woman; and, kneeling across her, placed a spread hand over the lower ribs, and kept up an artificial respiratory action in the lungs of about twenty pressures in a minute. In the meantime, all the available means of resuscitation were most assiduously carried out by my friend Dr. Ringland and his assistants. Friction and sinapisms were applied to the arms, legs, and surface. As speedily as buckets of warm water could be procured, her hands, feet, and limbs were immersed in it. These efforts were persisted in, whilst minute after minute was anxiously counted, with not the slightest evidence of restored vitality. At length, our souls absolutely sickened with disappointment, and, I may add, all hope having fled, we were, at the expiration of twenty-two minutes, repaid for our exertions by a convulsive gasp. Nearly a minute took place before a second occurred. Then they recurred at half-minute intervals; and eventually the natural breathing became established, and the artificial respiration was desisted from. Sickness now set in. She was unable to assist in the involuntary efforts to discharge the stomach. The food blocked up the œsophagus and posterior fauces; but, by drawing the head and neck over the edge of the table, and giving her the advantage of gravity whilst the finger was passed into the œsophagus, the obstructing food and mucus were removed, and respiration was established. A second collapse ensued after a few minutes, consequent on the evacuation of the uterus; but after this she recovered without a check. A curious circumstance, in a psychological point of view, should not be omitted. When she recovered her sensibility and powers of perception and speech, within a few minutes after respiration was re-established, looking steadfastly at one of the physicians present, she asked slowly and with some effort, "Is that Jesus Christ?" Where was her soul during that period of suspended animation? It might be surmised that this case would shake one's confidence in chloroform. With me, it had an entirely contrary effect, as it proved the power—perhaps I should say the capability—of restoring vitality suspended by its use under circumstances apparently hopeless.

CASE XVII. Fall from Window in the Seventh Month of Gestation.—In January, 1834, I was called to see a woman in Beresford Street, who had fallen from a window three storeys high, whilst stretching clothes on a rope line made fast to a projecting pole. She not only fell about thirty feet, but, her hip striking a small wooden baluster that protected the area, the baluster gave way, and she was precipitated about seven feet lower into the area. This woman was in the seventh month of pregnancy. I found her still suffering from the shock, with a small quick pulse, very anxious countenance, the surface and extremities cold; but, with the exception of a contusion on the hip and some slight abrasions on her hands, she had received no apparent injury. As she was in very poor circumstances, I had her carefully carried into one of the surgical wards of the Richmond Hospital. A full anodyne was administered, and she awoke, after some hours' sleep, without any injury or ailment save the contusion and abrasions referred to. After resting in hospital for a few days, she left quite well. In the course of a fortnight, she made a voyage from Dublin to Liverpool, and suffered from sea-sickness. She returned and was admitted into the Dublin Lying-in Hospital. At the end of her ninth month, she had an easy labour of a living child, and recovered without a

check. Sir Astley Cooper might well say, in reference to the patient who died from diffuse inflammation following the scratch of a pin, and the recovery after perforation of the thorax with a gig-shaft, "Gentlemen, you will thus perceive there are some cases that you cannot cure, whilst there are others that you cannot kill."

CASE XVIII. Nursing Twelve Months after Delivery of a Dead Child.—Mary Kenny, æt. 22, had had a still-born child nine months after marriage, computed to have been a month dead. She secreted milk freely, and continued to have milk in her breasts for a month after delivery. At the expiration of a year, she took a relative's child to dry nurse. She had the child to sleep with her, and applied it to her breasts in the night. On the following morning, she noticed her chemise stained with milk that had escaped from the nipples. She continued nursing this child regularly for seven months. The child was satisfied, and thrived remarkably well. Her catamenia, which had continued regularly from the time of her confinement, ceased, and did not return whilst she nursed. The child died of dentition when seven months old; and two years afterwards, when this case was noted, a milky fluid could be drawn from the breasts.

BRITISH MEDICAL ASSOCIATION.

ADDRESS IN MEDICINE.

By SAMUEL WILKS, M.D., F.R.C.P., F.R.S.,

Physician and Lecturer on Medicine at Guy's Hospital, Examiner in Medicine at the Royal College of Surgeons, &c.

(Concluded.)

I CANNOT leave the subject of treatment without adverting to a method of practice which, I believe, is far from uncommon, and which some delude themselves is philosophic. We are called to a patient, and we feel extreme doubt as to the best plan of action; two opposite methods of treatment pass through our minds; the case may be one of pneumonia, and we are considering, on the one hand, the value of depletory measures, and, on the other, of stimulating; we halt between two opinions, and silently saying *in medio tutissimus ibis*, adopt a compromise. Now, if being in doubt, we did nothing, there would be reason in the plan; but to propose to oneself two methods and split the difference, is to adopt a treatment which I take to be most unscientific.

A very natural result of the instinctive feeling which all persons have to gain relief for their individual troubles without giving a thought to the deeper question of the cause of them, is seen in their endeavours to compel Medical men to give their undivided attention to particular parts of the body: I cannot say particular complaints, for of these the public knows nothing; but to particular organs and symptoms. They thus insist on one Medical man devoting his powers to the heart, another to the kidney, another to paralysis; and, if he do not choose to obey their behest, the public, if they seek advice from him, are pleased to ticket him with the name of kidney or liver doctor, according to the organ they believe to be at fault. Is the public right in its demand, and the Profession in submitting to it? If what I have already said be true, there can only be one answer. If the greater insight into the mechanism of man and the morbid changes to which his body is liable obliges us to take an increasingly comprehensive view of disease and its treatment, the idea of chopping up the body into separate parts must be strongly deprecated. Who would be most likely to possess the more correct view of the nature of cancer—he who saw it in some of its external forms only in a cancer hospital, or he who in a general hospital would meet with it in all parts of the body, and had an opportunity of comparing it with other morbid growths? It may be asked: Has not scientific advance encouraged specialism? I should say decidedly not. If history showed me that the more comprehensive method was adopted in ignorant times, and that a higher civilisation had brought with it the division of the art into sections, I would submit to the fallacy

of my argument; but my reading of history proves the contrary. The votive offerings in our British Museum are monuments to the special cures practised by the Greek Medical men; and in Egypt, we are told by Herodotus, every place was full of physicians, there being some doctors for the eyes, others for the teeth, some for the head, and others for the belly. If we read what was taking place in our own country a hundred years ago, we shall find this so-called division of labour carried to a much greater extent than now. Thus Goldsmith writes: "In other countries the physician pretends to cure diseases in the lump. The same doctor who combats the gout in the toe, shall pretend to prescribe for a pain in the head; and he who at one time cures a consumption, shall at another give drugs for a dropsy. How absurd and ridiculous! This is being a mere Jack of all trades. Is the animal machine less complicated than a brass-pin? Not less than ten different hands are required to make a brass-pin! and shall the body be set right by one single operator? The English are sensible of this force of reasoning; they have one doctor for the eyes, another for the toes; they have their sciatic doctors and inoculating doctors; they have one doctor who is modestly content with securing them from bug-bites, and five hundred who prescribe for the bite of mad dogs." Other contemporary writing will show that there was good reason for drawing this picture; and, if it in any way approaches the truth, it is evident that the fondness for specialities has been waning, and a larger view of the practice of medicine, founded on a more scientific basis, is taking its place. With the progress in our science and art, this meddling with particular organs and symptoms has decreased; and this is what might have been expected, if the method were shown to be due to a lesser knowledge than exists at the present day. The division of our art into specialities, according to the manner of the Egyptians, is antiquated and unphilosophic. If so, the public suffer from their exactions. If they oblige a man to devote all his time to the skin, they reap the reward when they find a necrosed bone cannot be cured by arsenic. If they compel a man to give all his time to gout, they should not quarrel with him if he cannot reduce a dislocated thumb by potash water; or if they oblige a third to do nothing but look down their throats, it is their own fault when they discover that their best days are passed for taking good advice for their phthisis. I would not say for a moment that a physician or surgeon should not devote more attention to one subject than another. In fact, whether he choose it or not, his own turn of mind will incline him to do so; and, if this be the case, his advice will naturally be sought in the department in which he has most studied; but, having a knowledge of the whole range of disease, he is not likely to be misled or foolish enough to treat one symptom without considering its bearing upon others. The evil of so doing is less likely to occur now than formerly; for an ophthalmic surgeon may divine that blindness can arise from causes remote from the eye; and the obstetric physician knows that, with a highly nervous or hypochondriacal woman, his whole thoughts need not be given to the uterus; and thus, at the present time, every author of note detaches hysteria from any necessary disturbance of the womb. Should, however, an exclusive attention be given to this organ, absolute harm to the patient may result; and one feels often sorry to witness many cases of morbid irritability of body perpetuated by it. One of the few specialities where a long and extended experience enables the professor to gain a larger knowledge than the mass of Medical men can possess, is mental disease; but this is one of the few least patronised by the public. At least, from my own observation it has seemed that, when a man's mind is going wrong, the last person whose aid he seeks is the "mad-doctor." The division into medicine and surgery, even, has its evils; and thus I am convinced that the best advisers for the people at large are the general practitioners.

Not only does the Profession suffer in its true scientific dignity by its being divided—not only do those who seek advice often meet with disaster; but the poorer portions of the community suffer from the diversion of benevolence into wrong channels. It is a standing disgrace to England, and especially to London, that so little is contributed towards the maintenance of general hospitals. If we except those which are largely endowed, there is not one of the other great hospitals which has not often overrun its funds, or is forced to close some of its wards from sheer poverty. The public would not subscribe their guineas for so mean an object as the cure of an inflammation of the lungs, an erysipelas, or a broken leg, but choose rather to give their hundreds and thousands to maintain some special institution which was pleasing to their fancy.

Sentiment often entirely rules; and thus the abject poor, with their vulgar wants, are neglected; whilst any amount of money can be raised to expend on a beautiful house and grounds for the cure of hopeless jabbering idiots. I might also allude to the evil of drawing away cases from the hospitals where pupils resort for instruction, although it is therein, and from the physicians and surgeons attached thereto, and who rarely practise specialities, that they gain a knowledge of those very subjects which are supposed to be known only to the few. In whatever way, therefore, the subject is handled, the evils of the so-called division of labour are evident. There can be only one thing said on the other side; that it gives those engaged in the practice of one department greater facility in manipulation and the use of remedies. It may be true, if your watch be out of order, that the boy who can make a pin would be better able to set it right than the watch-maker if a pin only were required; but I think, for all this, the boy's advice would not in the first instance be sought.

In what, then, does our science consist? According to my idea, we study the peculiar tendencies and disposition of the human frame. We see in it the proneness to various changes and degenerations. We see acute rapid affections running their course in a few days, whose origin is legion. We see the body attacked by causes altogether from without. In all these cases, we stand by and watch. We have found various substances in Nature, the most valuable having their histories lost in tradition, which are useful in arresting morbid processes, or in assisting in the completion of necessary changes. Such medicines when given as experience dictates, have saved the lives of numbers. This must be positively spoken of digitalis, opium, iodide of potassium, and some other remedies. I say we are still watching, for we do not yet know the value of symptoms; and, until we do, we have no right to interfere. Our sole duty is to act empirically. Nothing can be said against any system under which the greatest number have recovered. Suppose a number of hungry people crying for bread, and blessing their benefactor who continually supplied their wants; he would gain more credit than the man with a large political creed who devised a political scheme to prevent starvation; but undeservedly so, for the latter would be the truer philanthropist. So it is with the art of medicine. Apollo was the God of Medicine; and why? Because, says Bacon, "the variable composition of man's body hath made it a body easy to distemper, and therefore the poets did well to conjoin music and medicine in Apollo; because the office of medicine is but to tune this curious harp of man's body and to reduce it to harmony." It will be remembered that both the Society of Apothecaries and the College of Surgeons have chosen for their mottos adjacent lines from Ovid's *Daphne*, in which Apollo says, "Opiferque per orbem dicor," and "Quæ prorsum omnibus artes." I think a text for another theme might be got out of the intermediate line,

"*Hei mehi! quod nullis amor est medicabilis herbis.*"

which might imply that affections having a moral cause must be treated by moral means. Hysteria, for example, is too often perpetuated by the too officious interference of the Medical man. Moral means often avail when all the herbs have proved futile. *Daphne* was right in running away from Apollo when he said he was a doctor.

Special Report

ON

DISEASES OF THE THROAT.

Edited for the "MEDICAL PRESS AND CIRCULAR."

By PROSSER JAMES, M.D., M.R.C.P.,

Physician to the Hospital for Diseases of the Throat and to the North London Consumption Hospital; Lecturer on *Materia Medica* and Therapeutics at the London Hospital.

IV.—LARYNGOSCOPY.—(Continued.)

Difficulties and Obstacles. Movement of Mirror. Retching. Arching or Thickness of the Tongue. Enlarged Tonsils. Irritability of the Fauces and means of relieving this Condition. The Epiglottis—its Form and Position, &c.

EXPERIENCED laryngoscopists will often place the

mirror in the fauces so accurately as to obtain instantaneous views of the vocal cords in a number of cases successively. But even those in constant practice do not always thus easily succeed, though the movements they make after the mirror touches the uvula may be so slight and so rapid as to be almost unnoticed. On the other hand the beginner cannot expect to become an expert in his first lesson, and he will acquire the necessary tact more easily by deliberate movements than by any attempt at rapidity. If the image of the vocal cords does not appear at once, the position of the mirror must be altered to a slight extent. A common mistake is to move it too much, a very slight movement deflecting the rays of light to a considerable distance. This fact may be illustrated by the following engraving—

FIG. 16.

in which *m* represents the position of the mirror, and *g* that of the glottis. A ray of light from the observer's eye falling upon the mirror *m*, is reflected to the glottis *g*, of which an image appears at *m*. A very slight inclination of the mirror may throw the light along either of the dotted lines, in which case the image of *g* will be replaced by another, *a* or *e*, as the case may be.

The most likely movement to be required is a slight elevation of the hand. If too near the centre and in the way of the light the hand must at the same moment pass nearer to the corner of the mouth. This movement is seldom required with my rectangular-handled mirrors, hence they are often found easier to use by learners. Whatever movement be necessary should be made deliberately and continuously, not in jerks. It can then be arrested the moment the laryngeal image is brought into view. There can be no objection to resting one or two fingers on the patient's cheek in order to steady the hand; but with practice many will find this unnecessary.

The mirror should not be kept too long at a time in the patient's mouth, nor should it be moved about too much. Retching is not so likely to be produced by two or three separate introductions. In fact, timid patients gain confidence as they find the mirror can be introduced without inconveniencing them.

This retching—the dread of patients who have never been examined by the laryngoscope, and the bugbear of those who are learning to use the instrument—is most likely to be excited by touching the tongue with the

mirror. Bearing this in mind, the error will mostly be easily avoided. Another reason for care in this respect, is that the mirror becomes covered with secretion, and its reflecting power thereby diminished or even destroyed. On the other hand, while avoiding the tongue by carrying the mirror high enough, we should not let it actually touch the palate. It is, in fact, to be carried between the tongue and roof of the mouth, touching nothing until it comes in contact with the uvula. I have known beginners derive some assistance by letting the stem slide along the upper front teeth, and in a difficult case this may be done, but practice soon makes this unnecessary.

Occasionally the uvula is itself found in contact with the tongue. In this case, the patient is to be requested to take a deep breath, or to say "a" (or emit any other vowel sound), as during these acts the uvula is raised, and so the mirror more easily placed.

The same plan should be adopted when the tongue involuntarily arches itself so much as to almost fill the mouth, and also in cases in which the root of the tongue seems preternaturally thick.

In the majority of cases the arching of the tongue is due to apprehension on the part of the patient, or inability to control its movements. Sir Thomas Watson (*a*) recommends in such cases, that the patient should practise before a looking-glass. It is easy thus to acquire the art of keeping the tongue in such a position as to admit of the introduction of the laryngoscope in the simplest manner, as already shown in Fig. 10.

But such complete command is unnecessary, and to acquire it occupies time. The best way is to tell the patient to put out his tongue, and to hold the protruded organ between the thumb and forefinger of the left hand covered with a napkin. This plan practised with the utmost gentleness very seldom fails.

The patient should also be told to breathe through the mouth, and not through the nose.

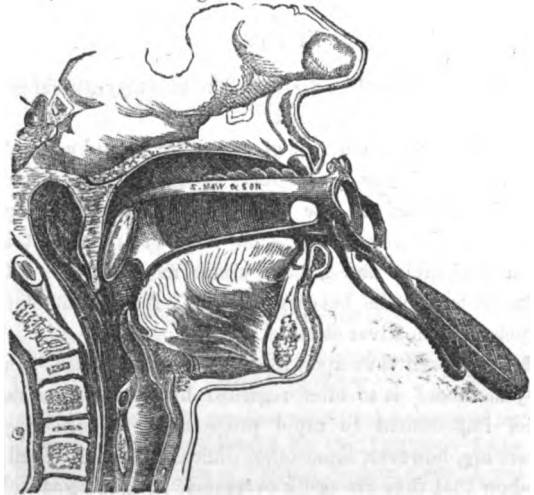

FIG. 17.

A very nervous patient may be advantageously set to

(*a*) "The Laryngoscope." Two Lectures at the Royal College of Physicians by George Johnson, M.D. London. 1864.

hold the tongue himself. This diverts his attention, and should local treatment become necessary, the physician will want both his hands free.

In exceptional cases, especially in those in which the root of the tongue is unusually thick, it has been proposed to hold it by a variety of instruments. Of these, Labordette's *speculum laryngien*, has perhaps been most used, but like many similar contrivances, has not met with general favour. It is somewhat complicated, necessitates a degree of force not so completely perceptible to the physician as it should be, and is not unlikely itself to excite vomiting or some other inconvenience.

If any instrument be used to control the tongue it cannot be too simple. It is this quality that constitutes the value of my tongue depressor, which is so easily managed that with little practice it becomes, so to say, a mere addition of the physician's fingers. But even this is more useful for rhinoscopy than for laryngoscopy. Its use is illustrated in Fig. 18, which differs in several

FIG. 18.

other respects from Fig. 10 (a). The two may, therefore, be advantageously compared.

Instead of an instrument of any kind the physician's forefinger can be used, and some operators have almost entirely discarded the use of tongue depressors. It appears to me, however, that some kind of instrument is often preferable and its use seems more delicate. If "fingers were made before forks" we have not therefore dispensed with silver at table.

I have dwelt thus upon the tongue, because that "unruly member" is so often regarded by beginners as the chief impediment to rapid progress in laryngoscopy. There are, however, some other difficulties which, if only to show that they are easily overcome, it may be as well to mention here.

One of these is enlarged tonsils. A moderate degree

of hypertrophy is the chief cause for the use of oval mirrors, but sometimes these organs are so much enlarged as to give rise to considerable difficulty. They are then manifestly in a condition to require treatment, which should not be delayed, unless some contra-indication exist.

Great irritability of the fauces occasionally proves an obstacle to overcome which, requires tact on the part of the physician, and confidence on that of the patient. Many cases yield to the simple plan of sucking ice for a few minutes before the introduction of the mirror. Where time is not of importance the patient may educate himself before a looking-glass, and gradually accustom the throat to the contact of instruments. Some have recommended painting the fauces with various local astringents, or saturating the sponge probang with them, and applying it from time to time. A better method of employing these remedies is by means of the atomiser. In fact a patient educating himself will find an astringent gargle, or the atomiser of great service.

A whiff of chloroform or ether has been proposed, but is not to be justified unless in urgent cases.

The internal use of the bromides has also been recommended. There is no doubt that anaesthesia of the fauces, more or less complete, may be produced by these drugs in large doses, but they must be pushed to the point of saturating the system in order to attain the end, and few would think it right to subject a patient to bromism for this purpose. The use of small doses is as futile as the employment of gargles containing a little bromide, on which some have depended. An alum gargle would be far more effectual.

An irritable condition of the fauces is common in some stages of congestion and inflammation. The local remedies for these diseases are then the best applications. In laryngeal phthisis there is often great irritability, and this is mostly relieved by inhalations of atomised sprays, or by such soothing vapours as may otherwise be indicated.

Tact and gentleness will, in these cases, as well as in physiological irritability, almost always succeed, if the directions as to respiration, vocalisation, and other points be carefully followed.

STUDENTS' COLUMN.

SYNOPTICAL REVIEW OF THE OFFICIAL PREPARATIONS OF THE BRITISH PHARMACOPŒIA.

BY W. HANDSEL GRIFFITHS, PH.D., L.R.C.P.,
L.R.C.S. Edin.,

'Assistant-Librarian Royal College of Surgeons in Ireland.

OLEA (OILS) (a).

These are distilled or expressed; they are enumerated in the following table:—

(a) These will be more fully discussed when considering the *Materia Medica* of the Pharmacopœia.

CLASS I.—DISTILLED OILS.

- (a). From the fresh flowering herb.
Oleum Menthæ Piperitæ.
 " Menthæ Viridis.
 " Ruta.
- (b). From the fresh tops.
Oleum Sabinæ.
- (c). From the leaves.
Oleum Cajuputi.
- (d). From the bark.
Oleum Cinnamomi.
- (e). From the oleo-resin.
Oleum Copaibæ.
 " Terebinthinæ.
- (f). From the flower.
Oleum Anthemidis.
 " Caryophylli (bud).
 " Lavandulæ.
 " Rosmarini (flowering tops).
- (g). From the fruit.
Oleum Anethi,
 " Anisi.
 " Carui.
 " Coriandri.
 " Cubebæ.
 " Juniperi.
 " Pimentæ.
- (h). From the seed-kernel.
Oleum Myristicæ.
- i). Distilled with water from the seed after expression of the fixed oil.
Oleum Sinapis.

CLASS II.—EXPRESSED OILS.

- (a). From the fresh peel.
Oleum Limonis.
- This oil is sometimes distilled.
- (b). From the fruit.
Oleum Olivæ.
 - (c). From the seeds.
Oleum Amygdalæ.
 " Crotonis.
 " Lini.
 " Myristicæ Expressum.
 " Ricini.
 " Theobromæ.

Heat is employed in the expression of *Oleum Theobromæ* and *Oleum Myristicæ Expressum*.

Oleum Morrhuæ is extracted from the fresh liver of *Gadus Morrhuæ* by a heat not exceeding 180°.

The following are the preparations into the composition of which the oils enter:—

Oleum Amygdalæ ni. Unguentum Cetacei, Unguentum Hydrargyri Oxidi Rubri, Unguentum Plumbi Subacetatis Compositum, Unguentum Simplex.

Oleum Anisi ni. Essentia Anisi, Tinctura Camphoræ Composita, Tinctura Opii Ammoniata.

Oleum Anthemidis ni. Extractum Anthemidis.

Oleum Cajuputi ni. Linimentum Crotonis, and Spiritus Cajuputi.

Oleum Carui ni. Confectio Scammonii, and Pilula Aloes Barbadosis.

Oleum Caryophylli ni. Confectio Scammonii, Pilula Colocyntidis Composita, and Pilula Colocyntidis et Hyoscyami.

Oleum Coriandri ni. Syrupus Sennæ.

Oleum Crotonis ni. Linimentum Crotonis.

Oleum Juniperi ni. Spiritus Juniperi.

Oleum Lavandulæ ni. Linimentum camphoræ Compositum, Spiritus Lavandulæ, and Tinctura Lavandulæ Composita.

Oleum Limonis ni. Linimentum Potassii Iodide cum Sæpone, and Spiritus Ammoniæ Aromaticus.

Oleum Menthæ Piperitæ ni. Aqua Menthæ Piperitæ, Essentia Menthæ Piperitæ, Pilula Rhei Compositus and Spiritus Menthæ Piperitæ.

Oleum Menthæ Viridis ni. Aqua Menthæ Viridis.

Oleum Myristicæ ni. Pilula Aloes Socotrinæ, Spiritus Ammoniæ Aromaticus, and Spiritus Myristicæ.

Oleum Myristicæ Expressum ni. Emplastrum Calefaciens, and Emplastrum Picis.

Oleum Olivæ ni. Charta Epispastica, Cataplasma, Lini Emplastrum Ammoniaci cum Hydrargyro, Emplastrum Cevati Saponis, Emplastrum Hydrargyri, Emplastrum Picis, Emplastrum Plumbi, Enema Magnesiæ Sulphatis, Linimentum Ammoniæ, Linimentum Calcis, Linimentum Camphoræ, Unguentum Cantharidis, Unguentum Hydrargyri Compositum, Unguentum Hydrargyri Nitratis, and Unguentum Veratriæ.

Oleum Ricini ni. Collodium Flexile, Linimentum Sinapis Compositum, and Pilula Hydrargyri Sub-chloride Composita.

Oleum Rosmarini ni. Linimentum Saponis, Spiritus Rosmarini, and Tinctura Lavandulæ Composita.

Oleum Sinapis ni. Linimentum Sinapis Compositum.

Oleum Terebinthinæ ni. Confectio Enema, Linimentum, and Unguentum Terebinthinæ, and Linimentum Terebinthinæ Aceticum.

Oleum Theobromæ ni. all the suppositories.

REGISTERED FOR TRANSMISSION ABROAD.

THE MEDICAL PRESS AND CIRCULAR

is published simultaneously in London, Dublin, and Edinburgh, every Wednesday morning. Price 6d. Post free, 5½d.

POST FREE TO ANNUAL SUBSCRIBERS £1 2 6

" IF PAID IN ADVANCE 1 0 0

*. Post-office Orders and Cheques to be drawn in favour of—
 A. A. TINDALL, 20, King William Street, Strand, London, W.C.
 A. H. JACOB, Molesworth Hall, Molesworth Street, Dublin.
 MACLACHLAN and STEWART, South Bridge, Edinburgh.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIÈRE, Publishers to the Académie de Médecine, Paris—post free in advance, £1 6s. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLMER and ROGERS; Baltimore, by Messrs. KELLY and PIET; Philadelphia, by Messrs. LIPPINCOTT and Co., and Dr. BUTLER, post free in advance, £1 6s., about six and a-half dollars; or direct from the Offices in this country for the same amount, by the new Post-office Order system.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 11, 1872.

LEVELLING UP THE LANDMARKS OF THE PROFESSION.

OUR readers will recollect that in the course of last year a Medical Act was passed by the Canadian Legislature under the provisions of which a Medical Council was constructed on a similar basis to that which has proved so delightfully effective in the "old country." The passing of this Act gave rise to bloody affray between the homeopaths and eclectics and the legitimate members of the Pro-

fession, which resulted in the admission into the new Medical Council of certain persons professing these forms of quackery.

This Council met for the first time last month, and was composed of seventeen physicians and surgeons, four homœopaths, and five eclectic. In the course of debate one of the members said that as the eclectic had nothing distinctive in their body they ought to fuse with the general Profession, and in this way a suggested diminution in the number of Council members would take place.

Dr. Muir, one of the eclectic representatives, said that the extinction of that body was inevitable, as the facilities afforded students in Canada for preparing for the allopathic examination were more favourable than for eclectic. Another member expressed himself as pleased with the turn things had taken, *as it would henceforth allow allopaths and eclectic to meet in consultation.*

The Council diverted itself by a debate with reference to a breach of etiquette on the part of Dr. Carson, one of its members, which elicited considerable discussion of a personal character. The substance of the charge was, that Dr. Carson is engaged in the manufacture and sale of patent medicines. One of these nostrums, the *female regulator*, was singled out for attack. Dr. Carson tried in various ways to wriggle out of the position, but enough was elicited to show that he was connected with this disreputable business, and a resolution was moved, to strike his name from all committees of the Council.

Dr. Lawrence was of opinion that the Council was only half doing its duty in removing his name from all committees. He deemed it monstrous that they should have one amongst them guilty of such acts. Dr. Edwards looked upon Carson's advertisement as sheer quackery. He thought it time for the Council to put its foot down in the matter. McGill College, Montreal, had threatened to cancel the diploma of a man who had put forth such medicines. Dr. Carson was severely censured by many other members of the Council, including members of his own body. The motion was carried by a majority of 14 to 6, and recorded in the minutes of the Council.

The perusal of the record of these proceedings is eminently calculated to mitigate the disgust and anger which the Profession in our own country almost universally entertain. After all, our own Medical Council is nothing worse than useless, expensive, voluble, and obstructive. We have not yet, thank Heaven! reached the climax when matters Medical are legislated by avowed quacks, and when a representative lawgiver is openly convicted of trading in the most abominable quack nostrums. Perhaps after all Medical reformers who agitate for the deposition of King Log may not have a sufficient fear of King Stork before their eyes.

A MUDDY BUSINESS.

In the article headed Chloralum in our last number, we quoted from the *Pharmaceutical Journal* a paragraph suggesting criticism of the Board of Trade in connection with disinfectants, which ended somewhat as follows:— "We want to know if the new thing [chloralum] is a true thing, and most naturally appeal to the Medical adviser of the Board, if such officer exist." This very proper appeal will, we trust, be responded to by the officer or officers in question; for they owe it to themselves and the Profession to which they belong, to exone-

rate themselves from the charge of having advised the remarkable course of action which has been pursued in this matter. The gentlemen who have acted since the year 1867, as the Medical advisers of the Board of Trade, are, we have been informed, Mr. Harry Leach, Senior Medical Officer, Dreadnought Seamen's Hospital, and Dr. W. Dickson, Medical Inspector of Her Majesty's Customs. We heartily join our pharmaceutical *confrère* in demanding of them an explanation of the circumstances which led to the insertion of chloralum in the merchant shipping medicine scale, and consequently its obligatory shipment on board all cargo vessels, and use for sanitary purposes, when there was hardly anything beyond the assertions of its manufacturers to show it to be a disinfectant in any other sense than that wherein common salt is one. We take this opportunity also to request the favour from Messrs. Leach and Dickson, of a few words of explanation touching the retention on the medicine scale of Carbolic Acid, after the Ship-owners' Association had so clearly proved it to be totally unsuited for ships' use, being a product which many ship-owners even refused to take on board their vessels on freight, on account of the injury caused to cargo by its offensive exhalations; and finally we should like to see answered by them or others the following simple questions:—

At whose expense is the "Ship Captains' Medical Guide" printed?

To whom belongs the copyright?

By whose authority have the words "all rights reserved" been printed on the title page?

Into whose pocket go the monies that are paid for the advertisements which appear in the Guide!

THE REMUNERATION OF MEDICAL MEN IN SCOTLAND.

RECENTLY there appeared in the columns of a contemporary a very able and exhaustive letter, by Dr. Black, of Glasgow, on "Special Hospital Abuse" in that city. Dr. Black, who is a true Medical reformer, did not deary that grievance too strongly, and we trust his suggestions will not be thrown away. It is not our intention to supplement or to controvert his remarks, but rather to bring under the notice of the Profession another social grievance still more disastrous to our status and interests. We refer to the degrading practice of undervaluing our services.

Although long ago we directed the attention of the Profession to this subject, but little appreciable good has resulted, and in one district—which we have made the subject of our investigations—the sixpenny charge is as rampant as ever, for the abuses complained of (like certain diseases) are, for the most part, endemic to particular districts of Scotland.

The one to which we particularly refer is situated in Ayrshire. Thank Heaven! we cannot be accused of writing through jealous or splenetic motives, our lines having fallen in more pleasant places, where the community properly appreciate the status and remuneration of Medical men.

Can city practitioners fail to be astonished if the following be the *bona fide* scale of fees adopted by a surgeon of thirty years' experience? Midwifery, from 2s. 6s. 1s.; advice, 6d.; consultations, 1s.; other charges *proportionately* moderate.

We have never seen the above printed (how could a printer's bill be paid under the circumstances?), but we have again and again known it practised. Fortunately for the honour of the district, the sixpenny circle is a limited one; and there are those who prefer a limited practice to popularity of such a questionable kind.

How, we ask, can the young practitioner, with his exalted notions of professional dignity, compete with such a class? He must inevitably be dragged into the quagmire of poverty with his sixpenny neighbour, though (through refusing the sixpence) he arrives at that undesirable haven by a more honourable road than his senior brother. If this foul social blot reflected only on the wilful suicide, we should say nothing (we might even slightly chuckle at his self-imposed penury); but unfortunately the disease is, in its effects, contagious, and every member of the Profession is neglecting his duty by refusing to declaim against it. Could city practitioners be persuaded that a radius of practice of from fifteen to twenty miles, necessitating daily and nightly work, does not afford a remuneration that will justify taxation? In other words, it is less than £100 per annum! No wonder the "externe" is shabby, the "buggy" unseemly, and that the horse, from an indisputable family likeness, may safely claim kindred with Don Quixote's Rozinante. How could it be otherwise?

We have again and again called attention to abuses of this kind in other localities, and have more than once specified those who are thus dragging down their professional brethren into the quagmire of poverty. We have made inquiries before referring particularly to Scotland, and on this occasion we touch the subject as cautiously as we do reluctantly. We are, however, by no means disposed to let it rest here, and are quite open to further information on the subject. At the same time with our invariable practice of fair play we are willing to receive any defence or apology that may be offered by those concerned. Will any one defend the sixpenny charge? We trow not. Will one who values his services at that price find time to apologise for it? Our columns are fairly open. His time cannot be so very valuable. Has he the moral courage to affix his name to a letter in our columns?

Notes on Current Topics.

Spread of Cholera.

In his address on "Public Medicine," the Rev. Samuel Houghton, M.D., D.C.L., F.R.S., maintained that cholera was usually imported into Ireland from England. He said:—

"In 1866, it was proved, beyond the possibility of doubt, that the cholera was imported into Ireland; and we could trace the cases through the parts of Dublin, Belfast, Drogheda, Wexborough; and we could lay our hands on cases, and say that these came through the canals and other ways from Sheffield, Liverpool, or Bristol. Our isolated position gives us peculiar advantages for the study of epidemics, and for the determining whether they are, or are not, the result of contagion. With regard to small-pox, there is less difference of opinion than with regard to other diseases; but no one has undertaken the study of the subjects connected with epidemics who has not become, like myself, an ardent contagionist. One of the

advantages of our isolated condition is, that we in Dublin can make Liverpool our Medical barometer. We know when there is an epidemic at Liverpool that we shall have it as well. In all cases of an epidemic which affects Dublin and Liverpool, Liverpool has it first. I went to Liverpool when the cholera of 1866 was raging, and made the most minute inquiries; and Dr. Trench, with the greatest kindness and courtesy, placed his tables and all other information in his possession at my disposal. By the means of these tables and the information which Dr. Trench gave me, I was enabled to mark out the course the disease would take in Dublin, and this before it came to the city. In the mortality of Liverpool, a curve of a remarkable mathematical shape appeared; and, by enlarging the curve, I could predict, in a general way, what would be the mortality of the disease which was coming to Dublin. And this prediction was verified in a remarkable degree; for, afterwards, we found that the total mortality in Dublin was what we said it would be after looking at the mortality in Liverpool, and we were enabled to say when it was at its maximum. So you see that Dublin is as well off, or as badly off, just as you like, as Liverpool in regard to hygienic conditions; and neither town is what it should be in regard to sanitary regulations—in fact, they are upon a par. Now, when I come to small-pox, we have another element to deal with, which we have not in other epidemics; for in this disease we have a means of protection in vaccination, and we can see how well or how ill a town has been protected by the vaccination laws being carried out. We see the small-pox sweeping its way over this island, and its greater or less virulence is a test of our diligence, or of the diligence of those who have gone before us, in protecting the population against this terrible scourge."

Vaccination or Death.

THE vaccino-phobiacs would do well to ponder the lesson read by Dr. Houghton at Birmingham, and which supports by facts and figures the conclusions long accepted by the Medical world and the immense majority of the educated public. He said:—

"When I come to England, I am astonished to find intelligent persons in numbers, who, for some reason, come forward publicly to oppose the process of vaccination. Some of these people express a strong doubt—an honest doubt—whether the mortality from small-pox is really as fearful as the doctors say. To get a proper basis of calculations as to the mortality from small-pox among unvaccinated persons, we must go back to the records of past generations in this and other countries; and we find this astonishing result, that from 60 to 70 in every 100 persons attacked by small-pox must die, if not vaccinated. Some people have the idea that this is a bugaboo of the doctors, and that they need not necessarily die if not vaccinated. Of course it is impossible now to get the experience of an immense number of persons who have not been vaccinated, to give them the small-pox, and see how many would die. This experiment could not be easily carried out. Therefore I adopted another method. I took it for granted that the writers and records of the close of the last century were correct. The average which they gave was that 66 per cent. of every class—men, women, and children—must die if they had got the small-pox and were not vaccinated; whereas, of those who were attacked after being well vaccinated, the number of deaths was only 6·6 per cent. This reduction of the mortality from 66 to between 6 and 7 per cent. represents what vaccination has done. The value of vaccination is, therefore, established beyond the possibility of a doubt, and I think that this is a subject on which the Medical Profession should speak out. Should not Birmingham, with her literary men and newspapers, lead the public on this great question? I wrote to my friend Dr. Hayden, of the Mater Misericordiæ Hospital in Dublin, to send me

the total number of small-pox cases treated there, and of the deaths; and I undertook, from these figures, to calculate the number of those who were vaccinated, and those who were not. This forms a very simple problem in mathematics, of which I will not trouble you with more than the results attained. From the figures sent me, I calculated, though I had never seen a patient, that 120 of the cases treated at the Hospital had not been vaccinated. I wrote to tell Dr. Hayden this; and he wrote back to say that the number recorded as known to be unvaccinated was 119. Since I have come to Birmingham, Mr. Woolley has kindly placed at my disposal all the information he possessed, and I hereby beg to tender him my warmest thanks for his courtesy. Although Birmingham has suffered what I cannot but regard as a most contemptible epidemic, the facts are strikingly illustrative of what, to my mind, is the truth of the principle which I am placing before you. Since the 18th November, 1871, there have been 1,911 cases of small-pox, of which 262 have died. I leave out the cases remaining under treatment. I calculated from those figures that 230 persons in Birmingham who had been attacked with the disease had never been vaccinated. I found in Mr. Woolley's returns that the certainly non-vaccinated were 209, while doubtful cases numbered 44. Well, it was fair in such a case to split the difference and call it 22, and, as that suited my theory very well, I adopted it; and when I added them to the 209 it made 231, which was only one above my calculation. It is like the trick of a conjurer, walking into the town, asking the number of small-pox cases and deaths, never having seen the patients, and yet telling the people of the town how many were vaccinated and how many were not. Dr. Trench tells me that 1,616 cases were treated in the Liverpool hospitals; the deaths were 375; from that I calculated that the non-vaccinated cases numbered 451. The number actually recorded as non-vaccinated was 432, being 19 less; but I am perfectly certain that to those should be added several of those properly set down in the reports as doubtful. This opens up a problem highly interesting to the Profession of medicine. As the mathematician in his closet can direct the astronomer in what part of the heavens and when to look for certain planets, so the progress of science and medicine can tell with certainty when and where certain districts will be attacked with epidemics. The records of the fearful epidemics and the plagues of the Middle Ages have perished; the poor have perished with no man to regard them. Even the writings of Defoe may be searched in vain for any statistics of the Great Plague which would satisfy the demands of modern Medical science. But, by examining into the records of our own times, we shall be able to read back the history of the epidemics of the past, the number and percentages of the mortality of those who suffered, who lie forgotten in their graves, and whose history no one has recorded."

Insanity or Kleptomania.

A DISTURBER of the order and completeness of the study-tables of Medical men in London has, for a long time, been wanted by the police. We are informed that for some weeks past, an individual of respectable exterior has been in the habit of calling at the houses of consultants. Should he find them within, he would give some trivial excuse to the servant and go as quickly as he came. On the other hand, should Dr. So-and-so be absent, which was most probable during certain hours, he would ask permission to write a note, and while the servant was absent for a moment to fetch him an envelope or other necessary, quietly possess himself of anything within reach, and be as mute as a mouse when the servant returned. Nothing seems to have been too big for his capacious pockets, nor too small for his notice, but barometers, cases of surgical instruments, postage stamps, and loose

cash received more immediate attention. On Friday last he was politely shown the inside of a prison, to await his trial at the Central Criminal Court. At his primary examination before the magistrate, he pleaded temporary insanity, but Mr. Knox *actually* refused to entertain this plea, with such an army of pawnbrokers before him. Having regard for our own libraries, we hope Her Majesty's Government may be induced to take care of this poor fellow for many years to come.

Incapacity for Military Service.

WE inserted a week or two ago a letter of inquiry as to short sight incapacitating from military service. Several correspondents are desirous of ascertaining how far various diseases interfere with the prospect of military employment in various countries. We now, therefore, print the following list of those diseases which absolutely incapacitate from service in most armies, in the hope that it will be an ample reply to all inquiries:—

1. Albinism.
2. Mental disorders—imbecility, idiotism.
3. Alopecia (extensive and permanent).
4. Anasarca, or œdema owing to organic causes.
5. Anemia, chloro-anemia.
6. Strictures of urethra (considerable).
7. Aphonia—dyspnœa—dumbness—stammering (permanent).
8. Ascites.
9. Asthma.
10. Cachectic scurvy, scrofulus, paludial.
11. Calculi in any organ with functional disturbance.
12. Cancer, its different species, and other degenerations.
13. Caries or extensive necrosis.
14. Caries or necrosis of all the teeth.
15. Caries, or a bad state of a large number of teeth with softening or ulceration (chronic) of gums.
16. Old catarrhes of slight consistency, or adherent with loss of substance, muscular or bony, chiefly in the lower extremities.
17. Permanent contraction of the flexor or extensor muscles, or their constant relaxation, preventing free muscular exercise.
18. Cophosis or permanent deafness of one or both ears.
19. Dysecea or considerable weakness of hearing.
20. Bucal dysodia, or constant foul breath.
21. Cutaneous dysodia, or habitual fœtid perspiration.
22. Epilepsy, fits epileptiform or apoplectiform catalepsy, ecstasy, chorea, and other nervous and convulsive diseases, habitual or periodical.
23. Epispadias, hypospadias and pleurospadias situated in the space comprehended between the middle of the penis to its root.
24. Scurvy well characterised.
25. Scrofulous tumours, voluminous, ulcerated, or in great numbers.
26. Fistulæ, communicating with bony cavities, serous cavities, or articulations; with the substance of spongy bones, or with important organs, with notable functional lesions.
27. Habitual hæmorrhage or periodical (hæmoptysis, hæmatemesis, hæmaturia, &c.)
28. Voluminous hæmorrhoids, ulcerated, constant hæmorrhoidal flux.
29. Hernia of abdominal viscera, in whatever degree.
30. Vaginal hydrocele, or of the spermatic chord impeding walking.
31. Incontinence of urine.
32. Incontinence of fœcal evacuations.
33. Lesions or deformities of the organs of sense.
34. do. do. in the head.
35. do. do. do. neck.
36. do. do. do. trunk.

37. Lesions or deformities of the legs and arms.
 38. do. do. do. hands.
 39. do. do. do. feet.

N.B.—When these impede the functions of the economy or manifestly embarrass the use of the uniform, equipments, riding on horseback, and the use of weapons of defence.

40. Eye diseases and their dependencies, impeding vision or rendering it incomplete for military duties, or producing habitual suffering.
 Myopia must be characterised by the impossibility to read at 35 centimetres distance with concave glasses, Nos. 3 to 5, French scale, and to distinguish distant objects with glasses Nos. 6 and 7.
41. Diseases of the auditive duct, with permanent functional lesion.
42. Diseases of the organs of circulation, and their dependencies, with appreciable alterations.
43. Diseases of the organs of respiration, with chronic symptoms.
44. Diseases of the digestive organs, ancient or permanent.
45. Diseases of the genito-urinary organs, serious or chronic.
46. Chronic cutaneous diseases, contagious and of a bad character, or of disgusting appearance.
47. Diseases producing permanent difficulty of mastication, deglutition, speaking, or breathing.
48. Necrosis and neuralgia, habitual with disturbance of important functions.
49. Obesity or general polysarcia—abdominal.
50. Ozæna, or chronic foetid purulent discharge from the nose, nasal fossæ, or from the frontal or maxillary sinuses.
51. General or partial paralysis, with permanent character.
52. Loss of one ear, or both eyes, or of their use.
53. Loss of all the superior or inferior incisor and canine teeth, or of all the molars of one or both maxillaries.
54. Loss of nose.
55. Loss of part or entire ear.
56. Loss of both testicles.
57. Loss of part or the whole of the external genital organs.
58. Loss of one arm, leg, foot, or hand, of the thumb, or of the last phalanx of the same, of the great toe, or of its last phalanx, of two fingers or toes, or their last phalange, or of the movement of either of these.
59. Large polypi.
60. Fall of rectum, or permanent stricture of same.
61. Permanent retention of testicles in abdominal cavity of one or both in the canal, or in the inguinal ring or perineum.
62. Chronic gout and rheumatism.
63. Siatorrhœa, or involuntary and abundant flow of saliva.
64. General syphilis.
65. Phthisis, laryngeal, bronchial, or pulmonary.
66. Tumour of hard and soft parts, impeding functions, or necessary movements for the service.
67. Ulcers, ancient, extensive, atonic, or of bad character.
68. Large or multiple varicose veins in any part impeding movement, particularly of the lower extremities.

Inspectors-General of Hospitals—Indian Leave and Allowances of.

THE following paragraph of a military letter from the Secretary of State for India has been published for general information :—

I have decided that an Inspector-General or a Deputy Inspector-General of Hospitals of the Indian Service, on leave in Europe, who has not completed his tour of service and has vacated his appointment, shall be granted the British pay of his rank after vacating his appointment

and be allowed to count the period of his absence from India, since vacation of appointment, as service for pension, subject always to the rule as to five years' absence from India.

English Hospitals in Paris.

Two hospitals for Englishmen exist in Paris. The first, Galignani's Hospital for the English and Americans, was founded in 1865 by Anthony and William Galignani, who endowed it with a gift of half a million of francs. This hospital is situated in the Boulevard Bonneau, at Neuilly, and contains twenty beds for each sex. Secondly, Sir Richard Wallace has founded an hospital of twenty-four beds near the Porte Maillot. It is nearly always full, the Parisian jockey furnishing a considerable contingent of surgical cases. It is attended by Drs. J. Cormack and Allan Herbert, who, with Sir Richard Wallace and the English Consul, form the committee of the "Hertford British Hospital."

Nomenclature à la Mode.

A WRITER in the *Chicago Medical Journal* thus elucidates the pathology of hysteria :—

"The more common form of hysteria is that in which the erethism of the emotional centres has affected those of ideation—the same sequence of events absorbed in most regularly progressive insanities—and the other symptoms are joined with wrong mental action, distorted conception of things, and the patient comes to have a fixed delusion."

Our "ideation" is not equal to the assimilation of this erudite definition. We decline the task of interpretation, lest our "wrong mental action" might involve us in a "distorted conception of things," and ultimately in "progressive insanities."

Increases of Medical Officers' Salaries.

THE Irish Poor-law Commissioners have sanctioned the resolutions of the committee of the following districts to increase the salaries of the Medical officers:—Dundalk and Barrowstown districts to £140 a year each; Ravensdale and Carlingford districts to £120 a year each, and of the Medical officers of the Louth and Dromiskin dispensary districts to £125 and £75 a year respectively, as proposed by the Board of Guardians.

The Pay of Army Surgeons.

THIS subject is constantly exciting discussion, and is certainly deserving the attention not only of those immediately concerned, but of all good citizens, for the welfare of the State depends so largely on the efficiency of the military forces (and the same observation applies equally to the sister service), and this so much on the Medical Department, that the questions involved ought to receive public attention.

In our recent investigations into the foreign services we have had occasion to contrast our own as compared with those of other countries. The difference of the value of money in this country and on the continent should be kept in mind in all contrasts made.

In Portugal the last revision took place in 1870, when the Medical Department was settled upon the following plan :—

ART. 1.—The Staff of Division and Brigade Surgeons is

fixed on two Division Surgeons and six Brigade Surgeons. They will be distributed as follows:—

	Surgeons.	
	Division.	Brigade.
Ministry of War, Health Department	—	1
1st Military Division at Head Quarters	1	1
2nd " " " "	—	1
3rd " " " "	1	—
4th " " " "	—	1
Permanent Military Hospitals } (Directors)	—	2
Total	2	6

ART. 2.—To the division and brigade surgeons attached to the general head-quarters of the different military divisions on the Continent will belong exclusively the duties which fall to them by the regulations now in force.

§ I. The brigade surgeon attached to the head-quarters of the 1st division, besides the work he has to accomplish in that department, will have to do work in the 5th division, as at Funchal (Madeira), when the Minister of War shall think fit.

ART. 3.—When the division and brigade surgeons have to make inspections out of their district and ordinary residence, they will be allowed an extra sum of 2,000 reis (about nine shillings) a day during the time of inspection, provided that time does not exceed thirty days in each three months.

§ I. This allowance is independent of all other emoluments.

§ II. The same allowance will be made to the Medical man who may have to do the work of sanitary inspector during the absence of any division or brigade surgeon of any military division.

§ III. To the surgeons of division and brigade on duty in the 1st military division, though they may be both employed at the same time in inspecting, they cannot receive more than the expenses incurred corresponding to three months, and this only in cases where there has been a reduction in the staff of inspectors. Exception will be always made in the inspections at the Azores and Madeira, which will be always considered extraordinary.

ART. 4.—The surgeons of different corps who have to inspect recruits out of the locality where they are quartered will receive an indemnity of 1,500 reis, 6s. 8d. per day, inclusive of the days of going and coming. The maximum of this allowance must not exceed four days each time.

Table of allowances, according to Art. 27 of the decree of 6th October, 1851, to personnel of the sanitary company, at the ambulances, hospitals, and to those who have to perform the same duties, according to Art. 32.

Grades.	Pay per diem.
1st Sergeant	Reis 160 = 8d.
2nd Sergeant.....	" 120 = 6d.
Furriel	" 160 = 8d.
Corporal	" 060 = 3d.
Auspecada	" 050 = 2½d.
Soldier	" 040 = 2d.

Surgeon-in-Chief of the Army.

Pay - - -	780,000 Reis.	
Gratification - -	360,000	£ s. d.
Allowance for 1 horse	91,250 = 1,231,250	= 273 10 0.
		Half Pay 144 0 0.

Division Surgeon.

Pay - - -	696,000	
Gratification - -	360,000	£ s. d.
Allowance for 1 horse	91,250 = 1,147,250	= 255 0 0.
		Half Pay 128 0 0.

Brigade Surgeon.

Pay - - -	648,000	£ s. d.
Gratification - -	300,000 = 943,000	= 210 0 0.
		Half Pay 120 0 0.

		<i>Staff Surgeon.</i>	
Pay - - -	360,000	£ s. d.	
Gratification - -	240,000 = 600,000	= 133 0 0.	
			Half Pay 64 0 0

		<i>Assistant Surgeon.</i>	
Pay - - -	336,000	£ s. d.	
Gratification - -	120,000 = 456,000	= 101 10 0.	
			Half Pay 40 0 0.

		<i>Pharmacutists.</i>	
1st Class—Pay - -	360,000	£ s. d.	
Gratification, 120,000 =	480,000	= 106 0 0.	
2nd Class—Pay - -	336,000		
Gratification, 60,000 =	396,000	88 0 0.	

		<i>Veterinary Surgeon.</i>	
1st Class—Pay - -	360,000 = £80	0s. 0d.	
2nd Class—Pay - -	336,000 = £74	10s. 0d.	

1st Sergeant.....	Pay 255	Gratification 160 = 415 = 2s. 0d.
2nd Sergeant ...	" 215	" 120 = 335 = 1s. 5d.
Furriel	" 195	" 160 = 355 = 1s. 6d.
Corporal	" 115	" 60 = 175 0s. 7d.
Soldier	" 85	" 40 = 125 = 0s. 6d.

MR. G. F. RODWELL, natural science master in Marlborough College, has been appointed lecturer on experimental philosophy in Guy's Hospital.

THE ex-Queen of Naples, Maria Sofia, who resides near Munich, has just had a bad fall from her horse, the accident causing a miscarriage of a male child.

LONDON is now extremely healthy; during the week ending Saturday last 2,188 births and 1,236 deaths were registered in London. The births exceeded by six, whilst the deaths were 239 below the average numbers in the corresponding week of the last ten years. There were only eight deaths from small-pox.

LONDON PAUPERISM is also much reduced as compared with the corresponding week of last year, the Local Government Board returns show 7,066 fewer paupers receiving poor relief in the metropolis.

It is stated that the Chair of Materia Medica in Queen's College, Galway, has become vacant by the resignation of Professor McCoy. The professorship is worth between two and three hundred pounds a-year.

THE University of Munich, at its recent 400th anniversary, conferred upon Mr. Simon, the Medical officer to the Privy Council, the honorary diploma of Doctor of Medicine, "propter præclarissima de sanitate publicâ tuenda atque augendâ merita."

Scraps from the Editor's Table.

REVIVAL OF THE ANTIPHLOGISTIC TREATMENT.

A FEW years ago, when the idea of inflammation always took the lead in pathology and therapeutics, the depleting plan of treatment was in general use; and it was pushed to such extremes that a natural reaction was the result. Taking advantage of the revolutionary moment, when the pendulum was about to swing in the opposite direction, a number of sects sprang up in opposition to regular medicine, and courted the multitude by their noisy declamation against old abuses.

Homœopathy, hydropathy, and other vagaries of one idea, contrived to enlist a large army of honest fools, smart knaves, and rickety philosophists, in a crusade against regular medicine, which it best suited their purposes to define as the indiscriminate and excessive use of the lancet, calomel, and tartar emetic. From this harp of three strings the schismatics succeeded in evoking a harmonious strain in opposition to regular medicine, albeit they were in mortal conflict one with another on all distinctive points. The popular mind was easily infected with the prejudice thus inspired, and physicians themselves gradually conformed to it by discarding valuable therapeutic agencies, assigning no better reason for doing so than because they had been abused by their predecessors. The vulgar outcry against bleeding and other instrumentalities of the ancient heroic practice gradually and stealthily modified the views of the Profession and revolutionised the treatment of disease, so far as almost to banish from the armament of the practitioner a number of the most potent agents of the *materia medica*. To such an extent has this irrational proscription been carried, that there are many physicians in full practice and high standing who have never so much as witnessed the process of venesection, who never resort to topical bloodletting, or to lancing the gums in dentition, or to blisters, and who entirely discard the preparations of mercury and antimony. There appears to us no warrant for such arbitrary and unconditional proscription either in medical logic or in the general principles of science. On the contrary, it belongs to the trickery of charlatans, and its logic is that of their advertisements in the newspapers. Between the habitual and empirical use of certain articles, and their indiscriminate prohibition, we can perceive no essential difference. There is neither reason nor science in either extreme.

But the pendulum which, half a century ago, swung from the extreme point of inflammation and depletion, appears to have passed the opposite extreme, and now begins to vibrate in a backward direction. Of late a number of able writers in England and America, as if by concert of action, have revived the claims of the discarded practice. The healing virtues of the lancet and of calomel are again presented in the light of fact and demonstration. The new generation of doctors begin to discover with something of surprise that bloodletting is not always murder, nor mercury of necessity a poison; but that there is a proper place in rational medicine for these and other potent agents, fashion, prejudice and quackery to the contrary notwithstanding. In the future, physicians will have less dread of popular clamour, whether of the vulgar herd, or of more refined people who have learned just enough of medicine to "intoxicate the brain." Without discarding expectation, conservatism and whiskey, they will readmit into their therapeutics bloodletting, mercury and antimony.—*Pacific Medical and Surgical Journal*.

DEATH FROM OVERWORK.

It is not the lazy or rank-blooded man who is so often struck down as the working man, ignorant of ordinary precautions, or the student or excited business man, whose brain is already on fire and whose nervous system is prostrated by overwork. Our ordinary murderous high pressure system shows its nature nowhere as in the recent records of mortality. Directions for care in exposure, dress and diet, are well enough in their place; but why should we invite death at every moment of our adult lives to give him this cold shoulder at the last? The proportion of children among those stricken down by the recent heat was appalling. Yet the heat was not worse than our forefathers bore and lived to tell us of; and it is quite true that the children carried about with them neither exhausting cares in mind nor too hardly worked bodies; but they had nothing to oppose to the fiery

test but the flaccid limbs and rasped nerves bequeathed to them by either liquor-drinking ancestors or those who make the stimulant of energy and overwork take the place of liquor.—*New York Tribune*.

ON COUNTER-IRRITATION.

(Concluded.)

WHEN, however, a large portion of the surface of the body is exposed to an action affecting the area of the capillaries, the entire circulation is changed as the result. This is shown by the following experiment:—

EXPERIMENT IV.—By means of the sphygmograph, a tracing was obtained of the pulse of a young man in full health and under ordinary conditions, the temperature of the air being about 82° Fahr. The pulse was found to be of fair volume. Without disturbing the instrument, the lower half of the body was then immersed in water at 70° Fahr. After the feeling of chilliness had passed off, a second tracing was taken. The pulse was much larger and stronger. Hot water was then added to the bath, until a temperature of 120° Fahr. was obtained. A third tracing then showed the pulse to have less volume than before, and less tension than in the normal state (a).

The effect of the cold bath in this case was to contract the vessels in that portion of the body to which it was applied. The result was, that the blood, meeting with increased resistance in that half of the body, was distributed in greater proportion to the part where the resistance was normal, and hence a larger pulse at the wrist. When the temperature of the bath was raised to 120°, the vessels of the lower half of the body relaxed, and again presented an easy passage for the blood, restoring the equilibrium, and hence the radial pulse became smaller.

But, aside from this direct action in the immediate vicinity of the part irritated, there may be in some cases another action in parts more remote. A reflex impression may affect the vaso-motor nerves in parts having the requisite nervous or "sympathetic" relation to the one irritated, and this transferred action would then be the same in kind as that already described, and a similar change in the circulation would result. Bernard found that applying acetic acid to the tongue produced a very marked change in the circulation of the sublingual glands, the amount of blood coursing through their capillaries being immensely increased, and the blood in the veins of the glands retaining its arterial hue. Numerous other examples might be cited, showing that the circulation in one part may be modified by irritation in another.

There are, then, as Dr. Smith conceives, four conditions in which counter-irritation may act to relieve pain, or abate inflammation:—

1. When there is a direct vascular connection between the irritated surface and the diseased part. In this case, counter-irritation acts by opening a larger passage for the blood through the sound tissue, and thus diverting the circulation in part from that which is diseased.

2. When a large surface is exposed to the irritating agent, in which case the entire circulation of the body, including that of the diseased part, may be modified.

3. When the irritation is transferred to a distance by reflex action, and there simulates the first condition.

4. When pain is the result of a mechanical cause, which cause may be removed by exciting muscular action through the reflex function; as when, in flatulent colic, the muscular coat of the intestines is brought into action by irritation applied to the abdomen, and expulsion of the flatus results. Of course, two or more of these conditions may coexist, and probably in most cases such is actually the fact, and the result is thus rendered more or less complex.

(a) Illustrated by a cut of the tracings.

If the views advanced respecting the effect of counter-irritation upon the circulation be correct, it follows that the aim should be so to manage the irritation as to cause the greatest possible flow of blood through the part. We should, therefore, stop short of inducing inflammation, as this tends rather to impede or arrest the capillary circulation than to promote it. More effect will be produced by irritating a large surface to a moderate degree, than by exciting an intense action within narrow limits. This is illustrated in the advantage which is derived from "flying blisters" in subacute inflammation of the joints or in sciatica. These blisters are applied for a short time only, so as not to produce complete vesication, and are repeated at short intervals. They are found to be much more efficacious than when the full action of a blister is produced.

It is not intended by this suggestion to ignore the effect which may result from the evacuation of serum by means of vesicants, or of the drain which may be established by maintaining suppuration from a blistered surface. This comes under the head of depletion rather than of counter-irritation, the latter being merely incidental to the former.

In examining the capillary system, we shall find that the skin on the one hand, and the mucous membranes and the solid internal organs on the other, are very richly supplied with these vessels, while the muscular and cellular tissues have much fewer in proportion. Excluding the latter, we may, for the sake of convenience, speak of the cutaneous system and the visceral system of capillaries. These two systems, comprising so great a proportion of all the capillaries in the body, stand in a certain antagonism to each other. The health of the body requires that neither of these should receive for any considerable time an undue proportion of blood. Such a condition involves a double departure from the normal state, as the excess in one system necessitates a corresponding deficiency in the other. Let us suppose, then, that the cutaneous capillaries are by any means increased in diameter to a considerable degree, as they may be, for instance, by the hot bath; we shall find as a result that, the resistance to the flow of the blood through them being diminished, a much larger proportion will seek that channel to reach the venous system than will pass through the capillaries in other portions of the body. As a consequence, the remainder of the body will be left with an insufficient supply. We may sometimes observe the results of this in phenomena appreciable to the individual. Thus, the lassitude felt after the warm bath may be attributed to imperfect nutrition of the muscles from the insufficient supply of blood to them resulting from this action. The tendency to syncope produced by the protracted use of the warm bath is probably owing to the diminished supply of blood to the brain, caused by the increased facility for its passage through the capillaries of the skin. On the same principle, the wakefulness of insanity may sometimes be overcome by hot applications to the chest and abdomen.

The converse of this is observed in the vigour which results from the use of the cold bath, or from exposure to a cold and bracing atmosphere. Here we have the vessels of the skin reduced in calibre, and as a consequence a greater proportion of the blood sent out by each contraction of the heart is compelled to find its way to the veins through the capillaries of the muscular and nervous systems.

But, under certain conditions not well understood, an impression of cold upon the surface leads to such a diminution in the cutaneous circulation, and consequently to such a distention of the visceral capillaries, as to induce a lesion of some one or more of the viscera. The pneumonia, bronchitis, nephritis, or diarrhoea, as the case may be, is then said to be the result of "taking cold." If in the very earliest stage the warm bath or some internal sudorific be resorted to, and a free channel thus opened in the skin for the passage of blood, the internal organ may be relieved, and the threatened disease averted.

But an impression of cold upon the surface may, under some circumstances, prove salutary. Thus, in syncope, we dash cold water into the face and upon the chest, in order,

as we say, to rouse the system by the sudden shock. The shock may perhaps have something to do with the result, but we do not find other means of rousing the nervous system to be equally efficacious. Shaking, flagellation, &c., so useful in opium-poisoning, do not approve themselves to us in this case. But cold water, combining with the shock a sudden contraction of the cutaneous vessels, and thus forcing more blood into the internal organs, including the nerve-centres, is an agent which has been used from time immemorial with success.

Medicines which are supposed to have a certain degree of control over the diameter of the capillaries are described in works on materia medica, and not unfrequently prescribed in cases in which the design is to affect the circulation in some diseased locality through the general action of the drug. The reasoning is as follows:—"This medicine acts upon the capillaries—the capillaries in the diseased organ require such action—ergo, the medicine is indicated." Now, if the diseased part is supposed to be acted upon only as a portion of the general organism, and not from any special relation to the medicine, the employment of the latter must result in disappointment, for the simple reason that, if all the capillaries of the body are acted upon alike, no change in the distribution of the blood will ensue. The most that can happen is, that the labour of the heart will be increased or diminished. The same result would be attained by employing a cardiac sedative or a cardiac stimulant.

These remarks will apply to the use of opium and of ergot as antiphlogistics. Dr. S. does not intend to raise a question as to their efficacy for this purpose, but merely to attack the theory of their supposed mode of action, which he believes to be untenable; unless, indeed, it can be shown that the capillaries of inflamed parts are peculiarly sensitive to their influence.

THERAPEUTICS :

An Address delivered at the Annual Meeting of the Norfolk (Massachusetts) District Medical Society, May 8, 1872

By B. E. COTTING, M.D. HARV.

(From the *Boston Medical and Surgical Journal*, July 4.)

MY FIRST QUESTION

As a Medical Student,—

ITS SOLUTION A SURE BASIS FOR RATIONAL THERAPEUTICS.

(Continued from page 184.)

A GREAT change has indeed been effected, and a great advance has been made, yet these "prejudices" occasionally crop out in the journals we have quoted, and are now and then to be seen lingering in the addresses annually given to students by eminent teachers. One of these, last autumn, declared that he held "the doctrine [of leaving cases to Nature] to be as dangerous as the more ancient doctrine which allowed men to undertake cures in rashness and ignorance"—as though any scientific observations undertaken in the cause of truth, and in the interests of humanity, could be as dangerous as the rude experiments of "rashness and ignorance." The lecturer's lament, sorrowful as it seems to be, that there is a "school" in England inclined to such observations and entertaining the doctrine he inveighs against, is truly encouraging, and marks a great progress in breaking down conventionalisms and "prejudices." The doctrine is quite familiar in this vicinity; has ceased to shock our immediate neighbours; and has begun to be received by some at a distance. For an example of this among many, in an annual address given last year in an adjoining State, it is said "if a case is doubtful it is wiser and safer to let Nature manage it alone;" and, in regard to giving too much medicine or giving too little, "the latter is the

safer of the two." In this there is no leaning to "rashness and ignorance."

It was the fashion within the memory of living men to call the spasmodic and tumultuous essays of "rashness and ignorance" by the popular phrase "heroic treatment"—but that day is past. He who withholds the *anceps remedium* is no longer to be called a sceptic or a timid old woman. "Do not let me hear that called heroic treatment," said Dr. Wilks in a lecture at Guy's Hospital, 1866, "where much and powerful medicine is given." Such treatment is more often dictated by ignorance and cowardice. . . . I call that young man a hero, and his was heroic treatment to insist on a man lying in bed, eating nothing, and taking no medicine. But even this latter heroism, as a distinction through the doctrine involved in it, is also fast passing away. Physicians who a dozen years ago would have shrunk from admitting the doctrine, now, consciously or unconsciously, advocate it, as though it never had been called in question; and the lamentations of opponents plaintively attest its spread throughout the Profession, here and elsewhere. For a little while longer only, will it be thought necessary to becloud its trial by a specious appellation, as that of the "nutritive plan," or the "mint-water treatment;" as though nutrition must not always be an essential in any treatment, or mint-water could be considered an agent of power even by the most credulous.

The solution of my first question does not require an abandonment of any other line of inquiry, or method of investigation into the nature of disease, or the best mode of its management. On the contrary, every suggestion, from whatever source, promising improvement in the knowledge and treatment of disease is to be most heartily welcomed; only its real value to the sick man must ultimately be tested by reference to this solution. Let every conceivable effort be zealously made to ascertain all the characteristics and medical properties of all known or discoverable substances, and to catalogue them in Dispensatories; let chemistry torture out their elements, and authoritatively designate the changes undergone in the system when they are taken into it; let physiology indicate, if it can, the exact tissue, or element, a given drug will ultimately find its way to and act upon, be it a nerve of the heart or blood corpuscle; let the action upon animals be sought out with diligence; furthermore, let the several effects of all proposed substances be carefully observed upon the human economy in health; and then, after that, in what Waring, one of the latest authorities, calls "the only sure way of ascertaining the true properties," in disease also; remembering, according to another high authority, "that whenever we give a man a dose of medicine we really perform an experiment," so little is as yet known of its real action—let all these several methods be followed out to the utmost in a truly scientific spirit, omitting none of the "refinements" of the day—and let no one of us underrate for a moment the brilliant results already derived from such sources—still *the one thing* will be lacking, if the natural history of the course and events of undisturbed disease is not sufficiently known to be taken for a standard and a test.

The effect of a medicine on the system is one thing; the benefit to be derived from it, if any, may be another and quite a different thing. Sleep, for instance, is the frequent termination of a recoverable case of delirium tremens, and, as such, anxiously watched for by sympathising attendants; but the sleep procured by opium, as used in that disease not many years ago, seldom ended the complaint, but sometimes apparently the sufferer. Delirium and wakefulness are often distressing accompaniments of typhoid fever, but the quiet and sleep produced by a hypnotic may prove more dangerous than the evils it is intended to remove. Perspiration is often considered a good sign in the course of a disease, but is it in reality more beneficial than the fever-paroxysm that preceded it? Philosophically speaking, are the last events of a disease any more curative than the earlier ones—each in its own order passing its allotted stages? Why need we so constantly act upon the supposition that disease, whatever our theory of its causation, is necessarily something added to, or else something taken from the system, seeing that such a supposition is gratuitous, that disease may be only (as Sir William Gull says) "a life-process of a perverted kind," and that we as yet know so little of the actual significance of external manifestations.

"The Art of Medicine," says the Father of Medicine, "would not have been invented at first, nor would it have been the subject of investigation (for there would have been no need of it), if, when men are indisposed, the same food and

other articles of regimen which they eat and drink when in good health were proper for them, and if no others were preferable to these. But now necessity made medicine to be sought out and discovered by men, since the same things when administered to the sick, which agreed with them in good health, neither did nor do agree with them." Such was the origin of the Art of Medicine; its crowning glory will be an exact knowledge of the best management of the sick man, what food for his nourishment,—what measures for his comfort and safety,—for the sick man is the disease, according to the last and highest dictum of the eminent attendants on the Prince of Wales; and the science of the sick man includes as an essential the answer still sought for to my first question.

This question of mine, thus asked in the verriancy of youth, has been ever recurring through a somewhat extended and satisfactorily successful term of professional service. Some of the attempts at its solution have, from time to time, been laid before this Society. That there is a lurking hope that they have had some beneficial influence on the manner of viewing disease, and its treatment, here and elsewhere, I shall not be so disingenuous as to deny. To have pulled at the oar in the right direction is of some satisfaction, though the bark might have reached its destination, and gained the prize, without such assistance. This question, asked of myself, before prescribing, at the bedside of each patient in succession, has saved many a one from much of the perturbation inculcated in the books of past generations, and taught too inconsiderately even now, at home and abroad, in the schools. That it has saved from disaster and death it may be presumptuous to assert; but it can be declared with confidence that it has never endangered a single life, nor added to the sufferings of a single individual. If students were generally to begin professional life in this way, their faith in real remedies would increase as they proceeded; and not, as in too many instances, end in complete distrust at last, after a "career made up of a series of failures and successes" in which they seemed to be only insignificant participants.

Moreover, the desired solution, if it could be satisfactorily obtained, would for ever silence the plausible argument of adventurers and impostors, who, no matter how preposterous or nugatory their treatment may be, claim that because recoveries may have followed their treatment, they themselves and their methods are worthy of confidence—for it would then appear, even to the common understanding, that such a supposition is untenable; but in the words of the "solid and accurate" Oesterlen, "so long as physicians appeal to nothing more certain in their practice . . . they must be content to let every one else, even charlatans, appeal to their experience; and . . . the sick will necessarily place the same confidence in, and award the same thanks to them, as to the most able physician."

As we have in part endeavoured to show, a very great advance has been made within the last quarter of a century in the study of the natural history of diseases; and the scepticism in regard to perturbative treatment has already borne most promising fruit. Still the coming student will find the work only partially begun, with abundant necessity remaining for earnest observation and candid investigation. Happily, however, though but begun, progress is less difficult now than the way is opened and the direction pointed out. Incentives also are not wanting. "It is," says the *British Medical Journal*, editorial, Jan. 13, 1872, "in comprehending, noting, and defining this course [of disease] and its stages, and interpreting the precise degree and incidence of the inner development of the process, and measuring its effect, that the great triumph of modern medicine consists." Hence expectation is aroused; fulfilment should not be too long deferred.

"Since the publication of Sir John Forbes's book," says Dr. Johnson in his Address in Medicine before the British Medical Association in August last, "and partly, no doubt, in consequence of that publication, our views as to disease and its treatment have undergone a very great change. A purely expectant treatment is now as common as then it was rare. It is now fashionable and orthodox to trust to the curative powers of Nature, and to doubt the therapeutic power of Art. The pendulum has swung from one extreme to the other." To the young men of the Profession this announcement from an influential observer offers unusual assurances. The obstacles in the way of their fathers-in-medicine need no longer to greatly impede their progress. Let them avail themselves of present opportunities while they can. "Life is short, opportunity fleeting," said the great Master; pendulums do not tarry long in an extreme. While it is "fashionable and orthodox," since

every one instinctively conforms in some degree to the tendencies of his time, let them strive unceasingly to solve for themselves and others, *my first question*,—that they may have in the solution a surer basis for their faith in their Art, and thus become better guides to the sick than their predecessors.

As for the still often-expressed fear that individual success would be ruined, and the Profession reduced to a nullity, should such investigations become general, nothing can be more groundless.

In all ages, and in all countries, the most successful, the most confided in, and ultimately the most honoured, have been those who, with no obnoxious pretensions to personal superiority, have been guided more thoroughly than others by Nature itself in their care of the sick. Of the truth of this, the late recipients of royal favour and a nation's gratitude, in old opinionated Fatherland, are notable examples. Personal success depends upon far other qualifications than ability to deal out nostrums and specifics. To be eminently successful, say our teachers, and their words are worthy of all acceptance, requires, in addition to adequate learning and science,—the kindness of heart and manner of a gentleman, to put one spontaneously in the place of the sufferer, however humble, that he may be done for as one would wish in like circumstances to be done by,—balance of character,—steadiness of purpose,—uncomplaining patience,—self denial,—rectitude,—sagacity,—sympathy, with firmness capable of assuming the expression of inflexible sternness,—a certain amount of personal experience and responsibility conjoined with the talent for comprehending and applying its results (a). These, according to our teachers, are some of the requisites for personal success. Whoever has these need not fear a loss of occupation. That there are such in our Society, such in the State, such in all countries, admits no shadow of doubt; and they are they who, in the exigencies of individuals and of the State, will be sought out and chiefly depended upon.

The Medical Profession is essential to every community; henceforth no civilised people can possibly do without it. Were any or all of the drugs in popular repute proved to be useless; were it even found that there is no particular medicinal agent essential to the best treatment of disease, of which, however, there is not the slightest apprehension, the value of the Profession, as such, would not be diminished, nor would it become, as one reviewer has coarsely expressed it, "just about good for nothing." It has, as we have before and frequently intimated, higher and nobler purposes. Never in the memory of the oldest was less medicine given than at the present day, and never was the Profession, the truly regular and scientific portion of it, held in higher regard by the people. Said a commoner within hearing a day or two ago, "there is a great deal of real respect for educated physicians everywhere. After all, they are the best and most substantial men we have. In country towns they are invaluable."

The Profession which has members with the qualifications and influence we have described may well endure the insolence of scoffers, the gibes of the thoughtless, and the fears of pusillanimous friends, for, akin to sacred teaching, no human employment confers a greater good upon the race, or is in fact more truly valued by mankind. It is deeply grounded in the necessities of human nature, and cannot be undermined; but its usefulness will be vastly increased, and placed on firmest foundations, and it will be held in still higher estimation when it shall have added to its already great and varied acquisitions a full solution to *my first question*.

Literature.

THE FALLACIES OF TEETOTALISM (b).

THE object of the writer of this volume is to oppose the introduction into England of a liquor law resembling that adopted by the State of Maine. The objection to such a law is that the opinion of minorities is disregarded,

(a) This last clause is from Sir Henry Holland's "Recollections of Past Life." The other "requirements" are from various sources not needing special acknowledgment.

(b) "The Fallacies of Teetotalism, or the Duty of the Legislature in Dealing with Personal Freedom, &c." By Robert Ward, Editor of the *North of England Advertiser*. London: Simpkin, Marshall & Co.

and this, according to some of the most distinguished thinkers of the day, is an injustice that mars our representative system. We have no desire to see such a law instituted, but think it needless that a good argument should be weakened by mere personalities against a leader of the Alliance Society, such as, for example, by telling him to "shrink into his natural insignificance," by speaking of his "insolent conceit," and by bidding him, in metaphor more forcible than elegant, "stand naked on a pedestal." We regret that the Alliance should wish to push forward legal measures to prevent the sale of alcohol, but we do not wish the author of the volume before us wholly despise that Society. We consider that the true strength of such a society consists in passive expression of opinion, and in its supporters not endeavouring to make converts, and in its funds being limited to the small amount necessary to pay for rooms for its members to meet in and similar trifling expenses.

Mr. Ward's claims on behalf of alcohol are rather one-sided. We dispute that "it is the business of the publican to rouse up all the faculties of the mind, and that if a man's mind contains within it any spark of generosity a little alcohol is the most likely thing to arouse it into action;" unfortunately the stirring thus advised so often brings to the surface other qualities which more than counterbalance the vinous generosity. Again, in saying that courtships and marriages have often owed a felicitous end to a cheering glass of wine, we are reminded that many a slight difference has owed its seriousness to the same stimulant.

When the writer seeks his arguments from Biblical lore he falls into the same pit as his opponents by laying great weight, contrary to the expectations of the writers, on the literal meaning of passages abounding in oriental imagery.

When Judith fascinates Holofernes, makes him drunk, and murders him, we protest against this quotation to show that drink is admirable. We substitute the pure morality of Christianity, and say that Judith's conduct was diabolical.

The fallacies of teetotalism are opposed in Mr. Ward's book by a questionable argument when he says that as carbon, hydrogen, and oxygen are constituents of alcohol, and as these substances are also contained in the body, therefore alcohol is a nutritive power. Many of the poisons contain simply carbon, hydrogen, and oxygen, yet these could hardly be described as nutritious.

Again, some of the historical arguments are somewhat forced. So far from agreeing with Mr. Ward that the fall of the Aztec and Red Indian races was due to the avoidance of alcohol, we feel inclined to believe that the fall of the majority of the tribes may be attributed to their love for "fire-water." The section of Mr. Ward's book that affords most interest is, that giving an account of the working of the liquor law in Maine, where it seems that the law is systematically evaded, as in Scotland are the regulations for closing public-houses on Sunday.

COOLEY'S CYCLOPÆDIA OF PRACTICAL RECEIPTS AND COLLATERAL INFORMATION (a)

THIS excellent old friend appears more portly than ever, and yet sounder in constitution. It is certainly cyclopædic to find Jam, Jaundice, Japanning, Jathrophic, Jasper, and Jelly on one page.

The peculiarities of this edition as mentioned by the editor in the preface are, that in the chemical portion it has been corrected to the present state of our knowledge, except in matters of a purely scientific interest, which have been expunged. The Indian and United States Pharmacopœias have been added. All the articles on excisable or duty-bearing commodities have been in this volume re-written by Mr. Harkness, of the Inland Revenue. But this description fails in conveying the

(a) "Cooley's Cyclopædia of Practical Receipts and Collateral Information." Fifth Edition. Revised and partly re-written by E. Tison, F.C.S. London: J. and A. Churchill. 1872.

value of this edition to those who possess the old work. As previously stated, it is written up to the chemistry of the day and with every amount of care. It has evidently not only passed through the hands of a practical man, but one whose knowledge is based upon sound scientific attainments. We think the excision and curtailment of the articles on the recognition and treatment of disease was judicious and might be even more thoroughly carried out. The editor says, "the length and number of the articles on the recognition and treatment of disease have been reduced, as it was thought that those of previous editions might, in many instances, be productive of more harm than benefit to those for whom such information was compiled—namely, emigrants and others not within the reach of the surgeon or physician. In a cyclopædia of receipts the valid excuse for the insertion of such matter would be for the "treatment of each disease" and the insertion of popular remedies. How impracticable is it to carry this properly out. We will notice in passing one small mistake which, slight as it is, might in the hands of a tyro lead to an accident. Under the head of "water" is given the "formula for Nesler's test for ammonia," in which it reads: "filter and add to the filter 2,000 grains of potassium, &c." Now the addition of 2,000 grains of potassium to water would be rather striking, and the typographical error would be seen at once by any but a chemist of the most limited experience. To illustrate the fulness of this work we may notice that under the head of pills alone we find between 400 and 500 formulæ.

Correspondence.

MEDICINE AND MEDICINE MEN.—A MIDNIGHT ESSAY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—“Twice does he live who can enjoy the remembrance of the past,” constitutes the frequent apology for rushing into print, and here the opportunity occurs of suggesting to the beginner to illustrate and lighten composition by utilising the brains of others, until the trained author can fly alone; when, choosing new phrases, coining quaint similes, he may abandon the crutch and kick aside the ladder of quotation. A stilted, jerky, disconnected style, difficult to change, requires time to correct; a great art also lies in excluding, or, at all events, concealing egotism. “Sir, you have but two topics—yourself and me—I am sick of both,” said Dr. Johnson. Yet the task is one of pleasure to take up the pen according to humour, dotting down ideas momentarily uppermost, and to lay the paper aside when the fit is over. This is Monday night. An aged primipara has been in labour since Saturday. I hate midwifery, but resembling the gentleman from Galway, who paid the rent by eating rats at country fairs, one must live, and a tight fit it is when one's taste, Harold Skimpole fashion, inclines to truffles and champagne. However, the os rigid, undilatable, the pains vigorous, a fair amount of room, but an ugly look about the eye, coated tongue, convulsive movements, irregular pulse, all attract attention; chloroform and tartar emetic no good; ipecacuanha tried. In the meantime writing this letter will pass an hour, just as Fosco in the midst of trouble could trifle with bonbons and canaries.

People out of the Profession, indeed many in it, whose lines have been cast in pleasant places, simply watching the wreck from the shore, little imagine the sorrows of the struggling doctor in failing health, with an expensive weakly family ever tugging at the purse strings. Once full of zeal, hope, and vigour, now he lags behind. Younger men creep ahead. Where formerly he attended the master the servant is visited. Without energy or opportunity to study the ever changing ideas of the day, and considered simply one of the old school, patients begin to doubt, to lose confidence, perhaps to dabble in homœopathy, or an obscure injury about the hip-joint involves an action for malpraxis. The stab inflicted by a colleague, bitterly does he cry—Et tu, Brute! Suddenly comes the end—worsted in the conflict, the poor fellow lays

down his weary head free at last from vexation and worry, no more heartbreaking, hopeless battles with loathsome diseases amidst dirt, destitution, and sad faces, no more insults from the vestry, no more bodily pain, for the Christian practitioner awakes in the happy hunting ground at length rewarded. How about his family? (A Medical man to get practice is obliged to marry—the clergyman, the author, or the lawyer need not.) What money did he leave behind? Not a sixpence! The sound investment turned out a rotten swindle, the insurance company failed, and before the chance occurred of recuperation the lamp was extinguished, the curtain fell. Butchers, bakers, publicans also die.

“Underneath, in hopes of Sion,
Lies the landlord of the Lion;
Submissive to the heavenly will,
The son keeps on the business still.”

Mark the last line—before the doctor is buried the practice has been greedily snapped up. As the shark, tormented by parasites, is always hungry, other Medical men, what with eager competition and the ruinous cost of living, must think of themselves; Patients also, and why should they remember the family of the man who shortened his life by lengthening theirs? He was paid for it; at all events, sent in his bill. Jefferson tells us about fees in former days. Sir Astley Cooper netted five guineas the first year, twenty-six the second, £400 in the seventh, eventually his income rose to £21,000; Meade earned £7,000; Atkins received £6,000 for attending a sick child, afterwards Charles the First; the physician who attended Queen Caroline received 500, the surgeons 300 guineas each. Dr. Dimsdale, who went over to Russia and inoculated the Empress and her son in 1763, received a fee of £12,000, a pension for life of £500, and the rank of Baron of the Empire; too, we read of a physician who, losing two ladies of quality, his income fell from £3,000 to £300. In those days medicine was in its infancy, and Don Quixote was suggested by a cynical, doubting genius as the best text-book. What would he think now of “Aitken's Medicina,” “Druitt's Surgery,” or “Parkes' Hygiene?” Two miles down in the bosom of the deep, resting on soft sand, amidst the debris of shells, where all is calm, where the most minute organism cannot exist, the Atlantic cable flashing the news of Livingstone's safety and information generally, sometimes becomes silent. Yet the eye of science penetrating the blue waves can see the point of injury which skill and perseverance can repair. In a minor degree of comparison the modern physician, what with books, appliances, reagents, &c., can look into the brain, the throat, the kidneys, the uterus, and other organs. Thanks to the much abused specialist, instead of throwing clubs about in the dark, he pounces down on the spot where the smouldering flame of destruction insidiously is going on. Yet, stripped of its high calling, glory, and interest, no one can deny that our information is gained by the disgusting dissection of the dead, by sickening operations on the living, and by the examination of filthy excretions from various sources. We wring secrets also at the infectious bedside of malignant fevers in dens and garrets, and returning home jaded and tired we are afraid to kiss our children when they cluster round to wish us good night. Having stated the case, the inadequate payment for priceless services, what is the remedy? Surely the labourer is worthy of his hire; we are but human beings anxious to do the best, and to benefit others, but we like to have a roof over head, to keep the wolf from the door, and to leave some provision for our widows and orphans. Let us wage war against cheap doctoring in every shape, clubs, dispensaries, miscellaneous out-patient attendance, as well as cheap Medical schools, the forcing-beds of men whose birth, sphere, and tastes incline behind the counter, men who at one moment would give advice about pneumonia, and at the next be ready to sell photographs and hair-oil. Instead of waiting until Christmas, when the other bills pour vexatiously in, the account should be sent in when the gratitude is red-hot. There should be an organised fund to prosecute quacks, herbalists, practising chemists, and unqualified practitioners. Young lads about to enter should pause to consider the overstocked condition of the Profession, how many dogs to the bone, and the difficulties to be surmounted.

Thank God the case has ended, mother and child doing well, the glorious sun plays on the haggard faces of those who have been up all night, the birds welcome another day, and as each day has its appointed duties, a bath and shave will be the only rest for

Your obedient servant,
A FELLOW OF THE ROYAL MED. CHIR. SOCIETY.

THE PUBLIC SERVICES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—To the Students' Number of the MEDICAL PRESS which I observe to be issued next week, and which is the preface to the opening session, it might appropriately belong to exhibit the relative positions of the public Medical services, and the exact market conditions of the three Medical departments.

The proportionate competition of members of the three countries is an indisputable criterion of the general estimate of each service, and if it should appear that one service is monopolised by the students of one nation it must follow either that these candidates are superior to all comers, or that the appointments are deemed valueless by the others. Judged by this test it will be found that the Indian Medical Service is by far the most acceptable to all students of the United Kingdom, that the Naval also can draw competitors from the three countries, but that the Army Medical Department is left entirely to the use of the Irish.

At the last examination for the Indian Service, in February, 1872, the nationalities of the 40 successful competitors were as follows:—15 Irish, 14 English, and 11 Scotch. At the last examination for the Naval Service in the same month, out of 17 accepted candidates, 10 were Irish, 4 Scotch, and 3 English, while at the same time, of 12 admissions into the Army Medical Department, 10 were Irish, 1 English, and 1 Scotch.

It behoves the Irish students, therefore, to consider whether in seizing on the appointments which are spurned by the other divisions of the empire, they are not betraying themselves into positions of which they may in after life sorely repent; and also to reflect that in filling these rival-less vacancies, they are inflicting grievous hardships on those who had entered under fairer prospects, and who, now in the time of disappointment, appeal to them to secure the concession of justice by joining their Scotch and English brethren in the rejection of such treacherous appointments.

Omitting all minor details, the disadvantage of this service can be made intelligible to all by stating that, while promotion to the rank of surgeon can be obtained in the Indian and Naval services in twelve years, the senior "assistants" of the army have now entered on their 16th year of service, that only nine promotions have been made during the present year, and that twenty-six assistant-surgeons still remain who joined in the year 1857, and ninety-seven in 1858, making it perfectly evident that many of those of the latter year must complete twenty years in the menial capacity of "assistants." In conclusion, no better advice can be given than that offered by the MEDICAL PRESS AND CIRCULAR, April 10th, 1872—"It will, therefore, be well for future candidates for the commissions of assistant-surgeons to weigh well if the play be worth the candle-light. *We would say certainly not, if something be not done to open the way for more rapid promotion.*" And also by the *Lancet*, March 16th, 1872—"We venture to think that young Medical men too, will, by-and-bye, find out that they had better not enter into any engagement with the present War Office."

I am, Sir, yours, &c.,
MILITARIS.

SPECIAL CORRESPONDENCE.

VACATION NOTES.

BY C. R. DRYSDALE, M.D., M.R.C.P.L., F.R.C.S.

PARIS, August 12th, 1872.

SIR,—Many able men in the Medical Profession are accustomed entirely to throw aside all thoughts of Professional subjects for a short time every year, and to endeavour to recruit their energies by a short fallow. Perhaps they are right in so doing; but in the few lines which follow, I will, with your permission, narrate what I have lately seen during a week or two of absence from London. Passing through Margate, on my way to the Continent, I took the opportunity of visiting the renowned Margate "National Sea-bathing Infirmary," and found it a most healthily situated hospital, close to the shore, a little way out of that most salubrious of London sea-bathing places, Margate. There are about 250 patients in the

wards at present, 150 of whom are children under the age, I think, of 16, and 100 are adults. They seemed to me all to be suffering from some form of scrofulous disease, either hip-joint disease, or disease of the bones and glandular system. Among the children, I was not able to detect any one with the peculiarities of teeth caused by inherited syphilis; so that, I presume, such cases are not very common here. The children bathe in the sea twice a week in summer, having a bathing machine of their own at their service. The Infirmary is two stories high, and the female patients have possession of the wing facing the sea, the males being further from it.

The children pay some five shillings a week for their board, which, of course, makes the hospital, after all, not a truly national one, in the sense that the French would use that word; but as the hospital is supported by voluntary subscriptions from good-hearted people, we can hardly "look the gift-horse in the mouth." Some two years ago, it may be in the recollection of your readers that I gave a description of a very large hospital at Berk-sur-Mer here in France, built by the late Empress Eugenie's orders, and maintained still by the "Assistance Publique" of Paris. There was a great contrast between the comforts of the little hospital at Margate, with its well-clad and respectable-looking patients, and those I remember to have seen at Berk, where the patients reminded me of the scholars at that classical academy "Do-the-Boys-Hall near Greta Bridge, Yorkshire," so wan and pallid did they look. Yet, when I remember that the scrofulous children of Berk were sent from the poorest quarters of Paris, Amiens, and other hives of industry, at the expense of the cities sending them, I am not sure that the Margate Infirmary can compete with the Berk hospital in real national utility. At any rate, we want in England a hospital where the scrofulous poor of our unfortunate over-grown cities could be sent, to grow up with some chance of enjoying a happy existence.

By the way, Margate is a particularly healthy sea-bathing place; and for invalids, much preferable to Ramsgate or Southend. The soil seems very dry and the sea-breezes admirably fresh on the new pier. I should say decidedly to Londoners wanting fresh air and health, "go to Margate." Ramsgate has better sands, but is too much of a town to be tranquil enough for invalids who live in London. Deal is a pleasant place, and has also an agreeable pier; it is, I should say, remarkably healthy. Dover is quite detestable as a health resort; but Folkestone is a delightful sea-bathing town, and much has been done during the last five years to make it attractive as well as eminently salubrious. It seems to have a very low death-rate. Boulogne has also been much brushed up, and is no longer the quaint ramshackle town I remember it some ten years ago. Still, with all that, the excellent Medical man who was, and perhaps still is, Maire, has done to cleanse the bed of the river at low tide, by damming up the small stream, the Liane, and allowing its water suddenly to pour down in a rapid stream into the empty river bed, Boulogne is still, in my opinion, not a desirable residence for an invalid. The bathing, however, is quite admirable and "laisse rien à désirer." It is a wonderfully gay and bright place in comparison with our sober English provincial towns; and for persons who are not invalids, and are lodged far away from the port, it is a most pleasant and attractive residence, as, indeed, our compatriots recognise, as the English element is very strong in Boulogne.

In a flying visit to Paris for a few days I had a rather rare opportunity of visiting the Maternité, or hospital for accouchements, as it is situated next door to the Hôpital du Midi, and my kind friend Dr. C. Mauriac was attending some of the patients in the Maternité, who had fallen sick after delivery, together with one or two of the young lady-students in the hospital. As we have no similar institution to this in London (and as I am one of those who believe that the education of women in medicine is one of the noblest movements of the day), I may

be allowed, perhaps, to give you some details of the Maternité Hospital, and what I saw and heard in it. The hospital is a large building with some ten acres, perhaps, of ground attached to it, all enclosed within lofty walls, and adjoining the Observatoire, the Hôpital du Midi, and the Hôpital Cochin. There are now-a-days only some sixty women taken into the wards, since the admirable works of Lefort and others pointed out the great danger of packing lying-in-women into such hospitals; and consequently, there are scarcely ever any cases of epidemics heard of now. The accouchements are attended to by Madame Calé, the "sage-femme" in chief, and by the pupils, some eighty in number, most of whom are sent up from the provinces to study in the hospital. Dr. Tarnier is the physician accoucheur, and visits the hospital daily. There is also an *interne*. The students study Cazeaux, edited by Tarnier.

The Ecole d'Accouchement, or Maternité, is designed to form sage-femmes of the first class for the whole of France. The students, most of them young ladies under twenty, learn in this school from Dr. Tarnier and Madame Calé, the theory and practice of midwifery. Vaccination and the care of children is taught by Madame Calé and by the *interne*, who also teaches dressing and the art of bleeding (which in England, I presume, would be considered as needless); and the apothecary of a neighbouring hospital lectures them daily upon the elements of botany, natural history, and pharmacy. As the pupils are not allowed outside of the precincts of the hospital, they have a botanical garden, a druggist's shop, and a museum all for themselves within the walls. Persons are admitted as students between the age of twenty and thirty-five, upon showing that they know how to read, write, and spell *correctly*, and upon production of those mysterious papers which the French are so fond of, their certificate of birth, of marriage or widowhood, and of good life and morals, given by the Maire of the town they come from. They have further to show that they have been vaccinated, or had the small-pox. They must not enter before the 1st of July, nor after the first ten days of this month have elapsed. Examinations, reception, and distribution of prizes take place only at the end of June.

During the year of residence the pupils are only allowed to leave the hospital six times with their fathers and mothers, or husbands, or with persons expressly pointed out by these. No pregnant woman can be admitted as a student. The price of pension or board, including instruction and food, is 600 francs, or £24, payable quarterly in advance, and 36 francs additional is charged for washing. The price of books is 42 francs, and of instruments 19-75 francs; making a total of only £27 18s. 6d. for one year of an education which is very practical and thorough, as far as it goes.

Dr. C. Mauriac showed me the lecture-room where Madame Calé was lecturing to the students, and where were inscribed the names of Madame Lachapelle, along with those of Bandelouque, Dubois, and others; and I was shown by one of the young pupil sage-femmes the druggist's shop, the anatomical figures and plates, and other means of instruction afforded by this most admirable institution for the daughters of France.

There is, in addition to the Maternité Hospital, a school for midwifery for women at the Hôpital des Cliniques, where there are also some fifty students of all ages; but, in this case, the students live where they like and have nothing at all to pay for the instruction they get, which is confined entirely to midwifery. It is chiefly frequented by students who live at home in Paris, and the only qualification for attending these classes is a knowledge of spelling, reading, and writing French. The students are thus not so well instructed as in the Maternité, but it suits the means and tastes of many better than that more conventual style of education. Each pupil remains one night and a day a week in the hospital, in attendance on cases in the wards, and passes the rest of the week at home. After passing a year at either of these hospitals, the sage-femmes are allowed to compete for medals, and

are allowed to come up for examination and pay some £4 16s. for their diplomas of Sage-Femmes. As I know well the miserably unprovided state of many of our country districts, in the matter of medical assistance in labours, I am convinced that if there were many women in Britain as well taught in midwifery as these ladies are, almost all the simpler cases of midwifery would fall to their care. Besides, this is the opinion of one of the ablest men of the Obstetrical Society of London given to me orally.

This year all seems going on very quietly in the medical world in Paris, and I think there is a relief in the minds of all to have got rid of the *tyran*, as a medical friend tells me N. III. was called in Paris.

The Midi, which suffered from a bomb during the bombardment, has been repaired, and is quite full of cases as usual, notwithstanding the much praised inspection of prostitutes in Paris. M. Mauriac tells me that he too is beginning to be rather sceptical as to the great virtues of mercury in syphilis, since it does not seem to prevent the appearance of eruptions, or, indeed, in many instances, much influence the course of the disease. But then, as he truly adds, it is given as a matter of routine and faith; and it is most troublesome to make the long comparison of cases with and without mercury, requisite for coming to a definite conclusion as to the real value of this drug. He gives iodide of potassium in large doses of fifteen grains, or one gramme thrice or four times a day; and has noticed a good number of cases of precocious periostitis, which makes him doubt of the value of the dictum of M. Ricord, that syphilis is so regular in its course. In this I agree with him, for I have found iodide of potassium useful in all stages of the disease if given in its dose of fifteen grains. Dr. Mauriac is publishing some interesting cases of early syphilitic periostitis in the *Gazette des Hôpitaux* at present. Dr. Alfred Pournier's lectures, delivered at the Lourcine, are in the press at present, and will be published in two months or so.

One thing that pleased me in Paris this year was, to hear less about soldiers and powder and bullets than usual. Much as I respect the profession of a defender of his country, there is something afflicting to the medical mind, I conceive, in the sight of so many persons, as one usually was in France, devoted to the destruction, and not the curing of their fellows. Many medical men here seem to think that diplomacy may perchance restore Alsace to France without the horrors of another war like the last, which made all civilised nations shudder; and I cannot help thinking that the philosophy of Voltaire and others of the school of Cordoret, Taine, and Comte, may soon prevail, and make this noble country less easily guided by a mixture of military adventurers and Jesuits. The admission of our great *confrère* Littré into the Academy is a step in the right direction, and coinciding with the ascendancy of J. S. Mill, Bain, and H. Spencer with us, makes me hope much for the future of England and France. The philosophy of Germany, I fear, is far too transcendental to lead to happiness at present. As yet, I do not find the prices of the necessaries of life much risen in Paris, on account of the taxation necessary to pay the interest of the war debt, so that the condition of the working-classes is not bad, and I was only once asked for charity in a week in Paris. The smallness of the families strikes me every year more and more; and it is evident to me, at least, that, so long as the Parisian work-people are so prudent as to their numbers, and so artistic as they are made by the admirable schools of art here established, Paris will always be the city of Europe where the working-classes will have the greatest enjoyment and dignity.

A good deal has been said about the hospitals of England and France; and certainly the London hospitals are much cleaner and healthier than those here. For instance, I visited Bethlehem Hospital shortly before leaving home, and found everything there on a most magnificent scale, and the poor patients treated quite like ladies and gentlemen. This was a great contrast to the homeliness of La Salpêtrière, as I remember it some years ago on a

visit. But, then, the expenses of Bedlam are very great indeed for the number of patients taken in; and the class of cases is evidently derived from the "respectable" classes, whereas Salpêtrières is the property of the whole French people; and administered with strict economy, by the Assistance Publique, whilst Bethlehem is looked after, I think, by some of the magnates of the City of London, and I have seen too much of London charities not to know what an immense waste goes on in all managed by that venerable but rather grotesque body, the Lord Mayor and Corporation. If Bethlehem Hospital were in Paris, I should suppose the expense of maintaining its 300 patients would not be more than half of what it now is. Still, there is, to the uninitiated something truly delightful in the cleanliness of English as compared with French hospitals; and, no doubt, the former people have a far greater love of soap and water and scrubbing-brushes than the latter. The true comparison, however, lies between the Parisian hospitals and our workhouses, for in Paris the workhouse does not exist, so that when people are very poor there, they fall sick and get into the hospital, especially in winter.

Medical News.

Apothecaries' Hall of England.—At a Court of Examiners held on Thursday, the 5th inst., the following gentlemen, having passed the necessary examinations, received the L.S.A., viz., Messrs. Fred. William Barron, of Peterborough (St. Bartholomew's Hospital); Douglas William Gifford, of Guernsey (St. Bartholomew's Hospital); William Rutherford, of Ballinasloe (Dublin School of Medicine); and John Francis Staines, of Southampton row (London Hospital). At the same court Messrs. Henry Evans, of Guy's Hospital, and Henry Jackson, of the Middlesex Hospital, passed the primary Professional examination.

Glasgow Medico-Chirurgical Society.—At the last meeting of this society the following gentlemen were elected office bearers for the Session 1872-3, viz:—*President*, Dr. Robert Scott Orr. *Vice-Presidents*, Dr. Geo. Buchanan, Dr. Andrew Fergus. *Council*, Dr. James Gray, Mr. Robert Grieve, Mr. J. Pollock, Mearns, Dr. R. Renfrew, Dr. George Miller, Dr. T. D. Buchanan, Dr. R. Stewart, Coatbrg., Dr. James Scanlan. *Secretaries*, Dr. Robert Perry, Dr. Alex. Robertson. *Treasurer*, Dr. H. R. Howatt.

NOTICES TO CORRESPONDENTS.

THE Editor of the IRISH MEDICAL DIRECTORY will be glad to receive, and, if possible, to carry into effect in the forthcoming issue of the DIRECTORY, any suggestions for new matter, or emendations in the old. The Editor will add to the DIRECTORY any information which may appear to be interesting or useful to even a small section of the Profession in Ireland; and he solicits from the readers of the DIRECTORY their advice on the subject.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this request.

All communications intended for insertion must bear the name and address of the writer; not necessarily for publication, but as a voucher of good faith.

Rejected MS. will always be returned, if a request be received from the author, within one week after the article or letter has been declined.

SUBSCRIPTIONS IN THE UNITED STATES.—A correspondent has drawn our attention to the fact, that some of the houses in the United States are charging the enormous figure of 15 dollars per annum (more than £3) for supplying this Journal to different parts of the States. We beg, therefore, to state that we shall be happy to supply the same regularly post free per annum, if paid in advance, for considerably less than half this amount, viz., six and-a-half dollars (about £1 8s. 0d.), either direct from our offices in this country, or through our recognised agents in the United States.

Ms. J. W. D., Gosport, will receive an answer to his inquiry in a day or two.

Dr. F. P.—The stamps were not enclosed as stated.
L. E. R.—It is an unseemly and undignified proceeding, and is unfortunately not of rare occurrence. You will find a similar case adverted to in another column.

THE NEW LAW ON ADULTERATIONS.—As there seems to be a doubt existing in the mind of many as to the actual purport of this Act, and in reply to one or two correspondents, we give the following particulars:—The law now is, that every person who shall wilfully admix, and every person who shall order any other person to admix, with any article of food, or drink, any injurious or poisonous ingredient or material to adulterate the same; and every person who shall wilfully admix, and every person who shall order any person to admix any ingredient or material with any drug to adulterate the same, shall, for the first offence, pay a penalty not exceeding £30, and for the second offence shall be guilty of a misdemeanour, and be imprisoned for a period not exceeding six calendar months. The penalty on a person selling articles of food, or drink, or drugs, which they know to have been adulterated, to be not exceeding £20 and to pay costs; and if any person so convicted shall afterwards commit the like offence, the justices shall cause such offender's name, place of abode, and offence, to be published, at the expense of such offender, in such newspaper, or in such manner, as to the said justices shall seem desirable. Any person who shall sell any article of food or drink, or any drug, knowing the same to have been mixed with any other substance, with intent fraudulently to increase its weight or bulk; and who shall not declare such admixture to any purchaser thereof before delivering the same, and no other, shall be deemed to have sold an adulterated article of food, or drink, or drug, as the case may be, under this Act. The Pharmacy Act, 1868, is to be incorporated with the present statute. Analysts are to be appointed at various places, and inspectors of nuisances may submit articles of food to be analysed. The analysts appointed are to make reports quarterly to the local authorities. Proof is to be given of the identity of the articles submitted to analysts. A purchaser in any place where there is an analyst appointed under this Act, may require the same to be analysed. The articles of food, &c., ordered for analysts are to be received, and samples retained by the inspectors. The expense of executing this Act shall be borne in counties out of the county rate, or out of the grand jury cess in Ireland; and in boroughs out of the borough fund, and in Scotland out of the police money in counties and boroughs respectively. The Act is not to affect the power of proceeding by indictment or to take away any other remedy against any offender under the Act.

VACANCIES.

Parish of St. George, London, W. Medical Officer of Health. Salary £350 per annum. (See adv.)
Limerick Union. Annacotty Dispensary District. Medical Officer. Salary £100, exclusive of fees. (See adv.)
Salford Hospital. District Surgeon, to visit patients at their homes. Salary £80 per annum.
Lancaster Infirmary. House-Surgeon. Salary £100 per annum.
Tunbridge Wells Dispensary. House-Surgeon. Salary £90.
Evesham Union, Worcestershire. Two Medical Officers. One for the Workhouse. Salary £30, with extra fees. One for the District. Salary £53, with fees extra.
Alderbury Union, Salisbury. Medical Officer for District No. 3, at a salary of £120 per annum.
Tiverton Infirmary. House-Surgeon. Salary £80, with residence.

APPOINTMENTS.

Cox, E., M.R.C.S.E., Medical Officer for District No. 5 of the Barnstaple Union.
DURHAM, A. E., F.R.C.S.E., Surgeon to Guy's Hospital.
ERSKINE, W., M.D., Medical Officer for Cullross, Perthshire.
GIVEN, G. K., M.D. Qu. Univ., L.R.C.P. Edin., Medical Officer to the Gortin Infirmary Workhouse and Dispensary, co. Tyrone.
HUGHES, A. C., F.R.C.S.I., Surgeon to the Stanley Hospital, Liverpool.
KEMPTHORNE, J., L.R.C.P.L., F.R.C.S.E., Medical Officer for the Callington or No. 7 District of the Lakeard Union, Cornwall.
LITTLE, W., M.D., L.R.C.P. Ed., M.R.C.S., Surgeon-Accoucheur to the Toxteth Park Lying-in Charity, Liverpool.
LLOYD, S., M.R.C.S.E., Medical Officer for the Leigh or No. 4 District of the Martley Union, Worcestershire.
LOWSON, D. F., M.B., C.M., Resident Medical Officer to the General Hospital and Dispensary for Sick Children, Manchester.
PARKER, R., M.B., B.Sc., Physician to the Stanley Hospital, Liverpool.
RICHARDS, W. A., M.D., L.R.C.P.L., M.R.C.S., Assistant-Physician to the County Hospital, Winchester.
SHARPE, A., M.D., Assistant Visiting Surgeon for Woolwich under the provisions of the Contagious Diseases Acts (Women).
TUDGE, J. M.D., M.R.C.S.E., Resident Medical Officer to the Westminster General Dispensary, Gerrard Street, Soho.

The Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 18, 1872.

STUDENTS' NUMBER.

STUDENTS' NUMBERS have now become annual necessities, not only for those about entering Medical Schools, or the Profession, but also to keep those who are already in its ranks *au courant* with every change of regulation—official or otherwise—Professorship successions, &c. To do this briefly and at the same time attractively, it seems to us that the most practical information as to the method of Medical education and the future disposal of the Student is required of us, rather than prolix official regulations, which, when desired, are always at command. We have, therefore, accorded to such matter the smallest possible space consistent with clearness, confining our erasures as much as possible to technical redundancies, and omitting nothing which seemed of the least importance.

Into the space which this epitomising has given us, we have endeavoured to compress as much practical, every-day information as we conceive to be necessary, and writing as we do for the Students of the United Kingdom, we have endeavoured to give predominance to the educational arrangements of no special locality.

As we have, with the view of economising the space at our disposal, dispensed with all details which are contained in the advertisements of the various Medico-Educational Institutions, we beg to refer our readers to the advertisement of each in connection with which the editorial information should be read. Our duty has been to supplement these announcements by information of an unofficial character, and our readers will thus, we trust, be put in possession of a complete *vade mecum* of the method and means of Medical Education.

THE TEACHING OF PRACTICAL PHYSIOLOGY.

ONE of the most important changes in the curriculum of the Medical student is that lately brought about by the determination of the examining boards to require proof of instruction in Practical Physiology. We have on former occasions referred to the provisions made by some schools in order to comply with the new requirements. We this week lay before those concerned the arrangements made at the great East-end College, that of the London Hospital, and are glad to be able to report so favourably. As the matter is of the very highest moment we shall probably, as opportunities occur, report on the provisions of other schools in this respect.

At the London Hospital the instruction is given in an able manner by Dr. Fenwick, Physician to the Hospital, and formerly Lecturer on Pathology in the University of Durham, and Dr. Bathurst Woodman, Physician to the Hospital; assisted by the indefatigable demonstrator, Mr. J. Needham, F.R.M.S. The course occupies two winter sessions, of 100 lectures each, fifty of which are devoted to theoretical, and the remainder to practical instruction.

The theoretical or systematic physiology is taught by lectures twice a week in the anatomical theatre, where the tables, at which the students are seated, are so arranged that specimens (placed under the microscope) illustrating the histological points of the lecture, can be passed round without the slightest inconvenience or noise.

Histology or practical physiology is taught in the histological laboratory by demonstrations twice weekly, Wednesday and Saturday; those on Wednesdays being given alternately by the lecturers, and those on Saturdays by the demonstrator.

The instruction given on Wednesdays is principally for first year's students, and, therefore, of rather an elementary character. In these classes the student is required to make himself thoroughly acquainted with the microscope and its uses; also to familiarise himself with the appearances of fresh and preserved tissues. Each has placed

before him a set of reagents in drop-bottles, and is required to provide for his own use—glass slips, 3 in. by 1 in., thin-circular-covering glass, a pair of fine scissors, a pair of fine forceps, a razor, and two needles in holders. The more expensive instruments are provided by the college, and lent when necessary.

The Saturday demonstrations are of an advanced and thoroughly practical nature. The students of this class (who are required to attend the Wednesday demonstrations for one session previous to being admitted) are taught not only human but comparative histology. They are instructed on the latest and most approved methods of investigation, also in putting up preparations permanently for the formation of a collection of microscopical objects. The necessity of this comes to us with greater force, when, on referring to so great an authority as Kölliker, we find as follows:—"A collection of microscopical preparations is indispensably necessary for a more exact study of histology." (Sydenham Society Trans., p. 7.) During the demonstrations the more difficult and costly preparations, such as many injections, sections of bone and teeth, &c., are sent round for inspection.

Physiological chemistry is given in Dr. Letheby's practical chemistry class, which is held in the summer session, and consists principally of the qualitative analysis of urine, blood, bile, &c., &c.

There are twenty-six microscopes by R. and J. Beck, and Crouch, the objectives being $\frac{1}{4}$ in. and 1 in. by Beck, and 1.5 in. by Crouch. The oculars, A and B of Beck, and A of Crouch. Other instruments and apparatus are numerous. The student is encouraged to bring his own microscope; should he not do so, an instrument is lent by the college, for the use of which (during the session) a fee of half-a-guinea is charged. The material and all chemicals that can possibly be required are provided by the college.

The histological laboratory is a large, well-ventilated room, beautifully illuminated by ordinary side windows

and sky-lights. In it there are four large tables, each containing ten drawers, one of which is appropriated to each student; and six Argand gas lamps. Large and convenient cupboards are placed on one side of the room for the protection of the microscopes, instruments, and apparatus, when not in use; also large shelves for reagents and preparations; also a cabinet containing some hundreds of microscopical objects for the use of students. There is a plentiful supply of water, both hot and cold.

In fact, everything that could possibly be done to further the proper teaching of this most valuable subject has been done in a most praiseworthy way by the council of the London Hospital Medical College.

Resources of the Young Surgeon after Studentship.

THE PUBLIC SERVICES.

ARMY MEDICAL SERVICE.

THE appointment of assistant-surgeon in the Army is open to all who can prove their claim to it by superior answering. Candidates for the British Medical Service must be unmarried, and not more than twenty-eight years of age. The competitive examinations are held at Chelsea, usually in the first weeks of February and August. The candidate is not required to produce any other qualification before presenting himself for examination than his license to practise and certificates of registration, age, moral character, and physical capabilities.

Having received his diplomas in surgery and medicine, both of which are essential to his competition, the student is obliged to apply himself vigorously to the study of certain collateral subjects, which he does usually through the medium of a "grinder." He must perfect himself in chemistry, pathology, and comparative anatomy, and if he can throw a proficiency in botany and natural history and French and German into the scale, he will materially improve his position in the scale of merit, and establish for himself a character with the authorities for industry and scientific attainments.

The assistant-surgeon is subjected to three separate examinations within the first ten years of his service, each examination having a definite object—the first, to ascertain, previous to his admission into the service as a candidate, his scientific and professional education, and to test his acquirements in the various branches of professional knowledge; the second, after having passed through a course of special instruction in the Army Medical School, to test his knowledge of the special duties of an army Medical officer; and the third, previous to his promotion, to ascertain that he has kept pace with the progress of Medical Science.

The candidate having sent in his papers, and followed them to London, meets his competitors at Chelsea.

For the first two days of his examination he is employed in penning answers to printed questions; for the third and fourth days he is examined *visa voce* on all subjects; and on the fifth and sixth days he is tested by the diagnosis of disease at the bedside in the hospital, by the application of surgical apparatus, and by operations on the dead subject. This trial finished, the successful candidates (varying in number from fifteen to thirty) are selected.

SERVICE ON THE WEST COAST OF AFRICA.

A certain number of candidates, whose answering has been satisfactory, but not sufficiently so to entitle them to a place, were formerly offered appointments on the West Coast of

Africa, but recently they have been appointed to the Naval Medical Service, as vacancies on the Coast have not existed for some time. These situations, while they are subject to strong objection on the score of the deleterious nature of the climate, possess some advantages for those whose health can resist its influence. The districts comprised under the West Coast Districts are Sierra Leone, Gambia, and Cape Coast Castle. If the candidate accepts the appointment he is sent out at once, without the period of probation to which others are subjected at Netley Hospital. He is allowed to spend a year at home, on full pay, for every year spent in Africa, and the entire period at home and abroad should count as service for pension.

PROBATION AT NETLEY HOSPITAL.

The competitor who has been so fortunate as to obtain a place in the ordinary service is not allowed to join a regiment at once. He is obliged to undergo a probation of four months at Netley Hospital, near Southampton, where he is compelled to attend the following lectures—viz.: Hygiene, by Dr. Parkes; Pathology, by Dr. Aitken; Military Surgery, by Dr. Longmore; and Tropical Diseases, by Dr. Maclean. The lectures on Military Surgery include gunshot and other wounds; arrangements for the transport of wounded; duties of Army Surgeons in the field, during sieges, on transport, &c.; and other special subjects. Those on Military Medicine refer to the tropical and other diseases of the British possessions and colonies, and to the losses by disease. The lectures on Hygiene relate to the examination of water, air, food, clothing, &c., of the soldier; his duties and exercise, and the circumstances affecting his health, meteorology, statistics, and prevention of disease. The lectures on Pathology have reference chiefly to the scientific examination of tropical diseases, and of the other complaints which the Army Surgeon is especially called on to investigate. The candidates also attend the wards of the hospital under the Professors of Medicine and Surgery, to make themselves acquainted with the system of recruiting, and the modes of keeping the Army Medical Returns. They are also called on to make *post-mortem* examinations, to operate on the dead body, and pass through laboratory practice on the modes of recognising the qualities and adulterations of food, and on microscopic examination of morbid tissues and adulterations of food, &c. During his preliminary training here the student is understood to be in Her Majesty's service; he wears uniform, is under military discipline, and receives pay at the rate of five shillings per day, and two shillings per day for lodging money, if he be not provided with lodgings in the hospital. A sum of money equal to the half-yearly interest on £1,200, the surplus from the "Herbert Memorial," is at the end of each session awarded to the candidate who has the highest number of marks; the fortunate young man who wins this "Blue Ribbon of Netley" being tolerably certain to be well provided for. At the termination of the four months he is again examined in the subjects in which he has been instructed during that period, his marks are added to those obtained by him at the Competitive Examination, and his position on the list of merit determined by the total. Successful candidates are now eligible to be gazetted to a regiment, or employed on the staff, and enjoy all the rank and honour, pay and privileges, of Assistant-Surgeons, as provided by the regulations.

Thus it will be observed that the first, or Chelsea examination, simply admits the candidate to the service, and the conjoint result of it and the Netley examination determines his order of merit.

LIFE AT NETLEY.

The Medical candidates, as the surgeons are called until they have passed out of the Hospital by their second examination, are congregated at Netley, in addition to the commissioned officers who may be there. Each candidate

has to pay £5 towards the mess fund, one half on his arrival and the remainder when he has passed his second examination. He is then a member of the mess, and entitled to dine at any time during the remainder of his service. The cost of dinner is 2s. 4d. daily, not including wine, and of breakfast from tence upwards.

THE PROMOTION EXAMINATION.

But there is still one other which *must* be passed before he is promoted to full Surgeoncy, and *may* be passed at any time after five years' service.

A series of printed questions will be sent by the Director-General to the principal Medical officers of stations where Assistant-Surgeons may be serving, who will deliver these sealed questions to the Assistant-Surgeons, and see that they are answered without the assistance of books, notes, or communication with any other person. The answers are to be signed, and delivered sealed to the principal Medical officer, who is to send them, unopened, to the Director-General, together with a certificate from the Surgeon of the Regiment, or other superior Medical officer, that the Assistant-Surgeon has availed himself of every opportunity of practising surgical operations on the dead body.

The Assistant-Surgeon will also be required to transmit a Medico-Topographical account of the station where he may happen to be, or of some other station where he may have been resident, or else a Medico-Statistical Report of his regiment for twelve months.

If the Examining Board and the Director-General are satisfied with the certificates and answers, and with the report, the Assistant-Surgeon will be held qualified for promotion.

GENERAL OBSERVATIONS.

The bachelor Regimental Assistant-Surgeon, commencing with an income of £182 10s., in addition to quarters, coals, and candles, has the use of a soldier-servant for 10s. a month, and 15s. for washing. Mess bills and subscriptions vary according to circumstances, high in the cavalry, rifle brigade, and certain line regiments at home, but moderate in the artillery and line generally: about £10 would represent the outlay. Some can live cheaper by taking breakfast in their own room, the bed in one corner, the tub in another, not a wholesome arrangement. Respectable uniform, a gentlemanly appearance in dress must be maintained, and the servant clad for everyday work besides to wait at mess. Being on the staff as a rule is comparatively cheaper for married men, but the bachelor, friendless and homeless, will find there is nothing better than a good line regiment, especially where the colonel and the surgeon pull together and the latter takes a fair share of work. Those who marry early without means should remember they may reach the age of forty as assistant-surgeons with a large family to keep and drag about on an income under £300, deducting income-tax. The more pursuits and accomplishments a Medical officer has the better, specially if at the same time he is a good doctor and a gentleman. For the combatant officer a position is made; the Medical man makes his own as in civil life. The army would attract good men if the dead-lock and stagnation were removed by optional retirement at £1 a day after twenty years' service. Unless the Medical officer has private means he should not remain a day in England.

NAVAL MEDICAL SERVICE.

In applying to be admitted as an Assistant-Surgeon in the Royal Navy it is merely required to address a letter to the Secretary of the Admiralty, stating that you are in possession of a diploma from such a College—naming it; that you are desirous of being admitted as a candidate; when, if there are any vacancies, you will be informed when you

will be required to present yourself at Somerset House, London, for examination.

Having passed your examination you will, in the course of the following day, receive your appointment as acting Assistant-Surgeon to one of Her Majesty's ships, either for service on board that ship, or for service on shore, at one of the naval hospitals—Haslar or Plymouth. You will at the same time be informed that you are granted two or three weeks, as you may require, leave of absence, to enable you to provide your uniform and appointments. These you can get at any of the naval outfitters.

The expense of an Assistant-Surgeon's uniform is about £47 5s. You must also provide yourself with a set of surgical instruments, which will cost you from ten to fifteen guineas. All kinds of underclothing, towels, handkerchiefs, &c., may be purchased much more advantageously from a regular dealer in those things than from any naval outfitter.

ADVANCE OF PAY ON JOINING.

On joining your ship you will, if you wish it, be paid what is termed three months in advance, £30. Of course it is not all advance, as your pay will have been going on from the date of your appointment.

Every article of mess traps is now furnished by the Admiralty gratis. The same with your cabin furniture; every necessary article except bedding is supplied from the dock-yards. An officer on joining his ship has, therefore, nothing more to pay than his mess subscription monthly. This varies in ships according to the station they are on, from £2 10s. to £3 10s. per month. This subscription does not include anything for wine or liquors of any kind. Whatever amount of these you may consume will be paid for by you separately, at the end of each month or quarter. But as all wines are permitted, by sanction of the Admiralty, to be shipped free of duty, you drink them so much cheaper on board than you could the same qualities of wine on shore. The monthly subscription of say £3 with the Government allowance of £11 3s. 8d. per annum to each member in lieu of provisions, is generally found sufficient to meet all ordinary expenses of messing.

It is the custom in all wardroom messes to have an extra dinner on two days of the week—generally Monday and Thursday. The days so selected are styled "field-days." It is on these days that guests are invited to dine by the mess. The guests thus invited are called public guests, and such invitations entail no extra subscription from any one, except for the extra wine consumed. It is usual to invite the captain, and other superior officers that may be on board, once a week; the other public guests are so many of the junior officers of the ship; and, if in port, officers of the sister service, and other public functionaries. The captain, or admiral, if there be one on board, usually has two or three wardroom, and two or three gunroom, officers, to dine with him on every other day of the week than that on which he dines in the wardroom. Any member of the wardroom mess inviting a private friend to dine with him on board, pays usually from 2s. 6d. to 3s. 6d. (according to the rule of the mess) for his friend's dinner, in addition to any extra expense for wine.

The foregoing are the whole of the ordinary and extraordinary expenses of messing in the wardrooms of Her Majesty's ships, and which should not, with drinking a reasonable quantity of wine, beer, &c., exceed fifty guineas per annum.

Officers in the Navy, wherever they may be serving, can remit, by the paymaster of the ship, without any expense, any portion, or the whole, of their pay that may be due to them on the last day of each quarter.

SERVANTS.

Assistant-Surgeons are allowed only half a servant each ; or in other words, a servant between two of them.

These servants are entered on the ship's books with the rating of officer's servant. Their pay from the Admiralty is about £17 per annum and their provisions ; and where they are well conducted, attentive lads, it is usual for each of their masters to give them 10s. a month, which makes their pay up to about £29 per annum.

The pay of naval Medical officers has hitherto been the same as for their military brethren.

EXTRA PAY AND ALLOWANCES.

The following extra pay and allowances are paid to naval Medical officers under the conditions stated below :—

	At Home.	Abroad.
Inspectors-General in lieu of provisions for their servants, and of the ordinary allowances for provisions for themselves	£54	£130
Deputy Inspectors-Generals, Staff-Surgeons, and Surgeons, do. do.	£35	£112
Assistant-Surgeons do. do.	£30	£108

Staff-Surgeons, when serving in flag-ships on foreign stations, are allowed extra pay of five shillings per diem.

Staff-Surgeons, Surgeons, and Assistant-Surgeons, when serving in ships in which there is no accommodation for residing on board, as in drill ships for the Royal Naval Reserve, are allowed £50 per annum for lodgings, and one and sixpence per diem in addition in lieu of ship's rations.

Whenever Medical officers are employed on extra duty, they are allowed such extra pay as it may appear to the Lords Commissioners of the Admiralty the nature of the service merits.

Medical officers, when travelling on the public service, are allowed on the home stations—in addition to all expenses of first class fare by rail or otherwise—for subsistence :—

	Special Service occupying 12 hours.	Ditto for every 24 hours.
Inspectors-General and Deputy Inspectors-General	£0 13 0	£1 0 0
Staff-Surgeons and Surgeons	0 7 6	0 10 0
Assistant-Surgeons	0 6 0	0 7 6

PENSIONS OF MEDICAL OFFICERS.

Besides the half-pay awarded to Medical officers, there are three good-service pensions of 10s. each per diem awarded to the three inspectors-general who have completed the longest and most meritorious services.

There is also one Greenwich Hospital pension of £80 per annum awarded to a deputy inspector-general.

There are fourteen other Greenwich Hospital pensions of £50 each per annum, awarded to those fourteen deputy Inspectors-General, Staff-Surgeons, and Surgeons who are considered by the Admiralty to be most deserving of them.

PROMOTIONS.

An Assistant-Surgeon having served three years may be examined as to his qualifications for promotion to the rank of Surgeon. If he be serving abroad he may, if he wish it, be examined provisionally by an Inspector or Deputy Inspector-General and three Surgeons ; and as soon after his arrival in England as may be convenient for him to present himself at Somerset House for his regular and final examination. To enable Assistant-Surgeons to pass this examination satisfactorily they are granted, on application, two months' leave of absence to prepare themselves for it. The use of passing the provisional examination abroad is, that the Assistant-Surgeon, having served five years, is then eligible for promotion into any vacancy that may occur, as Acting Surgeon.

If the vacancy occurring shall have been caused by the death of an officer of superior rank, this promotion as

Acting-Surgeon will be confirmed as Surgeon on passing the regular examination at Somerset House. If the vacancy has occurred from any other cause than that of death, the Assistant-Surgeon appointed to fill it, whether he may have passed only provisionally or finally, will be appointed only as Acting-Surgeon until the pleasure of the Admiralty be known, who may either confirm him in it, or supersede him by the appointment of a Surgeon from half-pay.

Surgeons are promoted to the rank of Staff-Surgeons on twenty years' service, provided that ten years have been completed since passing for the rank of Surgeon.

By an Admiralty regulation, dated the 12th of July, 1867, promotion to Staff-Surgeon is to be open to officers for distinguished or special services, although they may not have completed twenty years' service.

An officer may be promoted to the rank of Inspector-General on the completion of thirteen years' service from the date of his entry into the Royal Navy.

PRIZE MONEY.

Medical officers share in the proceeds of all prizes captured from the enemy, of captures and seizures under the several Acts of Parliament passed relating to the revenues of customs, and of trade and navigation, for the abolition of the slave trade, for the capture and destruction of pirates and piratical vessels ; and of the rewards conferred for the same ; as also in the awards of all salvage granted to the crews of Her Majesty's ships and vessels of war, with other officers of corresponding ranks.

NOTE.—We do not advise Medical students to think of entering the Army or Navy, but the advantages of a certain income, the opportunity of study, the freedom from the drudgery of private practice, the pleasure of travel, must not be overlooked.

POOR-LAW MEDICAL SERVICE.

A YOUNG qualified practitioner, indisposed to be an assistant, and desirous of commencing general practice without investing any money in purchasing a succession, may, perhaps, obtain a Poor-law appointment, though he should scarcely expect to obtain a livelihood from this inadequately remunerated employment.

ENGLISH POOR-LAW MEDICAL SERVICE.

Prior to the passing of the Metropolitan Poor Act of 1867, the English Poor-law Medical Service may be said to have been in the hands of the Guardians, supervised by the Poor-law Board. Each parish in England and Wales had its guardians of the poor, and these parishes were grouped together to form unions. The unions were divided into districts for Medical relief. Union Medical officers, therefore, have the care of a district, or sometimes the care of the workhouse of the union—sometimes of both. The officer was elected by the guardians, and the appointment approved by the Board. He was required to have both a Medical and surgical qualification. In some instances these were specified, but almost always the London College of Surgeons and Apothecaries' Hall were the two most favoured diplomas. For this reason London students will still continue to take these qualifications, whatever else they may add to them. But the L.R.C.P. Lond. is now recognised as a full qualification, both Medical and surgical. The salaries of Poor-law appointments are very low. They are, however, sought after by young men as a means of getting into practice, and are often almost obligatory in the country to prevent fresh opposition being introduced. The Metropolitan Poor-law Act, 1867, assimilates the Poor-law, so far as London is concerned, to that of Ireland, and the Poor-law Board is now merged in the new Local Government Board. It has established in London asylums and dispensaries, and distributed the cost of supporting them over the metropolis.

THE IRISH POOR-LAW SERVICE.

THE newly-qualified Medical Practitioner, who may elect to try his luck in the Irish provinces, sets his hopes, in the great majority of instances, upon obtaining one or more Poor-law Medical appointments in some district where there is hope of private practice. There are 163 workhouses and 798 Dispensary Medical Officers besides apothecaries. The number of vacancies that occur annually averages 100. The average salary in this service is £90; and when it is taken into consideration that, in the vast majority of rural districts, it is necessary to keep a horse, and in some a boat as well, the average area being from forty to sixty square miles, it is plain that there will not be a very large margin left from the public emoluments. The Medical Officer will also have the refusal of the Registrarship of Births, Marriages, and Deaths, which office in country districts seldom yields more than £10 a year, and often not half that amount. Despite the miserable salary, and the very many discomforts of dispensary life, these appointments are generally eagerly sought for—firstly, because they afford the new comer a certain though hardly-earned salary to supplement his private earnings; and, secondly, because, if not secured by the new comer, they would of necessity bring a competitor for practice into the field, and inasmuch as private income is of far greater import than public earnings, country Medical practitioners are obliged to undertake the public duty in order to save to themselves the monopoly of their private emoluments.

APPOINTMENT.

The qualifications required by the Poor-law Commissioners are a licence in Surgery or a diploma in Medicine, and a diploma in Midwifery; the candidate must also be twenty-three years of age.

The appointment lies with the Dispensary Committee, who elect by vote. As politics and religious feeling run high in Ireland, these elements enter into the election of Poor-law Medical Officers. Family interest also possesses great weight.

The candidate will do well to bear these facts in mind, as his personal attendance on the day of election will be required. And whatever other qualification he may have, he will then find that his compatibility in these respects with the majority of the committee is essential. And, accordingly, he had better first make himself acquainted with the local peculiarity, whatever it may be, before he enters on his candidature, otherwise, in all probability, any expenditure that he may make in the matter will be simply thrown away. We may here observe, also, that in very many instances the appointment is virtually made before the advertisement appears for a Medical Officer, in which case also candidates are put to unnecessary trouble and expense under false pretences.

CONTROL.

Each district is under the direct control of a committee composed of the neighbouring landholders, the appointment of Medical and other officers are made by this committee, and the entire management of the district is under their control. Their acts are, however, subject to the approval of the Poor-law Commissioners, who have the power either of interposing their veto on any appointment, or even of expelling an officer by a "sealed order," without trial or accusation, and without the resource of appeal or investigation. This salary is paid by the Board of Guardians, and no increase or decrease can be made in the amount without their assent and that of the Commissioners. Under the late Sanitary Act the committee may recompense the Medical Officer for special services, such as those during an epidemic of cholera, or for sanitary reports. The number of unions in Ireland is 163, to each of which is attached a Medical Officer, who is appointed and controlled by the Board of Guardians in the same manner as the Dispensary Surgeon is by his committee. The salary is usually better

than that of the Dispensary Doctor, and the duties of a more easy and satisfactory description, inasmuch as the duty is confined to daily attendance at the Workhouse Hospital, and no night visits out of doors or any long journeys across the country are involved.

DUTIES.

The duty of the Dispensary Doctor is two-fold. He is to attend his Dispensary on a given day or days in the week. Frequently there are two dispensaries in the district, separated from each other by several miles, and he will have, perhaps, to attend two days a week. He has also to visit at any hour of the day or night a sick person, for whose relief a visiting ticket has been issued by a member of the committee or by the relieving officer, and to continue his attendance as often as may be necessary until a termination of the case. Moreover, he has a great many registry books to keep, and a multitude of returns to make, and in the majority of districts he has to make up all the medicines for the poor.

The pressure of these duties is in the greatest degree dependent on the goodwill of the members of his committee. If the Medical man be a favourite with his masters they will give him very little trouble with "scarlet runners," as the visiting tickets are, from the colour of the paper on which they are printed, humorously called, and will be unwilling to trouble him even with cases deserving of personal attendance.

If, on the other hand, it is his misfortune to come in contact with some of the half-bred committee-men, who know nothing of the treatment fit for an educated gentleman, or cherish a personal spite, the discharge of his duties may become simply unbearable. He may be peremptorily summoned, in any weather, at any hour, and to any distance, to a case which he may probably find to be altogether trivial, or to a person whom he may know to be perfectly well able to pay—Aye! even the committeeman's own brother or daughter.

By a recent Act of Parliament Poor-law Medical Officers may now receive a pension of *one-sixtieth of their salary for each year of service* on being incapacitated from illness or old age. This grant is strictly at the discretion of the guardians, nevertheless it has been given in most cases in which physical incapacity has been clearly proved. It is, however, at best a miserable resource, and can by no means be calculated upon as a provision for old age.

Assistancies in English General Medical Practice.

THE most usual portal of entry into general practice in England is by an assistancy to some practitioner already well-established in business; and, moreover, to the advanced student the position of unqualified assistant is, frequently, in itself the means of livelihood and professional advancement until he finds himself able to qualify for succession to the practice by taking his diplomas. As may be presumed, the duties of the office are very various, and the relations between principal and assistant very complex, so much so as to demand a special volume for themselves. Mr. Langley has supplied this want by his volume "Via Medica," from which we are permitted to extract such excerpts as we are able to find space for.

SURGEONCIES IN THE MERCANTILE MARINE SERVICE.

THE appointment of surgeon in sea-going vessels is much sought after by young surgeons who are desirous of seeing a

little more of the world than school, college, or home have shown them; but the office is seldom held for more than a few years, or regarded as a permanent provision for life. These appointments are almost uniformly in the gift of directors and secretaries of companies, and of the owners themselves, with whom, as may be believed, personal influences are a better recommendation than any professional qualification.

The Peninsular and Oriental Service heads the list in respect of its eligibility, and admission to it is a matter generally quite outside the range of the unfriended candidate.

The appointment is made by the directors, and the surgeon is bound for three years' service. He is placed always at first on some of the lines at the other side of the Isthmus of Suez, and is drafted into the "home" service between England and Alexandria, as vacancies occur. The pay is at first twelve guineas per month, which is afterwards increased, and he is permitted to receive such fees as may be offered for attendance on passengers, whom, however, he is bound to attend without charge, if required to do so. Occasionally large fees are paid by grateful patients; but usually the income from this source is not large, and less in the home service than elsewhere.

The surgeon can resign on giving a month's notice when on leave—*i. e.*, when his ship is laid up.

The Cunard and other American mail lines select their surgeons through the interest of owners and managers. The American ships are bound to carry American surgeons, and the English ships English Medical officers. The pay varies from ten guineas per month upwards, and the arrangement may be terminated by the surgeon at any time that the ship is laid up. If, however, he has signed special articles, he will of course, be bound by them.

The West India Mail Service admits candidates only between the ages of twenty-two and forty. A regular curriculum similar to that required by the licensing bodies, is necessary, and a special examination in climatic disease is administered to the candidate.

The following is the scale of pay:—At entrance £100 a-year, Senior Surgeon, £120, amounting with all fees generally to about £200. When the ships are engaged on transport service the pay is doubled. Surgeons in the service have a private cabin and a boy to assist in dispensing. They mess in the saloon, and are found in every requirement free of charge. A pint of wine is included in each day's rations, or in lieu of it a payment of 1s. 3d. At entry surgeons are requested to join vessels in the West Indies or Brazils, relieving surgeons longest out, and being themselves relieved in turn.

The emigration Commissioners are now reducing their staff, and making no appointments to vacancies as they occur. Many of the trading ships which carry emigrants to New Zealand and Australia take surgeons only on their outward voyage, and call at China for silks and other freight on their way home. Surgeons to these vessels are paid only £35, and finding it impossible to obtain a passage home again are compelled to settle in the colonies, which are accordingly overstocked.

European Communities.—There is a growing demand for surgeons for small European colonies, and several desirable appointments have thus been recently made. A number of colonists feeling the want of efficient Medical advice subscribe an annual guarantee salary of say £600. These appointments have been made through the agency of Dr. Langley, of Lincoln's Inn Fields; as, however, they are few and somewhat lucrative, the communities are entitled to expect a high degree of education and intelligence in their Medical attendant.

The Students' Life, Education, and Qualifications.

THE GENERAL MEDICAL COUNCIL.

To THIS body is entrusted the supervision of Medical education, and it has made a number of recommendations, the majority of which have been accepted by all the Examining Bodies, and are, consequently, found in their regulations. The student has, therefore, nothing to do with the Council, except that he must take care to be duly registered as a student of medicine, at the commencement of his career, at the office, Soho Square.

MEDICAL REGISTRATION.

All duly qualified Physicians, Surgeons, Medical Graduates, and Apothecaries, are required by the Medical Act 21 and 22 Vic, c. 90, to be registered before they can hold any public Medical or surgical appointment, or issue valid Medical certificates.

The Medical Registration of any Practitioner may be effected, on application, in writing (according to a form to be had at either of the Branch Offices or at Soho Square), and producing, or transmitting with such requisition the *Diplomas* to be registered, and also paying or remitting the fee which is regulated by the Medical Council, viz., £5 for first registration, and 5s. for every qualification which may be subsequently added.

MEDICAL STUDENTS are required by the Medical Council to be registered, but they must previously have passed a preliminary *Arts Examination*. In order to effect this each student should apply according to a form accompanied by a certificate of his having passed such examination, same to be lodged with the Registrar, who will thereupon enter the name in the Students' Register, and issue a certificate to that effect. No fee is required from *Medical Students* for their registration.

THE CAREER OF THE ENGLISH MEDICAL STUDENT.

THE young gentleman who is about to enter the Medical Profession in *England* has more than one course open to him, whether he decide on fulfilling his curriculum in London or in one of the provincial schools. The latter course is generally determined by local causes with which pupil and parent are both familiar. We propose, therefore, in this place, to point out a few things that concern alike the London or provincial Medical student.

APPRENTICESHIP.

First of all, as to apprenticeship. The only English corporation that absolutely requires an apprenticeship is the Society of Apothecaries, which is bound by Act of Parliament. The clause, however, is very liberally interpreted, and the apprentice may, during his term, fulfil part or the whole of the curriculum. *The master must possess the licence of the Company*, but he may practise any department of the Profession. There is much difference of opinion as to the value of an apprenticeship. Some profess to despise it, and regard it as a badge of trade. There are, however, many advantages in the system, if carried out in the liberal mode we have spoken of; and we feel sure neither pupil nor parent would ever regret having entered into such an agreement with a

Medical gentleman of position and honour. Thus, suppose a pupil to be bound apprentice to a Licentiate of the Apothecaries' Company for a period of five years, with the right to attend lectures and hospital practice during the last three years, he enjoys the following advantages: In the early part of his pupilage he not only learns practical pharmacy, and becomes acquainted with the more generally used articles of the *Materia Medica*, but may be assisted in preparing for the Preliminary Examination. Moreover, he prepares himself to take, should he ever wish to do so, the post of assistant to a general practitioner, as the experience he has thus acquired will procure him a situation in preference to prizes, gold medals, and even university distinctions. Again, this experience is of the very highest value, should he decide on settling in general practice after he is qualified. On the whole, then, this modified apprenticeship system is equal to any, and parents who know a practitioner to whom they would willingly entrust their sons, cannot do better than pay him a fair premium. Those residing near will occasionally be able to arrange for an out-door apprenticeship.

PUPILSHIP.

Supposing, on the other hand, that the plan of apprenticeship be rejected, a young man may still become the pupil of some one in practice. This is often done by those who aim at the higher branches of practice. A physician or surgeon who will give some time to the superintendence and direction of a pupil's study certainly offers him great advantages, and those who can afford thus to act will not regret the expense of providing their sons with such a guide.

HOSPITAL STUDY.

Lastly, a pupil may enter at any of the London hospitals without any such preparation. He has only, *provided he has passed a preliminary examination*, to pay the first year's fee, and he is admitted at once to all the dignity of a Medical student. A preliminary examination recognised by the General Medical Council *must* be passed before entering a hospital. He should decide on the diplomas he requires, and guide his studies accordingly. Most of the schools now have a composition fee, entitling to all lectures and practice required for the ordinary qualifications in medicine and surgery. They also mostly have another sum, very little higher, entitling the student to perpetual attendance on all lectures and hospital practice. It is better to take out the perpetual ticket, as all contingencies are thereby provided for. The fees are mostly payable in two or three instalments, at the commencement of each Winter Session. The Dean will always forward details, as well as any special information of which a student may find himself in need. The first instalment varies from forty to fifty guineas; the second is a like sum; the third usually only makes the whole sum paid a hundred guineas or a little over. There is a tendency to slightly increase the expenses in consequence of the great improvements in the schools, and the additional requirements of the Examining Boards, and no doubt the fees in London will gradually rise.

RESIDENCE.

The student who comes from the country to enter in London not unfrequently requires lodgings. Those who can live with relatives and friends are, of course, best suited; but not a few find themselves very comfortable in furnished apartments, which are to be had in respect-

able streets near all the hospitals. Two brothers or two friends can, of course, do this a little less expensively than one. The price varies with the season a little, and some can afford more than others, and therefore can always have a selection of better rooms.

It should be mentioned that one or two of the Medical schools have collegiate institutions in connection with them, where rooms may be had instead of the more usual plan of taking lodgings. At many schools some of the lecturers receive pupils, and all of them will at any time afford special information to those who may inquire of them.

Residence settled, student life begins by hearing the Introductory Lecture, at the conclusion of which the fees may be paid, unless they have already been handed over.

PRIZES.

As to contending for prizes, there are differences of opinion. Diligent attendance on the classes and in the wards will enable the student to store his mind with knowledge fitting him for his profession, and this should be his first aim. Gold and silver medals are honourable distinctions, but only secondary ones. We never competed for them, nor encouraged others; and some of the most eminent men hold the same views. Others, however, differ from us, and the pupil may judge for himself. Competition for appointments to dresserships and other offices, where much practice is seen, stands on a different footing. No prizes can equal such posts; and the possibility of getting them should influence largely the choice of a school. In some schools they must be paid for. In others, the diligent gain them without extra expense. The student, having selected his hospital and school, has chosen his teachers. We have only to remind him that however able they may be, the result depends on his own application.

CURRICULA AND QUALIFICATIONS.

The information most important to students may be divided into two parts:—

I.—The regulations with which they must comply before they can present themselves for examination to any of the Licensing Bodies.

II.—The means that exist to enable them to do so.

In the first division are to be placed the regulations of the Corporations; in the second, some account of the many Schools of Medicine and Hospitals where professional education can be pursued. A natural supplement to this information is a brief sketch of the career open to young men after they have obtained their diplomas, especially in the Public Services.

According to this plan, we proceed to consider, first of all the regulations of the Qualifying Bodies. These may also be divided into two classes—1. The Universities; 2. The Corporations.

Oxford and Cambridge.—The elder English Universities have of late years opened their doors much wider than heretofore, and that without losing any of the prestige they possessed. Those who propose to follow their course of education need not any longer enter at any particular College or Hall, although it will probably be long before lodger students will be very numerous. There are advantages in the College life that will not be willingly given up by those who can afford it, and, for a purely Medical career it would be perhaps preferable for those who would not like to enter a College to graduate at the London University.

University of London.—The Medical degrees of this University have now obtained a reputation second to none, and no student can therefore propose to himself a higher qualification. The training is rather longer than that required for the diplomas of most of the corporations. The examinations are very stringent, and it is in after years that the student will feel the gratification of having obtained such a degree. Every student is required to go through the full course of hospital studies *after* he has passed the matriculation examination. It is, therefore, very desirable he should matriculate before entering a Medical school, otherwise two years will be lost. The matriculation examination of this University is accepted as a preliminary by the Medical Council, and therefore the labour bestowed in preparation will serve the student's purpose even if he do not proceed to a degree. The Medical degrees of the University are Bachelor and Doctor of Medicine, and Bachelor and Master in Surgery. Degrees of Bachelor and Doctor of Science are also now obtainable. There are at each stage of the graduate's career, examinations for honours, which afford the student the opportunity of gaining highly-prized distinctions in various branches. There are also scholarships for the most successful.

University of Durham.—The degrees of Bachelor and Doctor of Medicine are granted by this University, as is also the degree of Master of Surgery. There is also a licence in medicine, to obtain which residence is not essential. A licentiate cannot pass to the M.B. until he has obtained the degree of B.A., or passed an equivalent examination. Only M.B.'s of twenty-one terms' standing can proceed to M.D.

There is a Medical scholarship of £25 tenable for four years, and the fees, both Collegiate and University, are very moderate.

From the Universities we pass to the other bodies that are empowered to give authority to practise,

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

The Fellowship of this College is only attainable by election. No one can be proposed who is not a member of four years' standing.

THE MEMBERSHIP.—A person may become a Member of this College without holding a degree in Medicine, or indeed any other diploma. This is not very often done; for the Membership gives no right to the use of the title doctor, though some Members not possessed of a degree do so style themselves. This is, however, in direct violation of the rules of the College to which a member pledges himself on admission. The curriculum extends over four years.

Graduates in Medicine of any British University are admitted to an examination for the membership. Such graduates are exempt from some parts of the examination—*e.g.*, anatomy and physiology. Even foreign graduates of accredited Universities have no difficulty in being admitted to examination.

THE LICENCE.—This diploma authorises the holder to practise his Profession as a Licentiate of the College. Unless a graduate of some University, he is forbidden to use the title of doctor, but we regret to say many do so. At first it was regarded as a Medical diploma for the general practitioner, intended to supersede that of the Apothecaries' Company. The examination is conducted by specially appointed examiners, and is complete in the several departments.

Not quite five years ago we had to record the most important change that has ever occurred in reference to the qualifications of general practitioners. This licence of the London College of Physicians was then recognised by the Poor-Law Board as a qualification in surgery as well as medicine. Consequently, this single diploma is sufficient to enable any one to take a Poor-law appointment. Any one contented with the diploma of L.R.C.P. Lond., would thus have all he needed as a legal qualification.

It is to be supposed that the College will follow up its advantage, and protect all its Licentiates in the exercise of all branches of the Art of Healing.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

No Corporation has exercised so great an influence over the Profession in England as this. Without the M.R.C.S. it is not easy to obtain any English surgical appointment. In a parish appointment, its membership, though no longer essential, carries great weight. Hence, most English students intend to prepare themselves for this, which, together with a Medical qualification, suffices for every purpose of the general practitioner. The College has two grades, Member and Fellow. It also gives a diploma in Midwifery, but this is mostly confined to those who are already Members.

THE FELLOWSHIP.—Members of long standing can be admitted by election. As, however, this grade is also obtainable by examination, this is the more usual mode. Consulting surgeons mostly take the Fellowship by examination, though there are many hospital surgeons in London who have contented themselves with remaining Members.

A Member of the College of eight years' standing is admitted to examination on the production of a certificate of three Fellows, that he has been engaged for eight years in the practice of surgery, and is a fit and proper person to be admitted a Fellow.

THE MEMBERSHIP.—This diploma gives no vote in the affairs of the College. It is in effect only a licence to practise, and corresponds with the licentiateship of the Edinburgh and Dublin Colleges.

In future, candidates for the diploma will be examined in the practice of medicine, and also in the practical employment of splints, bandages, and other surgical appliances.

APOTHECARIES' SOCIETY OF LONDON.

The Licence of the Worshipful Society of Apothecaries is perhaps the most useful Medical diploma for the general practitioner in England. The monopoly enjoyed by this body for many years, in this respect, is not easily to be disturbed. The laws of many institutions require their Medical officers to hold this diploma, and these laws are not readily altered. Though other Medical qualifications are recognised by the Poor-law Board, there is no doubt that the guardians throughout the country—and they elect the Medical officers—are familiar with the diploma of the Apothecaries' Society, and it is to them more of a guarantee than other qualifications, of the value of which they are ignorant. The drawback to many a student is that, constrained by the Act of Parliament, the Society requires apprenticeship. This clause has, however, received a very liberal interpretation, and every pupil of a licentiate, who is certified to have served *after the manner* of an apprentice, is considered to have fulfilled the requirement. During this term he may also have carried on his hospital studies. Everyone, therefore, who can show this certificate, intending to settle in *England* as a general practitioner—even if he take other diplomas—would probably consult his own interest by becoming a Licentiate of the Apothecaries' Society; and as the fee is only six guineas, a very large number of young men will, we doubt not, secure this possible avenue to appointments.

HOSPITALS AND SCHOOLS OF MEDICINE IN LONDON.

In entering a School of Medicine, application is to be made to the Dean. In London the fees range from 80 to 100 guineas for the course of study required for the ordinary diplomas. The sum, if paid at once, is less than if paid in two or three instalments. From 40 to 50 guineas at the commencement of each of the two first years is an ordinary arrangement, the remainder being paid on entering the third winter. The amount of the

fees does not differ so much as to make it of importance in the selection of a school.

THE LONDON HOSPITAL AND COLLEGE.

The Medical College of the London Hospital has been greatly enlarged, and is now very complete, lectures and demonstrations being given in all the subjects required by the Medical examining boards. In the new buildings, a reading room and other accommodation has been provided for the students, the museum has been more than doubled in size, and a physiological and histological laboratory has been erected and amply furnished with microscopes and all the needful appliances for practical instruction and original research. Pathology is also systematically and practically taught in this school. The College, therefore, worthily supplements the great East End Hospital, which has long been famed as one of the finest fields for practical study. There are now a large number of scholarships and prizes of considerable value, but more important still to studious men, all the numerous appointments in the wards are open to pupils without extra payment, and it is almost impossible to exaggerate the value of the dresserships, clerkships, house surgeoncies, house physiciancies, and other residential positions in a hospital of the first magnitude, where the staff take great interest in the development of its educational resources.

Pathology is here taught in a systematic manner, and there is a well-fitted histological and physiological laboratory complete in all its arrangements.

ST. BARTHOLOMEW'S HOSPITAL.

The great city hospital has always attracted large numbers of students from all parts of the country, so that the school is very flourishing.

H.R.H. the Prince of Wales is the president of the hospital, which receives within its walls upwards of 5,000 in-patients annually, and its out-patients and casualties amount to more than 100,000 annually. It contains 650 beds, of which 403 are allotted to surgical, including ophthalmic, orthopaedic, aural, and syphilitic cases, and 247 to Medical cases and diseases of women and children. One of the assistant-physicians sees the Medical out-patients daily, between eleven and two; and one of the assistant-surgeons sees the surgical patients daily, between twelve and two.

Accommodation is provided for residence of students in the college connected with the institution, for which an entrance fee of 2*l.* 2*s.*, and a further payment of caution money, 3*l.* 3*s.*, is required. The cost of maintenance varies from 30*s.* to 38*s.* per week, payable in each term; and the term of residence is unlimited.

GUY'S HOSPITAL.

This old favourite borough school still attracts as many students as ever. The school has long been one of the most popular in the metropolis, and still keeps up its old renown. In special departments, Guy's is the most advanced. This hospital set the example of giving the appointments to its special departments to gentlemen not on the general staff.

Guy's is situated close to the London Bridge Railways. Hence great facilities for getting to any part of London or the country. It is quite practicable for students to reside a little distance down either of the lines that converge at this point, and thus enjoy the benefit of country air during their hospital career. For those who wish to live close to the hospital, there are many lodgings to be had at a moderate price.

ST. THOMAS'S HOSPITAL.

The opening of the new buildings on the Thames Embankment, and the strengthening of the professional staff, has given a new impetus to this school.

There is accommodation for residence and [free maintenance in the college-house for the two house-surgeons, resident accoucheurs, one dresser, one obstetric clerk, and assistant obstetric clerk, which appointments are awarded by competition. There are many prizes and scholarships.

UNIVERSITY COLLEGE AND HOSPITAL.

This is situated in a very central position, near the Gower Street station of the Underground Railway, affording facilities for gentlemen residing in many parts of London. The college gives instruction in every department of science, and specially prepares students for degrees in all the faculties at the University of London. There is, however, no theological faculty, the College, like the University with which it is in intimate connection, being founded on the non-sectarian principle. The

Medical faculty and the hospital are very complete, and flourishing as educational institutions. There is also a Faculty of Science. The University College School specially prepares boys to be ready at a proper age to enter the College.

KING'S COLLEGE.

This College gives instruction in all the faculties, and has a theological department. It was established by Church of England persons, in opposition to University College, which is a non-sectarian institution. King's, then, is the Church of England College. The College is situated close to Somerset House, having a frontage on the new Thames Embankment, within a few minutes' walk of a station on the Underground Railway. There is also a junior school in connection with this College, to prepare boys to enter the College at a proper age. The hospital is only a short distance from the College, and although small, the renown of its staff has always kept up its reputation, so that King's is one of the most popular of the Medical educational institutions in London.

CHARING CROSS HOSPITAL.

This hospital, though one of the smaller ones, derives from its situation great advantages. It is one of the most central positions in London, where there is constant communication with every part. In connection with it the practice of the Royal Western Ophthalmic Hospital close by, affords an excellent opportunity for the study of that branch of the Profession. Other special departments have been established, and the authorities seem to have the courage to establish them on a liberal basis, the hospital staff not monopolising these appointments.

ST. GEORGE'S HOSPITAL.

The chief advantage of this school, is its unrivalled position, at the corner of Hyde Park—perhaps the most salubrious part of the metropolis. Students can easily find lodgings within half an hour's pleasant walk. It is, perhaps, the most aristocratic of the London schools, and the present staff maintain their position as worthy successors of Hunter, Brodie, and other worthies who formerly taught in it.

MIDDLESEX HOSPITAL.

There is a special department for cancer cases affording accommodation for thirty-three in-patients, whose period of residence in the hospital is unlimited. Wards are also appropriated for the reception of cases of uterine disease and of syphilis, and beds are set apart for patients suffering from diseases of the eye.

Special attention is bestowed on the clinical instruction of the students both in the wards and out-patients' rooms. Three clinical prizes, including the governors' prize of twenty guineas, are annually awarded to those students who pass the most satisfactory examination at the bedside, and in the *post-mortem* room. Class prizes are also given, and six resident clinical appointments are annually awarded after competitive examination, to students who have completed their education and complied with the regulations of the school. The officers thus appointed reside and board in the hospital free of expense.

The college tutor assists all general students free of charge, especially those who are preparing for examination, and his daily instruction is arranged with a view to avoid the necessity of students obtaining any private teaching apart from that of the Medical school.

WESTMINSTER HOSPITAL.

This is near the Abbey and the Houses of Parliament, and will be found convenient for all in that neighbourhood. It is well appointed in every respect, and one of the most moderate in respect to fees. The whole course of study for the usual examinations may here be completed for seventy-five guineas, payable in instalments. The perpetual fee is only eighty guineas. Resident appointments, clerkships, and dresserships, are all conferred without extra payments. Suitable lodgings may be obtained in the neighbourhood, and at not more than a quarter of an hour's walk from the hospital.

ST. MARY'S HOSPITAL.

There is a Medical School in connection with this hospital, which is located at Paddington, in close proximity to the Great Western terminus. Students with slender purses will find the neighbourhood of the hospital a very moderate one as regards lodgings, and easy of access by omnibus and the Underground Railway to all parts of London. Three resident Medical officers are appointed for twelve months, and an

obstetric officer for six months, who board free of expense in the hospital. A resident registrar is also appointed from amongst the students, with a salary of 100*l.* a-year. These appointments are awarded after competition, without additional fee. There are several scholarships.

OTHER METROPOLITAN HOSPITALS AND INSTITUTIONS.

ROYAL SCHOOL OF MINES [GOVERNMENTAL].—During the twenty-second session (1872-73), which will commence on the 1st of October, courses of lectures and practical demonstrations will be given by the Professors. The fee for students desirous of becoming Associates is £30 in one sum on entrance, or two annual payments of £20, exclusive of the Laboratories. Pupils are received in the Chemical Laboratory, under the direction of Dr. Frankland, and in the Metallurgical Laboratory, under the direction of Dr. Percy. These Laboratories will be re-opened on the 1st of October. By order of the Lords of the Committee of Council on Education, the instruction in chemistry, physics, and natural history will be given in the new buildings, in the Exhibition Road, South Kensington.

ROYAL FREE HOSPITAL, Gray's-inn Road.—102 beds. Physicians: Dr. Hassall, Dr. O'Connor, Dr. Cockle, Dr. Rickards. Surgeons: Mr. Thomas H. Wakley, Mr. Victor de Méric, Mr. Alexander Marsden, Mr. Frederick Gant, F.R.C.S., Mr. John D. Hill, F.R.C.S. Dentist: Mr. Hasler Harris.

GREAT NORTHERN HOSPITAL, Caledonian Road, N.—Physicians: Dr. Leard, Dr. Hardinge, Dr. Cholmeley, Dr. F. C. Webb, Dr. Jephson, Dr. Cruicknell. Surgeons: Mr. Gay, Mr. W. Adams, Mr. T. Carr Jackson, Mr. Spencer Watson, Mr. Osman Vincent, Mr. J. A. Bloxam. Obstetric Physician: Dr. Murray. Diseases of the Eye: Mj. B. J. Vernon. Aural G. C. P. Surgeon: Mr. Harvey.

WEST LONDON HOSPITAL, Hammersmith, W.—68 beds. Consulting Physicians: Drs. H. Bence Jones and W. O. Priestley. Consulting Surgeons: Messrs. S. A. Lane, F.R.C.S., and W. Bird, F.R.C.S. Physicians: Drs. Goddard Rogers, H. Maudsley, and A. Wiltshire. Surgeons: Messrs. W. F. Teevan, F.R.C.S., and Alfred Cooper, F.R.C.S. Junior Physicians: Drs. Thorowgood and F. Simms. Junior Surgeons: Messrs. J. A. Bloxam and H. T. Butlin. Secretary and Superintendent: Mr. T. Alexander.

NORTH LONDON HOSPITAL FOR CONSUMPTION, London and Hampstead.—52 beds. Consulting Physicians: Drs. Routh and Fuller. Consulting Surgeons: Sir W. Fergusson, Bart., and Mr. H. Smith. Physicians: Drs. Timms, Johnson, Dudley, Drysdale, Prosser James, Gosset Brown, and Lomas.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Physicians: Dr. R. P. Cotton, Dr. R. Quain, Dr. J. E. Pollock, Dr. E. S. Thompson, Dr. C. T. Williams. Assistant-Physicians: Dr. R. D. Powell, Dr. J. Tatham, Dr. R. Thompson, Dr. Burney Yeo, Dr. F. Roberts.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park. Office: 24 Finsbury Circus, E.C.—Physicians: Drs. Peacock, J. Risdon Bennett, Birkett, Ward, and Andrew. Consulting Surgeon: Mr. J. Hilton. Assistant-Physicians: Drs. Thorowgood, Sutton, Shepherd, Baumler, Smith, and Corfield.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road, E.C.—Established 1814. 12 beds. Consulting Physicians: Drs. C. J. Fox and Herbert Davis. Physicians: Drs. Horace Dobell, H. H. Cruicknell, G. Goddard Rogers, A. E. Sansom, and P. J. Hensley. Consulting-Surgeon: Mr. J. Adams. Surgeon: Mr. Alfred Cooper.

HOSPITAL FOR DISEASES OF THE THROAT, Golden Square, W.—Consulting Physicians: Dr. Billing and Sir W. Jenner, Bart., M.D. Consulting Surgeon: Sir W. Fergusson, Bart. Physicians: Drs. Morell Mackenzie, Semple, and Prosser James.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, 23 and 24 Queen Square, Bloomsbury.—Physicians: Drs. Ramskill, Radcliffe, Hughlings Jackson, and Buzzard. Assistant-Physicians: Drs. H. Charlton Bastian, Elam, and Maclure. Medical Superintendent: Dr. Herbert Tibbits.

ROYAL ORTHOPÆDIC HOSPITAL, 315 Oxford Street.—Surgeons: Messrs. B. E. Brodhurst and J. D. Hill. Secretary: Mr. Maskell. Operations on Thursdays at 2 p.m. The hospital is open to all legally qualified practitioners.

ROYAL LONDON OPHTHALMIC HOSPITAL, Bloomfield Street, Moorfields, E.C.—Founded 1804. 100 beds. Consulting Physician: Dr. F. J. Farris. Consulting Surgeon: Mr. J. Dixon. Surgeons: Messrs. Critchett, Bowman, Wordsworth, Streetfield, J. W. Hulke, G. Lawson, and J. Hutchinson. Assistant-Surgeons: Messrs. J. Couper and J. Soelberg Wells, M.D. House-Surgeon: Mr. F. Ewbank.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, Charing Cross.—Fee for attendance on the practice and lectures: Three months,

£3 3*s.*; perpetual, £55*s.* The office of house-surgeon is open for competition to students attending the hospital. Operations daily at 2 p.m.

LONDON SCHOOL OF DENTAL SURGERY, 32 Soho Square.—Lectures are delivered in winter on Mechanical Dentistry, by Mr. James S. Turner, M.R.C.S., L.D.S., on Wednesdays, at 7 p.m.; on Metallurgy in its application to Dental Purposes, by Mr. G. M. Makins, M.R.C.S., on Fridays, at 6.30 p.m. In summer, Mr. S. H. Cartwright, M.R.C.S., L.D.S., lectures on Dental Surgery and Pathology; and Mr. C. S. Tomes, M.R.C.S., L.D.S., on Dental Anatomy and Physiology (Human and Comparative). General fee for special lectures required for the curriculum, £15 15*s.*

DENTAL HOSPITAL OF LONDON (in connection with the above).—Surgeons: Messrs. Fox, Underwood, Gregson, Coleman, Harding, and Hill. Assistant-Surgeons: Messrs. Moon, Medwin, Tomes, Lane, Bartlett, and S. H. Cartwright. Dental House-Surgeon: Mr. R. Hepburn, jun. Fee for two years' hospital practice required by the curriculum, £15 15*s.*

HOSPITAL FOR DISEASES OF THE SKIN, 55 Great Marlborough Street, W.—Surgeon: A. J. Balmanno Squire, M.B.

HOSPITAL FOR DISEASES OF THE SKIN, 25 New Bridge Street, E.C.

NATIONAL INSTITUTION FOR DISEASES OF THE SKIN, Gray's-inn Road.

ST. JOHN'S HOSPITAL FOR SKIN DISEASES, 45 Leicester Square, W.C.—Surgeon: J. L. Milton, M.R.C.S. Physician: Dr. R. Locke Johnson.

LOCK HOSPITAL AND ASYLUM: FEMALE, Westbourne Grove, Paddington. MALE, 91 Dean Street, Soho, W.

SEAMEN'S HOSPITAL (late *Dreadnought*), Greenwich, S.E.—Physicians: Drs. Stephen H. Ward and Reginald Thompson. Senior Medical Officer: Mr. Harry Leach. Surgeon: Mr. W. Johnson Smith. House-Physician, Dr. Lyell. House-Surgeon: Dr. O'Farrell.

HOSPITAL FOR WOMEN, Soho Square.—Established 1842. 68 beds. Physicians: Dr. Protheroe Smith, Dr. Alfred Meadows, Dr. Heywood Smith. Surgeons: Mr. John Scott, Mr. Christopher Heath. Assistant-Physicians: Dr. Arthur W. Edis, Dr. Squarey. Operations: Saturday mornings, 9.30. Third-year's men and Practitioners may attend the practice and operations by presenting their card.

BRITISH LYING-IN HOSPITAL, Endell Street, W.C.—Physicians: Drs. Heywood Smith, Arthur Edis, and Wiltshire. This institution receives women only as midwifery pupils.

THE HOSPITAL FOR SICK CHILDREN, Great Ormond Street.—Physicians: Drs. West and Dickinson. Assistant-Physicians: Drs. Gee, W. B. Cheadle, J. J. Phillips, John Murray, and R. J. Lee. Surgeons: Messrs. T. Smith, F. Howard Marsh, and Mr. J. W. Haward.

BELGRAVE HOSPITAL FOR CHILDREN, 1 Cumberland Street, S.W.—16 beds. Physicians: Drs. Anstie and Hope. Surgeon: Messrs. Brodhurst and Pick.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark-bridge Road.—Founded and endowed in 1869, by Baron Ferdinand de Rothschild. 100 beds. Physicians: Drs. C. Hilton Fagg, C. Kelly, E. B. Baxter, and F. Taylor. Surgeons: Messrs. Morratt Baker and H. G. House. Resident Medical Officer: James B. Ball, M.B. Lond.

THE LADIES' MEDICAL COLLEGE.—Established by the Female Medical Society for Teaching Educated Women the Theory and Practice of Midwifery and the accessory branches of Medicine. Details may be obtained by letter from the Lady Secretary, 164 Great Portland Street.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, Bloomsbury Square, London, W. C.—School of Pharmacy. The session will commence October 1st, and extend to the end of July. Lectures on Chemistry and Pharmacy will be delivered by Professor Redwood on Monday, Tuesday, and Wednesday, at 9 a.m. Also lectures on Botany and Materia Medica, by Professor Bentley: the first and second parts of this course will be delivered at 17 Bloomsbury Square, on Friday and Saturday, at 9 a.m.; the third part of the course, on Systematic Botany, will be delivered at the Royal Botanic Gardens, Regent's Park, on Friday and Saturday, at 9 a.m. The Laboratory, under the direction of Professor Atfield, is open from 10 a.m. to 5 p.m. daily, excepting Saturdays, when it is open from 10 a.m. to 2 p.m. Students may enter at any period during the session.

SOUTH LONDON SCHOOL OF CHEMISTRY AND PHARMACY, 231 and 285 Kennington Road, S.E.—Director, Dr. Muter. Classics, Mathematics, Chemistry, Physics, Botany, Materia Medica, and Pharmacy are all taught.

ROYAL VETERINARY COLLEGE, Great College Street, Camden Town.—The lectures will commence at this institution on Tuesday, the 1st of October. The anatomy, physiology, and pathology of the horse and other domesticated animals are regularly and scientifically taught in the institution. The late Professor Spooner's chair has been worthily filled by Professor Simonds. Perpetual fee to all the lectures, with Infirmary practice and anatomical demonstrations daily, twenty-five guineas. Matriculation fee, one guinea.

ENGLISH PROVINCIAL MEDICAL SCHOOLS.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, NEWCASTLE-ON-TYNE.—The winter session will commence on Tuesday, October 1st, at 2 p.m., when the Very Reverend the Dean of Durham, Warden of the University, will present the Dickinson Scholarship, the Medals, Certificates of Honour, &c., to the successful Candidates.

Fees for Lectures.—Fee for all the Lectures, except the course of Practical Pharmacy, 50 guineas.

Medical Scholarship in the University of Durham.—A Medical Scholarship, of the annual value of £25, will be awarded after examination, commencing on Tuesday, October 8th, 1879, and open to all Candidates who have been duly registered at Durham as Students in Medicine.

The Scholarship is tenable for four years by a Student pursuing his Medical studies at Newcastle, and not of sufficient standing to proceed to a Licence in Medicine.

Dickinson Memorial Scholarship.—The friends of the late John Dickinson, M.B., Durham, who was Medical Officer to the Universities' Mission to Central Africa, in 1866, desirous of testifying their admiration for his character, and their sorrow at his untimely death, subscribed a sum of money, the annual interest of which, amounting to £15, is awarded annually, as "The Dickinson Memorial Scholarship."

LEEDS SCHOOL OF MEDICINE.—*Lecturers in the School:* Anatomy, James Seaton, L.R.C.S., Robert T. Land, M.D., M.R.C.S., John A. Nunneley, M.B., M.R.C.S. Physiology (including Practical Physiology), C. J. Wright, M.R.C.S., James Walker, M.R.C.S. Medicine, John D. Heaton, M.D., F.R.C.P., T. C. Allbutt, M.A., M.D., F.L.S. Morbid Anatomy, John E. Eddison, M.D. Surgery (including the Practical Course), Claudius G. Wheelhouse, F.R.C.S., T. Pridgin Teale, M.A., F.R.C.S., T. R. Jessop, F.R.C.S. Mental Diseases, J. Crichton Browne, M.D., F.R.S.E. Chemistry, J. Chapman Wilson, F.C.S. Materia Medica, John E. Eddison, M.D. Midwifery, W. Hall, M.R.C.S. Forensic Medicine, Thomas Scattergood, M.R.C.S. Botany, Edward Atkinson, F.L.S. Comparative Anatomy, C. G. Wheelhouse, F.R.C.S., T. C. Allbutt, M.A., M.D., F.L.S. Demonstrations of Anatomy, R. P. Oglesby, M.R.C.S., Edmund Robinson, M.R.C.S.

The Composition fee, for attendance upon all the required courses of School Lectures is 44 guineas, and may be paid at once or in two instalments at the commencement of the first and second Winter Sessions.

The fee for the Comparative Anatomy course is not included in the Composition fee.

Entrance fee to Library and Reading Room, £1 1s., to be paid by all Students on entrance.

Practical Physiology.—In accordance with the regulations of the Royal College of Surgeons, this course is carried out in conjunction with the Lectures on Physiology. It consists mainly of a series of Microscopical Demonstrations of Animal Structures, in which every member of the class is enabled to familiarize himself with the practical use of the microscope and the manipulations necessary for preparing specimens for examination.

A limited number of microscopes is provided. It is, however, very desirable that every student should possess an instrument of his own.

The Large Laboratory is devoted to the use of Students, and has sufficient space for 28 or 30 Students to work at one time. Each table is supplied with drawers and closet, gas, water, sink, and separate frames of re-agents.

General Chemical Students.—The Laboratories are open daily, under the direction of Mr. Wilson, for the instruction of General Students in Chemical Manipulation, Technical Chemistry, and all branches of analysis; and also for the use of gentlemen wishing to pursue special chemical researches.

West Riding Lunatic Asylum, Wakefield.—Dr. J. Crichton Browne, F.R.S.E., the Medical Director of the West Riding Lunatic Asylum, lectures on Mental Diseases during the Summer Session. The Systematic Lectures are given at the School, and the Clinical Lectures at the Asylum, which now accommodates 1,500 patients. It is needless to point out how great and unusual an advantage is here presented to those inclined to make themselves conversant with the improvement made of late years in the treatment and management of the insane.

The Leeds Fever Hospital.—Much valuable experience

in the diagnosis and treatment of fevers is to be gained in this Hospital, which is capable of receiving 80 patients.

BRISTOL SCHOOL OF MEDICINE.—The Winter Session will commence on Tuesday, October 1st, 1879.

The present building was completed and occupied in 1858, and is furnished with many modern improvements. It contains 140 beds, in addition to which the out-patient department affords a large and instructive field of observation. The number of patients treated during the past year was 15,127.

Guthrie Scholarship.—A Medical Scholarship of £15, founded by the late Rev. Canon Guthrie, is awarded annually to the most diligent Student attending the Medical Practice of the Hospital.

Clarke Scholarship.—A Surgical Scholarship of £15, founded by H. M. Clarke, Esq., of London, is awarded annually to the most diligent Student attending the Surgical Practice of the Hospital.

Sanders Scholarships.—A Scholarship, founded by the late John Naish Sanders, Esq., and consisting of the interest of £500, is awarded annually to the most proficient Student in Medicine and Surgery. Two of these Scholarships will be offered for competition in 1879.

Obstetric Medicine.—Dr. Swayne attends on Mondays and Thursdays, at half-past two o'clock, to see patients affected with uterine diseases.

Dental Surgery.—Mr. Parson attends on Mondays and Thursdays, at nine o'clock, and will give instruction in Dental Surgery.

Morbid Anatomy.—The *Post-mortem* Examinations are conducted, and Pathological Demonstrations given, by each Medical Officer at two o'clock. The Museum contains numerous interesting and instructive specimens.

MANCHESTER ROYAL SCHOOL OF MEDICINE, incorporated with the Owens College.—Connected with this school are Museums of Human and Comparative Anatomy and Materia Medica, and a Chemical Laboratory. The Winter Session will open on the 1st October, and attendance will be given daily from 12 till 2, at the Medical School, 10 Faulkner street, up to the 14th October, for Registration. Three Scholarships of the value respectively of £20, £15, and £10 are open annually to the competition of perpetual students; and Prizes for general proficiency, and Certificates of Honour for regular attendance and good conduct are awarded at the end of each Session. A Composition fee of 40 guineas admits to the whole of the Lectures, and a further Composition fee of 40 guineas to the Hospital Practice of the Royal Infirmary. Prospectuses may be obtained from the Registrar at the College.

SHEFFIELD SCHOOL OF MEDICINE.—The Introductory Address will be delivered by T. H. Morton, Esq., and the prizes distributed on October 1st.

SHEFFIELD GENERAL INFIRMARY.—Physicians, Dr. de Bartolomé, Dr. Law, and Dr. Frank-Smith. Surgeons, Mr. Barber, Mr. Favel, and Mr. Parker, F.R.C.S.

The Infirmary contains 160 beds for in-patients. Shortly to be increased to 200. The new wards are now nearly completed, and will be opened in the course of the year. A new museum and pathological theatre will be added immediately.

The fees for perpetual attendance at the Infirmary are £15 15s. for Medical, £21 for surgical practice.

UNIVERSITY OF CAMBRIDGE.—*Faculty of Medicine.*—The following lectures will be delivered in the Course of the Academic year:—Experimental Physics, Prof. Maxwell. Chemistry, Prof. Living. Practical Chemistry, Prof. Living and Dr. Hicks. Anatomy and Physiology, Prof. Humphry. Practical Anatomy, Prof. Humphry and Dr. Wilson. Practical Physiology, Dr. Michael Foster. Zoology and Comparative Anatomy, Prof. Newton. Botany, Prof. Babington. Materia Medica, Prof. Fisher or Dr. Latham. Pathology, Dr. Bradbury. Medicine, Prof. Paget, M.D. Clinical Medicine, Drs. Paget, Latham, and Bradbury. Clinical Surgery, Mr. Lestourgeon, Dr. Humphry, and Mr. Carver.

ADDENBROOKE'S HOSPITAL, CAMBRIDGE.—Clinical Lectures in Medicine and Surgery in connection with the Cambridge Medical School, are delivered at this hospital twice a week during the academic year; and practical instruction in medicine and surgery, in the wards, is given by the physicians and surgeons daily, during the vacations, as well as term time.

QUEEN'S COLLEGE, BIRMINGHAM.—Two Warneford Scholarships and the Sands Cox Prize, value £20, are awarded annually after examination. The Warden's Prize, value £5 5s., is awarded annually to the most proficient student of the first year. The Percy Prize is awarded for proficiency in German, and class prizes and certificates of honour are given in each class after examination. Students may reside within the College, where they will be provided with rooms and board, and be under the supervision of the warden and resident tutors. Fee £50 per annum. In the Arts Department, junior students are prepared for any of the preliminary examinations of the licensing boards. The University of London holds an annual matriculation examination within the walls of the College in the month of June, for students residing in Birmingham and the neighbourhood. Hospital practice may be attended at either the General Hospital or the Queen's Hospital, which are equidistant from the College.

GENERAL HOSPITAL, BIRMINGHAM.—Physicians: Dr. Bell Fletcher, Dr. Russell, Dr. Wade, Dr. Foster. Surgeons: Mr. Baker, Mr. Pemberton, Mr. Bartleet, Mr. Goodall, and Mr. Jolly. Fees, Medical and Surgical practice, six months, £10 10s.; one year, £15 15s.; perpetual, £31 10s. Clinical lectures are delivered by the physicians and surgeons every week during the session. Special clinical courses, with demonstrations, will also be given on the following subjects—viz., diseases of women, stethoscopy, laryngoscopy, ophthalmoscopy, dermatology, bandaging, and minor surgery, and clinical microscopy. The following resident appointments, with board, lodging, and washing, are filled up from amongst the students, without extra fee—viz., resident Medical assistant, tenable for twelve months; resident surgical assistant, tenable for twelve months; two resident dresserships, tenable for six months. Extern clerks and dressers are also appointed without extra fee. Prizes in books or money (at the discretion of the Medical Board) to the value of £25 are given annually.

THE QUEEN'S HOSPITAL, BIRMINGHAM.—Incorporated by a special Act of Parliament as a clinical hospital.

The wards are visited daily, and clinical lectures and instruction are delivered by the physicians and surgeons. There are special lectures and demonstrations on diseases of the skin, diseases of women and children, orthopedic surgery, venereal diseases, bandaging, and the application of surgical apparatus.

Clinical prizes of the value of £31 are awarded annually. Composition fee for the Medical and surgical practice, £31 10s.; one year's attendance, £15 15s.; six months' attendance, £10 10s.; special department for midwifery and diseases of women, £2 2s.; dental fee, optional, £1 1s.

LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE.—Four Exhibitions, value £31 10s. each, consisting of free board and residence in the Royal Infirmary for six months, with dresserships, on award of the Medical Board. Six dressers and six clinical clerks are elected quarterly. Pupils of the infirmary are admitted to learn pharmacy in the dispensing department for six months. The surgeons of the infirmary will award, in May, 1873, a prize of the value of £5, for the best report of twelve surgical cases occurring in the infirmary.

Fees.—For six months' Medical practice, five guineas; twelve months, six guineas; surgical, six guineas for six months, eight guineas for twelve months (this includes admission to the practice of the Lock Hospital adjoining the infirmary); perpetual Medical and surgical practice, thirty-two guineas.

The hospital contains 300 beds, including wards, with 40 beds, for the treatment of diseases of women.

LIVERPOOL NORTHERN HOSPITAL.—146 beds. A special ward for the diseases and accidents of children. Clinical lectures are regularly delivered by the physicians and surgeons during the winter and summer sessions. Instruction in morbid anatomy is given by the Medical staff. A class will be formed for instruction in bandaging and the minor operations of surgery. Clinical clerkships and dresserships are open to all the students, without additional fee. Clinical prizes will be awarded at the termination of the winter session.

Fees for Hospital Practice and Clinical Lectures.—Perpetual, twenty-five guineas; one year, ten guineas; six months, seven guineas; three months, four guineas.

One resident pupil received; fee, sixty guineas per annum. Attendance on the practice of this hospital qualifies for all the examining boards.

LIVERPOOL SOUTHERN HOSPITAL.—200 beds. Clinical Lectures, with special instruction in the employment of Medical and Surgical Instruments, in Bandaging, and in Minor Surgery, are regularly given during winter and summer sessions. Accommodation for resident pupils. The lectures and practice are recognised by all the Examining Boards.

Fees for Practice and Lectures.—Perpetual, twenty-five guineas; one year, ten guineas; six months, seven guineas; three months, four guineas.

For further particulars, apply to the house-surgeons.

COLLEGE OF PHYSICAL SCIENCE, NEWCASTLE-ON-TYNE.—A new building has been erected in Newcastle-on-Tyne for the teaching of physical science the first of the kind in this kingdom. The names of the professors are as follows:—Professor W. S. Aldis, M.A., will teach Mathematics; Professor A. S. Herschell, B.A., F.R.A.S. Experimental Physics; Professor A. Freire-Marreco, M.A., Chemistry; Professor David Page, LL.D., Geology. Various exhibitions and scholarships will be awarded at the close of the session.

It is proposed to found also a Chair of Natural History in connexion with this College as soon as funds will permit.

WOLVERHAMPTON AND SOUTH STAFFORDSHIRE GENERAL HOSPITAL.—200 beds.—The practice of the hospital is very extensive and varied; the number of cases annually treated being large and important. Practical instruction in surgery to first-year's students, and dresserships for students after two years' professional education, both in accordance with the Royal College of Surgeons of England, may be obtained at this hospital; also clinical clerkships.

SCOTTISH INSTITUTIONS.

The fees for degrees in all four of the Scottish Universities are uniform—viz.: M.B., £15 15s. (being £5 5s. at each of the three examinations); C.M., £5 2s. (in addition to the fees of M.B.); M.D., £5 5s. (in addition to the fees for M.B.); and £10 3s. for Government stamp.

University of Edinburgh.—This is a teaching as well as a qualifying body, and the other facilities are as complete as that of medicine. The University confers the degree of M.D., and M.B., as well as that of C.M., and so affords its graduates the opportunity of obtaining, at the same time, a surgical, in addition to the Medical diploma. The C.M. is not conferred on any one who does not take at the same time the M.B. For the degrees of M.B. and C.M., four years of professional study must be completed after passing a preliminary examination recognised by the Medical Council. A Degree in Arts in any British University exempts from the preliminary examination. Of these four years, one must be passed in the University of Edinburgh, and one other either in that or some other University entitled to confer the degree of M.D.

The University recognises the course of lectures of extra-academical teachers in Edinburgh, subject to certain regulations.

University of St. Andrew's.—This University confers the degree of Master in Surgery (C.M.), as well as the degrees of Bachelor and Doctor of Medicine. For many years the University did not require residence, and large numbers of Medical men resorted to it in order to obtain the Doctorship by examination only. In this the University closely assimilated itself to the University of London, which is exclusively an examining body. The large number of practitioners who obtained the degree after an examination extending over three or four days, attests the wisdom of a policy which was almost reversed by the University Commissioners. Only ten persons per annum can now obtain the St. Andrew's Degree without residence. There are not a few of the old graduates who look upon this policy as retrograde and illiberal. The University of London maintain its position without requiring academical residence, and no one can doubt that the University of St. Andrew's might have pursued the same course with great success, and by so doing conferred a benefit on the Profession. Those who have not now fulfilled their course in a University must either go to the University of London or forego a degree. The London University compels matriculation before commencing hospital study. Only a relaxation of this rule can secure to all who desire it the opportunity of being examined for a degree.

University of Aberdeen.—This is a large teaching body, as well as one entitled to confer degrees in all the faculties. The curriculum required for Medical degrees is the same as that of the University of Edinburgh. Thus, four years of professional study, after passing a preliminary examination, is essential. One year must be passed at Aberdeen. The lectures qualifying for this and other examining bodies are delivered by the Professors in the University.

University of Glasgow.—This is a large teaching as well as examining body. The same degrees are conferred as in the Universities of Edinburgh and St. Andrew's. The course of study and regulations to be observed by candidates are the same as those of the University of Edinburgh, one year's compulsory residence at the University of Glasgow being required instead of at Edinburgh. The examinations are conducted by the Professors of medicine, together with the three Assessors appointed by the University Court. The lectures qualifying for the degrees are delivered by the Professors in the University, and the hospital practice is attended at the Glasgow Royal Infirmary.

Royal College of Physicians of Edinburgh.—This, like its London sister, is exclusively a licensing body, though, since the arrangement for the double qualification has been carried out, it may possess some additional control over the teaching at Surgeons' Hall. By this arrangement students who have filled the prescribed curriculum may pass the joint examination of this College and the Royal College of Surgeons, and obtain the two diplomas. They can thus at once register both a Medical and surgical qualification.

The Fellowship is conferred only by election, and no one can be ballotted for until he has been a member for one year.

The Membership is conferred on licentiates of a College of Physicians, or graduates of a University, who are twenty-four years of age, and satisfy the College of their knowledge of Medical and general science.

THE LICENCE.—The regulations are nearly the same as those for the Joint Examination for the Scotch Double Qualification.

Royal College of Surgeons of Edinburgh.—The Fellowship is conferred only on persons who have obtained a diploma from this or one of the Colleges of Surgeons of England or Ireland, or the Faculty of Physicians and Surgeons of Glasgow, and who are twenty-five years of age. At the election, three-fourths of the votes are required to be in the candidate's favour, and he has to promise to maintain the privileges of the College and obey its laws. Fellows are forbidden to keep open shops, to be connected with secret remedies, or to suffer their names to be used in indelicate advertisements or publications.

THE LICENCE.—The regulations are nearly the same as those for the Joint Examinations, conducted by the Colleges of Physicians and Surgeons.

Faculty of Physicians and Surgeons of Glasgow.—This body has similar powers to those of the Royal College of Surgeons of Edinburgh, and its regulations for Licence and Fellowship correspond. It has also the same arrangement with the Edinburgh College of Physicians for a double diploma.

The Scotch Double Qualification.—As already stated, the Royal College of Physicians of Edinburgh has made arrangements with the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow, by which, after one series of examinations, the successful candidate receives two diplomas, and is thus able to register a Medical and a surgical qualification under the Medical Act, thus:—

Lic. Roy. Coll. of Phys. Ed., and Lic. R. C. S. Edin., or Lic. R. Coll. of Phys. Ed., and L. Fac. Phys. and Surg. Glas., as the case may be.

The principle on which the joint examinations are conducted is a simple compromise by which the College of Physicians takes exclusive charge of the examination in medicine; the College of Surgeons or the Glasgow Faculty, as the case may be, of the examination in surgery; while the examination in subjects common to both medicine and surgery is conducted by a Board, in which each of the bodies is represented.

It is proper to state that such arrangements as these were contemplated by the Medical Act and authorized by Section XIX., while those under consideration were sanctioned by the Medical Council on the 7th August, 1859.

Candidates for the double qualification having fulfilled the prescribed curriculum are subjected to two professional exami-

nations. The preliminary examination for future students must be passed before commencing professional study, and in other respects be in accordance with the recommendations of the Medical Council.

Anderson's University, Glasgow.—This is exclusively a teaching body. It offers excellent opportunities for acquiring a complete Medical education, and the expenses are very much below those of any other institution. The fame of Glasgow as a place for clinical instruction has long been known, and this school affords the means of dissection, and the pursuit of other practical knowledge throughout the year. Hospital practice is attended at the Glasgow Royal Infirmary.

Edinburgh Royal Veterinary College.—This highly useful Institution, established so long back as 1823 by Professor Diok, is now under the Principalship of Professor W. Williams, F.R.S.E., author of the new and comprehensive treatise on *The Principles and Practice of Veterinary Surgery*. The present year is the jubilee of the College, and its fiftieth session will be opened on Wednesday, October 30th, with an Introductory Lecture by Professor Dewar. For fees, &c., apply to Professor Williams at the College.

MEDICAL EDUCATION IN IRELAND.

THE CAREER OF THE IRISH STUDENT.

THE practice of the Profession in Ireland, though not nearly as remunerative as in England, still affords a certain prospect to any Medical man who is content with modest independence. Irish Medical men pride themselves on holding a higher social position than the English general Medical practitioner. They are entitled to meet the gentry of their locality on terms of equality, and it is not necessary or usual for them to endanger their prestige by the adoption of the trading or Christmas bill system which obtains elsewhere. In fact, what they lose in income they gain in rank.

In order to put the career of the Irish Student as plainly as possible, we narrate the progress of an ideal person, from the day on which he takes his first step towards medicine to the hour of his issue from the cocoon of his studentship, a fully-developed surgeon.

The parents and guardians of Master Robert Sawyer have, after much discussion, decided that he shall be a doctor. He has had a moderate amount of schooling, at least the very moderate amount which is essential for the Medical prelimi-

mary examinations, and his father is ready to expend about £130 on his Medical education, that sum being divided over four years, or paid down in order to secure the advantage of a considerable saving.

THE CHOICE OF UNIVERSITIES AND COLLEGES

will depend on various circumstances, and on the aspirations of Master Sawyer. If he's intended to make a fortune and enlighten his generation as a metropolitan practitioner, and if money and education are plenty, he will probably take University degrees in Arts and in his profession. If the attainment of good professional rank on moderate terms be desired, the College of Surgeons and College of Physicians will serve every purpose. For University Degrees it is to be remembered the student must undertake the prolonged study of classics and science, in addition to his Medical, Surgical, and Anatomical studies, and he will have to pay a considerable sum for this course of teaching, and, in the case of the Queen's University, to live for a certain period at the College where he studies. But if he is content to face the expense and labour he will enter the Profession with all the prestige of an educated gentleman. In fact, the question whether he will or will not lay out for himself a University graduation in Arts and Medicine depends principally on whether he has money and time to give to it, and whether or not he means to practice in the Metropolis. The Queen's University places at the disposal of the student a cheap University Degree, and thereby attracts many applicants, but it is burthened by the necessity for the residence of the student for a time at Galway, Cork, or Belfast, and, in the question of prestige, can hardly pretend to compete with the time-revered University of Dublin.

The Colleges of Surgeons and Physicians of Ireland confer qualifications which may stand well beside any in the United Kingdom, and as they do not require either residence or anything more than a single Arts examination, they continue to be the licensing bodies for the rank and file of the Profession in Ireland. If a student contemplates provincial practice—the Army or Navy—or a dispensary, he will most probably take the usual licenses from the two Colleges.

THE CHOICE OF SCHOOLS.

It must not be supposed that a student who intends taking a degree or diploma in any College must take his lectures in the school attached to that College, if there be one. On the contrary, with few exceptions, all certificates of attendance on lectures are interchangeable, and a student, no matter what Medical school he may have studied in, will be admitted to any University or College. To this rule there are some exceptions. The University of Dublin does not admit any candidate who has not taken one year or annus medicus in their School, and the Queen's University insists on certain courses being attended in one of the Queen's Colleges.

There is in some cases a sort of semi-official connexion between certain Colleges and Hospitals, as between Trinity College and Sir Patrick Dun's, between the College of Surgeons and City of Dublin Hospital, and between the Catholic University and Mater Misericordiæ Hospital; but this connexion only exists because the Professors of the College are in many instances officers of the Hospital, and it confers no special immunity or privilege on the student of such Hospital.

The choice of a School, Hospital, and College having been made, Master—now *Mister*—Sawyer is perhaps sent to those to pass his

PRELIMINARY EXAMINATION

in general education, but if he be either lazy or ignorant, he may adjourn that unpleasant process, *de die in diem*, until the eve of his final qualification as a Surgeon, when, if he does so, he will find himself in possession of a mental muddle of latin and physic. The preliminary examination is, however, not to be feared.

We strenuously advise the parents of the student to insist on his passing his preliminary education before he enters a Medical school or hospital, and thus the student will relieve his mind of the apprehension of a future examination, which he will assuredly put off to the last moment if he can.

The preliminary examination (of the subjects of which details will be found in the official regulations of each College) having been passed or postponed, Mr. Sawyer comes to town to begin work.

He may do so either (1) on his own account, or (2) he may become voluntarily a pupil of some Medical man, usually a teacher or hospital surgeon, who can assist him in his studential course. This is by no means a requirement of any of the Colleges; it is purely a matter of option. Should the student pursue the first course, he usually comes to town, takes a lodging close to his School and Hospital, either by himself or in companionship with some *chum*, and either arranges to maintain himself or to board with his landlady. There is, of course, every degree of expense and comfort, but we should say that reasonable yet frugal living may be had in Dublin at about 10s. per week for lodging, and £5 to £6 per month for maintenance.

We would here, as a matter of private judgment, remark that it is better for parents to have board provided on a good substantial scale by the house. Young men are too apt to spend their money on luxuries or extravagancies, and make up the deficit by using insufficient food, to the great injury of the health.

COST OF EDUCATION.

Should the student proceed on his account, the lectures necessary for the L.R.C.S.I. will amount to £65; hospital attendance about £25; lying-in hospital from £4 4s. to £7 7s. These, with the diploma fee of £26 5s., represent the essentials. The sum of £50, paid down at the commencement, is taken by the College of Surgeons as payment in full for all lectures requisite, and all the hospitals allow a considerable discount. Thus, the absolute payment will amount to somewhere about £83, taking the minimum mode of payment. In addition to this sum are to be considered the payments for "grinding" or "coaching," as the Londoners call it, a process by no means necessary to any industriously inclined student, particularly under the new and more practical *régime*, where "tips" will be less useful than the practical knowledge and the fall of the mere coached be rendered probable by being asked to put his ideas on paper, examine his patient, make his diagnosis, and order his prescription. The fixed sum is at present, for private teaching, £15 15s. for the surgical and Medical qualifications, and £5 5s. for pharmacy, &c. Should the candidate "grind" for the army and navy examinations, a fee varying from £10 10s. to £21 is, we believe, usual. Should the candidate perform operations on the subject as a practice, they will cost something extra. So, that, assuming the extras or voluntary costs are incurred, the total will vary say from £114 to £120 on a moderate scale; it is of course to be expected that pupil holders should have some extra payment, we therefore might name for them £140 guineas.

PAYMENT OF FEES.

If Mr. Sawyer becomes an apprentice, he need trouble himself nothing about his payments. If he is his own manager, he must enter his name with the Secretaries of the School and Hospital, and pay for the Lectures and Hospital he intends to take out. If he is wise he will not adjourn the majority of his lectures, as he may, to the next year, but will take in his first year a full third of his curriculum. He is supposed to pay the Professor's fee or Hospital fee in full on entering his name, but few students do so, and many, we are sorry to say, are in the habit of entering for the minimum allowable number of lectures, and paying the minimum allowable proportion of the fee, putting off the attendance perhaps for ever, cer-

tainly until the last moment, and adjourning the payment until they must take up the certificates.

By a most objectionable laxity of system a student may get credit for one of his four years of attendance by paying a couple of guineas for dissections, and he may think himself safe in doing so if money be scarce; but if he does not pay his full third or fourth of the fees each year it often happens that he has to put off his examination from year to year—perhaps for ever, for want of the money to pay the accumulated fees of previous years.

The entry of names and commencement of study is supposed to date from the 1st of October in each year, but really does date from the 1st of November, and may be delayed by the dilatory until the 25th of the same month.

Mr. Sawyer then begins work, attending Hospital each morning at nine o'clock, and occupying his day from half-past eleven to five between lectures and dissections. His holidays—if the term be not ignoble—are a fortnight at Christmas and a week at Easter, and he finally returns home at the end of July.

The progress of each year is the same, except that he usually devotes more attention to "grinding," dissection, and hospital dresserships, and less to lectures in his later years of study, and after the expiration of his third session, his student-life, whether it begin in laziness and end in hurry and incompetency, or whether it commence in diligence and end in the confidence of proficiency, ends with the last examination, and he goes forth into the world either an ignoramus or a reliable surgeon, whichever his choice may have been.

PRIVATE TEACHING, OR "GRINDING."

The classes for private instruction, or "grinding," as it is technically and generally called, are carried on in Dublin with universality and success.

As a rule, all private teachers are connected with schools of medicine, and are in every respect highly qualified, many of them being also hospital physicians or surgeons, and therefore in a position to afford the special advantages in the way of clinical instruction to their pupils.

Grinding is followed in two methods—namely, on what are commonly known as the "public" and the "private" plans. In the former, a number of gentlemen, varying in different schools from two to four, associate themselves into a firm, or co-partnership, and each man, selecting particular branches, gives instructions in those only. For these classes a pupil may enter at any period of his course, by payment of a certain sum; but as the amount demanded generally is the same at whatever period of his course the student joins the class, and as he is taught for it until he obtains his degrees, it is usual to enter as early as possible, so as to secure the largest amount of instruction; but while there can be no objection to entering the name at the earliest period, we strenuously advise the student not to devote himself to "the grind" for his first, or even for his second, year of study, but to apply himself to his hospital and dissecting.

As an example of the method pursued with regard to these "public grinds," we cannot do better than give the following extract, treating on the subject, from the book of instructions and information for students, issued by the Professors of the School of Surgery of the Royal College of Surgeons:—

"In connection with the School of the College, for many years four of the senior demonstrators have jointly instructed private classes in all the subjects required for the professional examinations of the licensing bodies.

"In these classes, students are taught so as to insure that the subject shall be thoroughly understood by them.

"They are divided into senior and junior, according to the course of study, capacity, and diligence of the pupil.

"The subjects are—

"Practice of Medicine, Midwifery, and Surgery.

"Anatomy and Physiology.

"Materia Medica, Botany, and Chemistry.

"At least four classes are held daily (besides those for junior) at such times as do not interfere with the lectures at the School, each lasting for one hour—part of these classes being in the evening, for those who cannot otherwise attend. The fee is £18 18s., half of which is paid at the time of entry, the remainder when the diploma or degree is obtained.

"Should Materia Medica, Botany, and Chemistry not be required, £15 15s. for all the other classes divided in a similar manner.

"The fee for Materia Medica alone is £5 5s.

"For those who have already obtained professional qualifications, there are classes held for the army and navy medical competitive examinations, when special instruction is given in all the subjects required. Fee for these classes varies from £10 10s. upwards, according to the length of time required."

"Private grinding" is simply an arrangement quite independent of the other. A student who may, or may not, be a member of another class, wishes for instruction; he goes to a "grinder," who, for a sum of, usually, £3 3s. per month, instructs him in the required branches of his profession. As a rule, each teacher devotes himself to particular subjects: thus, one gentleman grinds in, perhaps, Anatomy, Physiology, Surgery, and Medicine, another in Surgery alone, whilst a third will teach Chemistry, Botany, and Materia Medica.

In some schools slight differences of system are obtained: thus, a pupil may enter for the subjects he requires by paying a fixed sum, which entitles him to attend for the length of a session, but gives him no further claim on the attention of his grinder.

Each of these plans will be perceived to have its own particular advantages. By entering for public grinding, a pupil, on the payment of a moderate sum, secures that he shall be taught all his necessary subjects; while, on the other hand, if he enters for private grinding, he may, from being in a smaller class, secure a larger amount of individual attention; but does so at an increased expense, and must pay separately for the various branches of his teaching.

It does not require a very arithmetical head to see the difference between paying—say, £15 15s. for being taught for four years at least, in Anatomy, Physiology, Medicine, and Surgery, and paying £3 3s. per month for instruction in Anatomy and Physiology, and the same for Surgery or Medicine, or that the instruction obtained by a private or personal catechism is more valuable than in a public class.

In the School of the Royal College of Surgeons, the senior demonstrators are associated together for the purposes of private teaching, each gentleman giving instruction in special branches.

Mr. Croly, } in Surgery, Anatomy, Physiology,
Dr. Stoker, } and Medicine.

Dr. Kilgarriff { Materia Medica, Chemistry, and
Botany.

Dr. W. Handsell Griffiths, Librarian at College of Surgeons, gives notice that he will meet his Classes for Professional Examinations on the 1st of October.

Drs. Stoney and Wheeler, Demonstrators in the School, are also joined in private teaching.

Dr. Ormsby also teaches several of the above subjects.

In the Trinity School—

Dr. Foot, } Anatomy, Physiology, Surgery, and
Dr. Finney, } Medicine.

Dr. Little, }
Dr. W. Smith—(Chemistry and Materia Medica.

Dr. Collins, } Anatomy, Physiology, Surgery, and
Medicine.

In the Carmichael School—

Dr. Corley, } Anatomy, Physiology, Surgery, and
Dr. Kelly, } Medicine.
Dr. Cameron, } Materia Medica, Chemistry, and
Botany.

In Steeven's Hospital and School—

Mr. Swan,
Dr. Bookey,
Dr. Bell, } Chemistry, Botany, and Materia
Medica.
Dr. Tweedy—Preliminary Examination.

In Catholic University private teaching is conducted by
Drs. Hayes, Coppinger, and Nixon.

In Ledwich School—

Dr. Ledwich and
Dr. Mason, assisted by
Dr. Ward,
Dr. Corry,
Dr. Battersby.

REGULATIONS AND BYE-LAWS OF LICENSING BODIES IN IRELAND.

UNIVERSITY OF DUBLIN.

REGULATIONS OF THE SCHOOL OF PHYSIC.

Regius Professor of Physic—William Stokes, M.D., D.C.L.,
F.R.S.

Regius Professor of Surgery—Robert Adams, Ch.M.

University Professor of Anatomy and Surgery—Benjamin G.
M'Dowel, Ch.M.

University Professor of Chemistry—James Apjohn, M.D.,
F.R.S.

University Professor of Botany—E. Perceval Wright, M.D.

Professor of Surgery in Trinity College—Robert W. Smith,
Ch.M.

University Anatomist—Edward H. Bennett, Ch.M.

Erasmus Smith's Professor of Natural Philosophy—Rev. John
Lealie, M.A.

University Lecturer in Operative Surgery—Richard G.
Butcher, M.D.

University Examiner in Ophthalmic Surgery—Henry Wilson,
F.R.C.S.I.

King's Professor of Institutes of Medicine—Robert Law, M.D.

King's Professor of Practice of Medicine—William Moore,
M.D.

King's Professor of Materia Medica and Pharmacy—Aquila
Smith, M.D.

King's Professor of Midwifery—Edward B. Sinclair, M.D.

Professor of Medical Jurisprudence—Robert Travers, M.B.

The following Degrees and Licences in Medicine and Sur-
gery are granted by the University of Dublin :—

1. Bachelor in Medicine. 2. Doctor in Medicine. 3. Mas-
ter in Surgery. 4. Licentiate in Medicine. 5. Licentiate in
Surgery.

Matriculation.

Every student must be matriculated by the senior lecturer,
for which a fee of five shillings is payable; but he need not
have his name on the College books, or attend any of the aca-
demical duties, unless he desire to obtain a Licence or Degree
in Medicine or Surgery. No student can be admitted for the
Winter Courses after the 25th of November.

QUALIFICATIONS FOR DEGREES AND LICENCES.

Bachelor in Medicine.

Candidates must be graduates in Arts, and may obtain the
degrees at the same commencements as the B.A., or at any
subsequent one. The Medical education of a Bachelor in
Medicine is of four years' duration, and comprises the follow-
ing lectures :—

Winter Courses.—Anatomy and Physiology—Practical Ana-
tomy with Dissections—Surgery—Chemistry—Practice of Me-
dicine—Midwifery.

Summer Courses.—Botany—Materia Medica and Pharmacy
—Institutes of Medicine—Medical Jurisprudence.

Hospital attendance on a Medico-Chirurgical Hospital dur-
ing two courses of nine months each, with three consecutive

courses of clinical lectures. Also nine months' additional at-
tendance on a recognised hospital, and six months' Practical
Midwifery. Six months' Dissections and three months' La-
boratory Instruction in Chemistry are required.

Any of the courses may be attended at any recognised Medi-
cal school.

The schools recognised are—1. The School of the Royal
College of Surgeons of Ireland. 2. The Carmichael School.
3. The School of Steeven's Hospital. 4. The Ledwich School.
5. The Cecil Street School.

The fee for the *Licent ad Examinandum* is £5.

The fee for the degree of M.B. is £11.

Doctor in Medicine.

A doctor in medicine must be M.B. of at least three years'
standing, and requires no other qualification.

Total fees for this degree, £13.

Master in Surgery (a).

This degree can only be obtained by Bachelors of Art. The
curriculum is the same as that for the Licentiate in Surgery,
as given below.

Total amount of fees for the degree of Ch.M., £16.

Licentiate in Medicine.

Candidates for the licence in Medicine and Surgery must be
matriculated in Medicine, and must have completed two years
in Arts, and four years in Medical studies, and must pass an
examination in Arts, including Greek, Latin, English, and
Mathematics. The Medical course necessary for a Licence in
Medicine is the same as for the degree of M.B. A fee of £5 is
charged on taking the Licence. Licentiates in Surgery of the
Royal College of Surgeons, on passing the Art examination
will be admitted to examination for the Degree of Licence in
Medicine.

Fee for the *Licent ad Examinandum*, £5.

Fee for the Licence in Medicine, £5.

Licentiate in Surgery.

Candidates must have kept one full year in Arts, and will
be required to perform surgical operations on the dead sub-
ject. The curriculum extends over four years, and is as fol-
lows :—Two courses each of Anatomy and Physiology, and
Theory and Practice of Surgery; three courses of Demon-
strations and Dissections; and one course of each Practice of
Medicine, Chemistry, Materia Medica, Midwifery, Laboratory
Chemistry, Botany, Medical Jurisprudence, and one course
of Ophthalmic Surgery. Also attendance for three Sessions,
each of nine months, on a recognised hospital. Of the course
of lectures, which are of six months' duration, not more than
three can be attended during any one session. Any of the
above-named courses may be attended at any of the Medical
schools at Dublin. A fee of £5 is charged for the licence, and
£5 for the *Licent*.

ORDER OF STUDY RECOMMENDED.

No regular order of attendance on Lectures, Dissections,
and Hospitals is required; but the following course has been
approved of by the Board of Trinity College.

First Year.—1. Matriculation, 5s.; 2. Anatomy, £3 3s.;
3. Practical Anatomy, £3 3s.; 4. Dissections, £4 4s.; 5.
Chemistry, £1 11s. 6d.; 6. Botany, —; 7. Comparative
Anatomy, —; total, £12 6s. 6d.

Second Year.—1. Practical Anatomy, £3 3s.; 2. Dissec-
tions, £4 4s.; 3. Surgery, £2 2s.; 4. Physics, —; 5. Materia
Medica, £3 3s.; 6. Chemical Laboratory, £2 12s. 6d.; 7. Sir
P. Dun's Hospital, £9 9s.; total, £24 13s. 6d.

Third Year.—1. Practical Anatomy, £3 3s.; 2. Dissec-
tions, £4 4s.; 3. Surgery, £2 2s.; 4. Midwifery, £3 3s.; 5.
Practice of Medicine, £3 3s.; 6. Sir P. Dun's Hospital,
£9 9s.; total, £25 4s.

Fourth Year (b).—1. Institutes of Medicine, £3 3s.; 2.
Medical Jurisprudence, £3 3s.; 3. Practical Midwifery (Sir P.
Dun's Maternity), £3 3s.; 4. Ophthalmic Surgery (St. Mark's
Hospital), £2 2s.; 5. Sir P. Dun's Hospital, £9 9s.; total,
£21.

The following Books are recommended to Students of the
first and second years :—

1. *Anatomy.*—Harrison's Dublin Dissector.
Power's Surgical Anatomy of the Arteries.
Quain and Sharpey's Anatomy.
Kirk's Physiology.

(a) After the year 1874, candidates for this degree must be of the
standing of Master in Arts.

(b) Students wishing to dissect during the fourth year can obtain
this privilege on payment of One Guinea.

2. *Chemistry*.—Roscoe's Lessons on Elementary Chemistry. Attfield on Pharmaceutical Chemistry.
3. *Materia Medica*.—The British Pharmacopœia.
4. *Botany*.—Henfrew's Elementary Botany, by Masters; Part 1 and Part 2, Chapters 1 and 2 (a).
5. *Comparative Anatomy*.—
6. *Physics*.—Ganot's Treatise on Physics.

MEDICAL SCHOLARSHIPS.

Two Medical Scholarships are given annually, value £20 per annum each, tenable for two years, the examinations for which are held each year in June, in the following subjects:—Anatomy, Physiology, Chemistry, *Materia Medica*, and Botany.

Medical School Exhibitions.

The professors of the University school give three exhibitions annually; two senior, value £15 and £10, open to all students who have been three years attending the school. The subjects being—Practice of Medicine, Surgery, Pathology, and Forensic Medicine.

One junior, value £15—the time and subjects of examination being the same as those for the Medical Scholarship.

Expense of obtaining the degree of Bachelor in Medicine and Master in Surgery in the University of Dublin:—Lectures, £49 7s.; Hospitals, £33 12s.; Degree Fees, £32 = £115 4s.; Private Tuition, say £20; total £129 14s.

N.B.—As no degrees in Medicine or Surgery are conferred except upon graduates in Arts, the expense of the degree of Bachelor in Arts, amounting altogether to £33 4s., should be added to the foregoing, making the total cost something over 200.

The Board of Trinity College have recently passed orders:—

1. That three-fourths of the courses of lectures must be in all cases attended.
2. That the system of perpetual pupils be abolished.
3. That a daily roll be called by each Professor.
4. Students in Arts shall be entitled to attend one course in Botany, and to receive a certificate free of charge.
5. Candidates for degrees and licences in Surgery shall be required to attend one course only on Anatomy, for which he shall be charged three guineas.
6. The two courses delivered by the Professor of Surgery shall include practical instruction in Operative Surgery on the dead subject; and for each the professor shall charge four guineas.
7. The professor shall charge three guineas for the winter lecture in Chemistry.
8. Laboratory instruction shall be substituted for the second course of chemistry, hitherto delivered, for which the Professor of Chemistry shall charge five guineas.
9. Students in Arts may attend the Professors of Surgery and Chemistry, and receive certificates on payment of half the fees.
10. That after Shrovetide, 1868, all candidates in Medicine shall produce certificates in practical Midwifery, including at least six deliveries.

2. That Students of the School of Physic shall be required to attend the Lectures of Erasmus Smith's Professor, on Heat, Electricity, and Magnetism, and shall be entitled to receive Certificates of such attendance from the Professor, without the payment of a fee.

14. That Candidates for the Degree of Bachelor in Medicine shall be required to produce Certificates of Six Months' instruction in Practical Midwifery, with Clinical Lectures.

15. The following Regulations respecting the payment of Dissecting Fees, were finally adopted:—

(a). Students entering for Demonstrations and Dissections in the Dissecting Room of Trinity College, are required to pay the sum of Seven Guineas before the first day of December.

(b). Students entering for Dissections only, are required to pay Four Guineas before the first day of December.

(c). Students entering for Demonstrations only, are required to pay Three Guineas before the first day of December.

(d). Students of more than three years' standing in the Dissecting Room of Trinity College are privileged to use the Dissecting Room, on payment of the sum of One Guinea on entrance.

(e) The Student accompanying the Professor of Botany on the Botanical Excursion is required to have with him a copy of the London Catalogue of Plants, price 6d.; and either Babington's or Hooker's British Flora.

16. That Two Years' attendance in Arts be required as a qualification for the Medical and Surgical Licences, in addition to the Medical and Surgical Courses.

17. That Candidates for the Degree of Bachelor in Medicine shall be, in future, required to produce a Certificate of actual attendance upon cases of Fever.

THE QUEEN'S UNIVERSITY IN IRELAND.

FACULTY OF MEDICINE.

DEGREE OF DOCTOR OF MEDICINE.

EACH candidate for the degree is required—

1. To have passed in one of the Queen's Colleges the examination for Matriculation in Arts (a), and to have been Matriculated in Medicine.
2. To have attended in one of the Queen's Colleges, Lectures on one Continental language for six months, and on Natural Philosophy for six months.
3. To have attended, in some one of the Queen's Colleges, two other courses of the Medical curriculum. For the remainder of the courses, certificates will be received from the Lecturers in Schools, recognised by the Senate.
4. To pass two University Examinations—The First University Examination and the Degree Examination.

The curriculum of Medical study extends over four years, and is divided into two periods of two years each.

The first period comprises attendance on Chemistry, Natural History, Anatomy and Physiology, Practical Anatomy, and *Materia Medica*. Practical Chemistry in a recognised Laboratory is also to be attended during the first period, and the practice during six months of a Medico-Chirurgical Hospital, containing at least sixty beds, together with the Clinical Lectures delivered therein.

The second period comprises attendance on Anatomy and Physiology, Practical Anatomy, Theory and Practice of Surgery, Midwifery and Diseases of Women and Children, Theory and Practice of Medicine, Medical Jurisprudence. During this period Students attend Practical Midwifery, and eighteen months' practice of a Medico-Chirurgical Hospital, containing at least sixty beds, and in which clinical instruction is delivered.

At least two of the above courses of Lectures must be attended in some one of the Queen's Colleges; the remainder may be taken at the option of the candidate, in any University, College, or School recognised by the Senate of the Queen's University.

The University Examinations are held twice in each year, in June and September.

Each candidate for examination in June must forward to the Secretary, before the 1st of June, notice of his intention to offer himself, along with his certificates; and each candidate for examination in September or October must forward similar notice, along with his certificates, before the 1st of September.

THE FIRST UNIVERSITY EXAMINATION IN MEDICINE.

The First Examination may be passed either in June or September.

Students may present themselves for this Examination at the termination of the first period of the Curriculum, or at any subsequent period.

Before being examined, each candidate must produce evidence of having completed the course recommended for study during the first period.

HONOURS.

Competitors for Honours will be examined in all the subjects of the First Medical Examination, including Experimental Physics and Modern Languages.

DEGREE EXAMINATION IN MEDICINE.

Examinations for the M.D. will be held in June and September. The fee is £5.

Each candidate must produce—

1. A certificate from the Secretary of the Queen's University, that he has passed the previous examination, unless he presents himself for both examinations simultaneously.
2. From the Council of his College that he has passed a

(a) The following are the subjects of Examination. Homer's *Iliad*, Books I, II (omitting Catalogue of Ships), III; Lucian's *Dialogues* (Walker's edition); Xenophon's *Anabasis*, Books I, II, III; Virgil, *Æneid*, Books I, II, III; Sallust; Horace, *Satires*; Latin Prose Composition; English Prose Composition; English History; Modern Geography; Arithmetic; Algebra, to the end of Simple Equations; Euclid, Books I, II, III.

full examination for Matriculation in Arts, and has been admitted a Matriculated Student in the Faculty of Medicine.

3. That he has attended in the College lectures on one Modern Language, on Experimental Physics, and two other courses.

4. That he has completed all other prescribed courses.

The Degree Examination comprises the subjects recommended for study during the second period, along with Experimental Physics and one Modern Language, unless an Examination in these subjects has been already passed at the previous Medical Examination.

The examination for the Degree of M.Ch. comprises in addition an examination in Operative Surgery.

See advertisements of Queen's Colleges, Belfast, and Cork.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

The Council of the Royal College of Surgeons adopted last year a new scheme of examination to supersede the existing scheme. The new method of examination is framed with the object of enabling the student to pass through his examinations *gradatim*, instead of being obliged to encounter the ordeal of the whole examination at one time. Thus, the divided examinations will be at once easier for the student, and a much more rational and perfect test than the old system.

The old system is, however, continued for the present, to enable students who have already commenced their curriculum to complete it as had been originally intended. All students joining the Profession, or who have passed their first examination, should proceed upon the new system, as it will be easier and much more instructive.

REGISTRATION OF PUPILS.

Every person, and without any examination, shall be registered as a pupil on payment of five guineas, which is allowed in his diploma fee.

Registered pupils can study in the museum on two days in each week, and read in the library every day from ten till one. They may also attend the Lectures on Comparative Anatomy, and obtain the certificate without payment. No student is admitted to the sessional or final examination for letters testimonial until he becomes a registered pupil, but he may register at any time previous.

CLASSICAL EXAMINATION.

Students are admitted to this examination at any period previous to the final examination for letters testimonial.

The following are the subjects for the Preliminary Examination:—The English Language, including Grammar and Composition. Arithmetic, including Vulgar and Decimal Fractions. Algebra, including Simple Equations. Geometry, first two books of Euclid. Latin and Greek, including Translation and Grammar. In Greek—The Gospel of St. John, the Menippus of Lucian, or the First Book of Xenophon's *Anabasis*. In Latin—The First and Second Books of the *Aeneid* of Virgil, the Jugurthine War of Sallust, or the Third Book of Livy. These examinations are held quarterly, viz.:—On the third Wednesday in January, April, July, and October, in each year. Fee, ten shillings.

DIPLOMA IN MIDWIFERY.

Any Fellow or Licentiate shall be admitted to an examination upon the following documents:—

a. Certificates of one course of lectures on Midwifery and Diseases of Women and Children.

b. That he has attended a recognised lying-in hospital for six months; or a recognised dispensary for lying-in women and children, devoted to this branch of surgery alone.

c. That he has conducted thirty labour cases. Candidates for the Midwifery Diploma shall be examined on the organisation of the female; the growth and peculiarities of the fœtus; the practice of midwifery, and the diseases of women and children.

Licentiates of a college of physicians or graduates in medicine of a University, shall be examined in general and Descriptive Anatomy, Physiology, the Theory and Practice of Surgery, and Operative Surgery. Rejected candidates cannot present themselves until after six months.

The conduct of the examinations under the old scheme is the same as herein described, except that the examinations

are two instead of three, and are held on the fourth Tuesday in January, April, July, and October.

CURRICULA.

The Junior Class shall produce certificates of three courses of Lectures on Anatomy and Physiology, three courses on Practical Anatomy, with dissections; two courses on Chemistry, one course on *Materia Medica*, one course on Botany, and one course on Forensic Medicine.

This class shall be examined in Anatomy, Physiology, and *Materia Medica*.

The Senior Class shall produce certificates of three courses on the Theory and Practice of Surgery, one course on the Practice of Medicine, and one course on Midwifery; also of attendance at a recognised hospital for three Winter and three Summer Sessions.

This class shall be examined in Surgery, Operative Surgery, the Practice of Medicine, and form of Prescription.

The examinations in Operative Surgery are conducted by the four surgical examiners. The questions are written upon cards deposited in a balloting-box, from which each candidate, as called up, draws his question, and performs the operations there indicated.

Any candidate rejected in Operative Surgery is not permitted to present himself for the senior *viva voce* examination.

The fee for this examination shall be fifteen guineas.

FEES TO BE PAID BY CANDIDATES FOR LETTERS TESTIMONIAL ON THE OLD SYSTEM.

1st. The candidate pays ten shillings for his preliminary examination.

2nd. Five guineas as registered pupil of the College.

3rd. Five guineas for the Junior Class examination, which is not returned in case of rejection, but is allowed in the fee for his second examination.

4th. Fifteen guineas for the Senior Class examination—total, £26 15s.

5th. Every candidate rejected at the quarterly examinations shall be required to pay to the College the sum of two guineas on applying for re-examination.

6th. The Registrar receives £1 1s. on handing over the diploma.

The Sessional Examinations essential for the granting of the Letters Testimonial are to be three in number, instead of two, as at present, and must be passed by the candidate within the following periods:—

- The Primary Examination, at any examination after the termination of the Second Summer Session.
- The Secondary, at any examination after the termination of the Third Summer Session.
- The Pass or Practical Examination, at any examination after the termination of the Fourth Summer Session.

Each examination will occupy two days, of which the first is to be devoted, in the Primary and Secondary Examinations, to the writing of answers to printed questions; and in the Pass Examination, to clinical examination and operative surgery; and in the second day, in all cases, to *viva voce*.

For the written examination four hours are to be allowed to candidates on the first day,—two in the forenoon and two in the afternoon; but candidates may retire from the hall when they shall have completed their answers, and handed their papers to the Examiner.

The *Viva Voce* Examinations commence on the day following the written examinations, and are continued from day to day until all candidates have been examined. Each candidate is examined for a quarter of an hour by each of the four examiners.

The Sessional Examinations commence on the second Tuesday in April and July, and the first Tuesday in December. The Primary and Secondary written examinations take place on the first day; and the *Viva Voce* Examination first of the Primary and afterwards of the Secondary class, are continued from day to day in the alphabetical order of candidates' names.

The candidates are to assemble in one of the rooms of the College, having been previously informed of the hour at which they are to attend by means of a note forwarded to their addresses through the post, and at the conclusion

of the examination the result is communicated to them in the same manner.

For the Primary Examination: The subjects for this examination are—

- a. Anatomy (bones, muscles, ligaments, chest, abdomen, urinary and genital organs).
- b. Physiology of digestion and of absorption.
- c. Chemistry (chemistry and physics, as applied to pharmacy and medicine).
- d. *Materia Medica* and Medical Botany (not including prescriptions or pharmacy).
- e. Principles of Surgery (inflammation and its consequences).

For this examination the candidate is required to produce the following certificates:—

(a) Practical Anatomy, with demonstrations and dissections, two winter sessions; (b) Physiology, one course; (c) Theoretical Chemistry, one course; (d) Practical Chemistry, one course; (e) *Materia Medica*, one course; (f) Botany, one course; (g) Surgery, one course; (h) Eighteen months' hospital attendance.

Secondary Examination: The subjects for this examination are—

- a. Anatomy (regional and surgical).
- b. Physiology and Histology.
- c. Surgery (general and theoretical).
- d. Medicine (practical).

The description of anatomical specimens, and of microscopic histological preparations form part of the written examination.

Also the candidate is required to produce the following certificates, in addition to those required for the Primary Examination:—

(a) Physiology, two courses; (b) Practical Anatomy, one course; (c) Surgery, one course; (d) Practice of Medicine, one course; (e) Medical Jurisprudence, one course; (f) Nine months' hospital attendance.

Final or Pass Examination: The subjects of this examination are—

- a. Clinical Examination.
- b. Surgical Operations.
- c. Surgical Appliances.
- d. Prescriptions.
- e. Medical Jurisprudence.

Clinical Examinations.

The forenoon of the first day of the Pass Examination is devoted to Clinical Examination, and the afternoon to Operative Surgery.

The candidates attend at the College half an hour before the time fixed for the Clinical Examination, and a certain number of candidates, previously selected by lot to attend each hospital, are then informed as to the hospital at which they are to be examined, and proceed thither at once to meet their examiner.

On the afternoon of the same day the examinations in Operative Surgery and Surgical Appliances take place, and that not less than two operations and three surgical appliances form the subjects of examination for each candidate.

The second day of the Pass Examinations is devoted to the writing of prescriptions and to Medical jurisprudence; and each candidate is examined for one hour.

Midwifery Examination.

An examination in Midwifery is held at the same time as the Pass Examination; the passing of which shall, however, not be compulsory on candidates for Letters Testimonial. Any candidate presenting himself for examination in that subject shall, if passed, receive the Midwifery Diploma without extra fee.

The candidate is required to produce the following certificates, in addition to those required for his two previous examinations:—(a) Midwifery, one course; (b) Surgery, one course.

Marks to be Given.

The maximum number of marks which it shall be possible for any candidate to receive at any examination shall be fixed at 40; he shall not be allowed to pass unless his aggregate marks amount to 25; that no examiner shall give a higher number than 10.

Fees to be paid by the Candidate in respect of each Examination.

1. That each registered pupil shall be admitted to the Primary Examinations on payment of a fee of £5 5s.

2. That the fees for the Second and Final Examination shall be £5 5s. each, and that a fee of £5 5s. shall be paid, in addition, previous to the Final Examination for the Diploma.

3. Any rejected candidate seeking re-examination shall pay an additional fee for such examination of £2 2s.

4. That no fee shall be charged for the Midwifery Diploma to any candidate who may pass in Midwifery at his Final Examination, or the next following periodical examination.

We are informed, and received the information with much regret, that the Council have decided to leave this much needed reform of the admittedly defective examination system to the option of the student. Examinations under the old system will still be continued, and the improved and more liberal method will not be obligatory upon any student, except those who commence their studies henceforth. This compromise is so obviously impracticable and undesirable that we are assured it must fall to the ground in a few months, and the reformed examination be substituted in all cases for the present inefficient test.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

REGULATIONS RELATIVE TO THE LICENCE IN MEDICINE.

EXAMINATIONS are held on the second Tuesday in each month.

The name of every candidate, together with his Schedule and the required documents, must first be submitted to the College on the first Friday in each month, and no name can be received later than the Monday previous.

REGULATIONS RESPECTING THE LICENCES IN MEDICINE AND MIDWIFERY.

Candidates who have not obtained some Medical or surgical qualification must give proof of four years' study; and of having studied Anatomy and Physiology, Practical Anatomy, Chemistry, Practical Chemistry, *Materia Medica*, Botany, Medical Jurisprudence, Practice of Medicine, and Pathology, Surgery, Midwifery.

Of having attended a Medico-Chirurgical Hospital, with Clinical Lectures, for twenty-seven months.

Of six months' Practical Midwifery at a hospital, or other evidence of having attended Practical Midwifery.

Testimonials of character from two registered Physicians or Surgeons.

A Candidate who has already obtained a Medical or Surgical Qualification is required to fill up a Schedule; but he is only required to produce his Diploma or Certificate of Registration, and the Certificate of Practical Midwifery, and Testimonials as to character.

The examination is partly by written questions, partly *Viva Voce*, and partly Clinical, and divided into two parts:

First Part.—Anatomy, Physiology, Botany, and Chemistry.

Second Part.—*Materia Medica*, Practice of Medicine, Medical Jurisprudence and Midwifery.

Candidates qualified as follows are required to undergo the second part only—viz., 1. Graduates in Medicine of a University. 2. Fellows, Members, or Licentiate, of the Colleges of Physicians of London or Edinburgh, admitted upon examination. 3. Graduates or Licentiate in Surgery. 4. Candidates who, having completed the curriculum, shall have passed the previous examination of any of the Licensing Corporations in the United Kingdom.

Under this last regulation gentlemen who have passed the first portion of the examination for the Licence of the Royal College of Surgeons of Ireland or the Royal College of Surgeons of England are exempted from the first part of the examination.

Candidates who have been five years in practice are not required to undergo the written or clinical portion of the examination.

REGULATIONS RELATIVE TO THE DIPLOMA IN MIDWIFERY.

Examinations for the Diploma in Midwifery are held on the day after those for the Licence in Medicine.

Candidates not being Licentiate will be admitted on the following qualifications:—The Degree or Licence in Medi-

cine or Surgery, with a Certificate of six months' Lectures on Midwifery, with six months at a recognised lying-in Hospital, or of having attended Practical Midwifery for six months at a recognised lying-in Hospital, or other evidence of having attended Practical Midwifery.

FEES FOR LICENCE AND EXAMINATIONS.

The Fee for the Licence is £15 15s.

The Fee for the Midwifery Diploma is £3 3s.

The Fee for the Licence in Medicine and Diploma in Midwifery, if taken out within one month, £16.

Further information and blank schedules may be obtained by application personally, or by letter, to the Registrar, College of Physicians, Kildare Street, Dublin.

THE APOTHECARIES' HALL OF IRELAND.

THE ARTS' EXAMINATIONS

Will be held at the Hall four times in the year, viz., the *third* Thursday in the months of January, April, July, and October, at the hour of Twelve o'clock, noon. It will be conducted by means of printed Papers and *viva voce* by Special Examiners (Graduates in Arts of the University of Dublin), under the supervision of the Court of Directors; the Answers to the Papers will be required in Writing.

THE PROFESSIONAL EDUCATION AND EXAMINATIONS.

Every Candidate for the *Licence to practise* must produce Certificates—

1. Of having passed an Examination in Arts previously to professional study.
2. Of being at least twenty-one years of age, and of good moral character.
3. Of Apprenticeship to a qualified Apothecary, or *practical* Pharmacy with an Apothecary for *three* years subsequent to the Examination in Arts.
4. Of *four* years Professional Study.
5. Of having attended the following Courses, viz. :—
Chemistry, one Winter; Anatomy and Physiology, two Winters; Demonstrations and Dissections, two Winters; Botany and Natural History, one Summer; Practical Chemistry, three Months; *Materia Medica*, three Months; Principles and Practice of Medicine, one Winter; Midwifery and Diseases of Women and Children, six Months; Practical Midwifery (attendance upon twenty cases); Surgery, one Winter; Forensic Medicine, one Summer; Instruction in Vaccination.
6. Of having attended a recognised Hospital, during two Winters and two Summers.
7. Of having performed the operation of Vaccination successfully under a recognised Vaccinator.

The Examination for the *Licence* is divided into two parts :
The **FIRST PART** comprehends Chemistry, Botany, Anatomy, Physiology, and Pharmacy.

The **SECOND**—Medicine, Surgery, Pathology, Therapeutics, Midwifery, Forensic Medicine, and Hygiene.

THE PROFESSIONAL EXAMINATIONS

Will be held *quarterly* on the first and second Monday in January, April, July, and October.

The **FIRST PART**, for Junior Students, on the *first* Monday at Twelve o'clock, noon; and on the Tuesday and Wednesday succeeding at the same hour.

Subjects :—Chemistry and Botany, *Monday*; Anatomy and Physiology, *Tuesday*; Pharmacy, *Wednesday*.

The **SECOND PART**, or Pass Examination for Senior Students, on the *second* Monday, at Twelve o'clock, noon; and on the Tuesday and Wednesday succeeding, at the same hour.

On Thursday, Clinical Examination.

Subjects :—Medicine and Surgery, *Monday*; Midwifery and Diseases of Women and Children, *Tuesday*; Forensic Medicine and Hygiene, *Wednesday*; Clinical Examination, *Thursday*.

The first two hours of each day will be devoted to writing Answers, and after that, two hours to an oral and practical Examination.

Doctors of Medicine, and Licentiate of a College of Physicians or Surgeons, who have served an Apprenticeship, or the required term at *practical* Pharmacy, may obtain the Licence by undergoing an Examination—the former in Pharmacy, and the latter in Medicine and Pharmacy. Licentiates of the London Society of Apothecaries are admitted *ad eundem*.

An *Honor* Examination for Apprentices is held in the first week in May, upon some subject of Medical or Pharmaceutical Chemistry, and a Prize of Five Guineas is awarded to the successful Competitor.

MEDICAL SCHOOLS AND HOSPITALS.

THE Clinical Hospitals of Dublin are 10 in number, exclusive of the Cork Street Fever Hospital, the Children's Hospital in Pitt Street, the Dublin Eye and Ear Infirmary in Ely Place, and other special institutions. To some of these institutions Medical Schools are attached, others, though they have no actual or official connection with any school, are in close affinity with certain teaching bodies, while others again are without any special connection with any school. While, however, such affiliation of a school and hospital may exist, it should be remembered that the Dublin schools and hospitals are open to all comers, and the Student is competent to attend any hospital and any school he wishes. The restriction which rendered it obligatory for Candidates for the Medical Degrees of the University of Dublin to attend Sir Patrick Dun's Hospital, was recently abolished, and perfect "free trade" thus established.

THE SCHOOL OF PHYSIC T.C.D., AND SIR PATRICK DUN'S HOSPITAL.—The Medical School is at Trinity College. All Candidates for the Medical Degrees of the University must attend a certain proportion of their curriculum in it.

THE ROYAL COLLEGE OF SURGEONS SCHOOL is situated within the walls of the College, and is under the superintendence of the Council, who appoint the professors. The Introductory Address is given on the first Monday in November, and immediately afterwards the Professor of Physiology commences his course with a series of twelve lectures on Comparative Anatomy—free to the public. The dissecting-rooms have been recently much enlarged. Prizes in Anatomy and Physiology, and Surgery, will be awarded at the end of the Winter Session.

THE CITY OF DUBLIN HOSPITAL has been hitherto more closely connected with the College School than any other hospital. It is situated in Upper Baggot Street, about ten minutes' walk from the Royal College of Surgeons. The hospital contains 104 beds, and accommodates about 800 intern patients annually. There are special wards for ophthalmic and aural diseases (on which subjects a special course of lectures is delivered), and for diseases of children. A new wing has been lately opened for the reception of fever and other infectious diseases. The "Purser" Studentship of £20 per annum (with apartments) is obtainable by competitive examination by all students; numerous prizes and medals are given, and special certificates are granted.

THE CATHOLIC UNIVERSITY SCHOOL is situated in Cecilia Street, about ten minutes' walk from the University itself in St. Stephen's Green.

The Hospitals most closely connected with this School are St. Vincent's, in St. Stephen's Green; the Mater Misericordiarum Hospital, in Eccles Street; Jervis Street Hospital; and House of Industry Hospital.

ST. VINCENT'S HOSPITAL was established in 1834 by the Sisters of Charity, some of whom had studied the system of the Parisian hospitals, after which it was modelled. The ward for "*Enfants Malades*" is an interesting feature. The hospital has over a hundred beds constantly full, and each sister has charge of about twelve patients. In connection with it a Convalescent Home was established four years since at Stillorgan. The clinical instruction in medicine and surgery is given by Dr. Quinlan, Dr. Mapother, Dr. O'Leary, and Dr. Cryan. Senior and Junior Prizes in clinical medicine or surgery are awarded at the end of the Winter Session.

A respectable lodging-house in Lower Leeson Street (within a minute's walk of the hospital) provides lodgings for students, at from 5s. per week and upwards. Maintenance varies, according to the habits of the student, from 15s. to 25s. per week.

The Introductory Lecture will be delivered by Dr. Cryan on Monday, November 4th, 10.30 a.m.

THE MATER MISERICORDIARUM HOSPITAL is the largest of the Dublin hospitals, and is intended to be much extended. It is situated at the northern side of the town.

There are three resident pupils appointed every six months. Good lodgings can be had very cheap close to the hospital. Prizes to the value of £30 are awarded at the end of the Winter Session, for the best reports on the cases under treatment in the hospital. The Introductory Lecture will be delivered by Dr. Coppinger,

JERVIS STREET HOSPITAL is one of the oldest established charitable institutions in Dublin, having been founded in 1721. It is situated in the neighbourhood of the Carmichael and Catholic University Schools, and in a part of the city not otherwise provided with hospital relief, and which, from its dense and poor population, and from the many factories, &c., in its vicinity, supplies at all times valuable and unique Medical and surgical cases. The hospital being found inadequate to the demands upon it, is about to be rebuilt. There will be no Introductory Lecture.

The **LEDWICH SCHOOL** was founded in 1810 by the well-known Dr. Kirby, and since then has fully sustained its prestige under the management of the Messrs. Ledwich and Mason, after the former of whom it is named. It is situated in Peter Street, not five minutes' walk from the College of Surgeons, the Meath, and Mercer's Hospitals, and in the same street with the Adelaide Hospital and the Anglesse branch of the Coombe Lying-in-Hospital, and ten minutes' from the Catholic University School, the School of Physic, and the City of Dublin Hospital.

MERCER'S HOSPITAL was founded on the bequest of Mrs. Mary Mercer. It is one of the oldest hospitals in Dublin, and receives a great number of accident cases. It is situated in Stephen's Street, close to the College of Surgeons, Ledwich School, and Adelaide Hospital.

The **CARMICHAEL SCHOOL** is situated in North Brunswick Street.

The various lectures are now delivered, and the dissections carried on in the new building, which the munificence of the late Surgeon Carmichael has given to the proprietors. As the building was designed with special reference to the requirements of a large Medical class, every convenience is afforded to the student in the prosecution of his studies.

The connection of this School with the Richmond, Whitworth, and Hardwicke, Meath and Jervis Street Hospitals, through its teachers, ensures equal opportunities to the pupils of becoming thoroughly acquainted with the more immediately practical part of their profession.

Arrangements have now been completed for rendering more available the Carmichael premium bequest, which enable the proprietors to distribute prizes to the amount of £80 yearly; and the Scholarship, value £15 yearly, which the friends of the late Dr. Mayne founded in his name, is allotted at the termination of the Winter Session.

To fill the vacancies which have recently occurred, the following appointments have been made:—

1. Joint Lecturer on Anatomy and Physiology—Reuben J. Harvey, M.B., Ch.M., T.C.D., late Demonstrator of Anatomy, School of Medicine, Trinity College, Dublin.

2. Joint Lecturer on Descriptive, Practical, and Surgical Anatomy—Gerald F. Yeo, M.D., Ch.M. T.C.D., L.R.C.S.I., Assistant Physician to the Richmond, Whitworth, and Hardwicke Hospitals.

Dr. Harvey is already known as a teacher, and his original investigations on the Development of Endothelial Cells, which were fortunate enough to secure the approbation of Stricker, were published in the "Medizinische Jahrbücher" for 1871. Dr. Yeo's paper containing his researches "On the Structure of Inflamed Lymphatic Glands" had the honour of appearing in the same periodical. Dr. Yeo's name also appears on the distinguished roll of Pathological Gold Medallists.

DR. STEVEN'S HOSPITAL AND SCHOOL are situated close to the Kingsbridge Terminus of the Great Southern and Western Railway, and therefore occupy a position of their own, far removed from the other Medical institutions.

Immediately adjoining is St. Patrick's (Swift's) Asylum for the Insane.

There is accommodation for residence of seven surgical and four Medical residents; besides whom the Resident-Surgeon receives house pupils. The fees payable for the privilege of residence are 21 guineas, winter; 15 guineas, summer six months; including hospital ticket; students have apartments, coal, gas, and furniture.

Accommodation outside the hospital, in the neighbourhood, is arranged by the hospital authorities.

PRIZES.

Three Cusack Medical and Exhibition, of £8, £5, £3; two Midwifery Assistants, £30 each; one Medical Clinical Prize, £10 10s.; one Surgical Prize, £10 10s.

The session opens with the distribution of prizes in the first week in November.

As we have said, certain hospitals have no special affinity

with any College or School, Of these are the Meath and Adelaide Hospitals.

THE MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.—This hospital is situated about a quarter of an hour's walk from the University, and within a few minutes of the College of Surgeons and the Ledwich Schools of Medicine; affords every facility for the treatment and study of disease. Its salubrious position and long-established character call for constant admission to its accident, chronic, fever, surgical, and children's wards, which are thus constantly occupied with cases illustrative of medicine and surgery.

Four prizes will be given at the termination of the Winter Course to the best answerers in their respective classes.

The **ADELAIDE HOSPITAL** is in Peter Street, next door to the Ledwich School, and within a few minutes' walk of the College of Surgeons and the Universities. From the 1st of October the physicians and surgeons will visit the wards, and give instructions at the bedside, at the advertised hours, and the course of clinical lectures will be commenced in the beginning of November.

There are fever wards apart from the hospital, and two wards for infants and children. Special hours are devoted to clinical instruction in the Diseases peculiar to Women, the Diseases of the Eye, and Cutaneous Diseases, and Students are individually instructed in the use of the Stethoscope, Ophthalmoscope, Laryngoscope, and Microscope. Two resident pupils are selected half-yearly. Prize examinations are held at the termination of the Session.

SPECIAL HOSPITALS.

The Special Hospitals of Dublin are the Westmoreland Lock Hospital, Cork Street Fever Hospital, Pitt Street Children's Infirmary, the Dublin Eye and Ear Infirmary, St. Mark's Ophthalmic Hospital, and the National Eye and Ear Infirmary.

The **LOCK HOSPITAL** is supported by Government for the treatment of venereal diseases, and as such is one of the most valuable special hospitals in Dublin. Mr. McDowell and Professor Morgan are its surgeons, and especially for military surgeons the practice of the hospital is very valuable.

The **PITT STREET CHILDREN'S INFIRMARY** is situated close to Mercer's Hospital and the College of Surgeons. It was founded to provide treatment specially for children, and to teach that special branch of disease. Dr. Moore and Dr. Churchill, senior, are the Medical Officers.

The **DUBLIN INFIRMARY FOR DISEASES OF THE EYE AND EAR** was founded in the course of this year. It accommodates eighteen beds, and has for its chief surgeon Dr. Jacob, formerly Ophthalmic and Aural Surgeon to the City of Dublin Hospital; and for its consultants, Mr. Porter, Surgeon to the Queen in Ireland, Dr. Evory Kennedy, and Dr. John Cronyn. At the Dispensary every form of disease of the eye or ear is seen thrice weekly, and operations are performed on Tuesdays and Thursdays at four o'clock. Particulars of fees for attendance may be had from Dr. Jacob.

ST. MARK'S OPHTHALMIC HOSPITAL AND DISPENSARY FOR DISEASES OF THE EYE AND EAR.—Attending Surgeons: Sir William Wilde, M.D., F.R.C.S., Surgeon-Oculist in Ireland to Her Majesty; Henry Wilson, F.R.C.S., Professor of Ophthalmic and Aural Surgery, R.C.S., Examiner in the University of Dublin. Instruction is given on the mornings of Tuesdays and Fridays from eleven to one o'clock, and operations performed on Wednesdays from eleven to one o'clock. Fee: for three months' attendance, £3 8s.

LYING-IN HOSPITALS.

ROTUNDA HOSPITAL.—This well-known institution is the largest and oldest maternity hospital in the United Kingdom, and the repute in which it is held attracts students from all parts of the world. It accommodates an average of 1,700 intern patients, including those admitted to the chronic wards labouring under the various forms of uterine complaints, and is under the care of the Master, who is elected every seven years, and two assistants, who hold these appointments for three years. The mastership is at present held by Dr. Johnston, and the assistant is Dr. Alexander Taylor. There is, in addition, an external maternity department, where patients, procuring a ticket properly signed, can be attended at their homes; also, a dispensary is held every morning for diseases of women and children. Clinical instruction is given each morning both in the labour as well as in the chronic wards, and two courses of lectures are delivered in the year, which are recognised by all the licensing bodies.

A student entering for the practice of the hospital pays a fee of £10 10s. for six months. During that time he is required to attend at least thirty cases, either within the walls of the hospital or at the residence of patients who may apply for assistance. For this course of study, on examination, a diploma is given, which is received as a qualification in midwifery in the public services.

A limited number of students are admitted to reside in the hospital, for which they pay a fee of twenty guineas for six months.

COOMBE HOSPITAL.—This hospital was founded in 1826, but it was not till 1867 that it was incorporated by Royal Charter, which enables its Medical officers to issue diplomas qualifying the holders to practise midwifery. By a clause in the Charter the diplomas issued antecedent to its date have been made with equal force and value with those issued subsequent thereto. This hospital divides with the Rotunda almost the entire of the obstetric hospital practice of Dublin. It is situated in the centre of a district densely populated by the lower orders, and thus affords the amplest opportunities for practice. It accommodates about 600 labour cases within its walls, while those attended as externs amount to nearly double that number. Moreover, the chronic ward for the reception of cases of the diseases of females gives admission to about eighty patients annually. Its wards are in the charge of Dr. Ringland and Dr. Sawyer, as masters, and Dr. A. H. Ringland as assistant master, whilst the chronic ward for the diseases of females is under the charge of Dr. Kidd, the obstetric surgeon of the institution. The fee for attendance is £4 4s. for six months as extern, and £10 10s. as intern pupil. During that period the student attends on a given night in each week, or oftener, if circumstances permit, and takes charge in his turn of any cases that may be admitted to the labour wards, or may call for his assistance outside. In difficult cases he has the superintendence of the resident Medical officer, and of the masters when necessary. An annual examination is held in May and November, at which prizes of considerable amount are awarded, and certificates of good answering granted. Two paid resident pupil midwifery assistantships are obtainable annually by competitive examination, for which all pupils who have obtained their midwifery diploma are eligible.

IRISH PROVINCIAL SCHOOLS.

QUEEN'S COLLEGE, BELFAST.

The first Matriculation Examination will commence on October 17. There will be an additional Matriculation Examination on the 12th November for those who have not been able to present themselves at the first. Lectures will commence on October 29. No student can be permitted to enter after the 12th of November. Two junior scholarships, value £25 each, are awarded to matriculated students commencing the first year of their study. The examination for these will take place immediately after the first Matriculation Examination. Two of similar value to students of the second year, two to students of the third year, and two to students of the fourth year.

For the subjects of examination and other information see Queen's College Calendar for 1872. At the termination of the Session, prizes will be awarded for proficiency in the several classes.

The Trustees of the "Charters' Educational Fund," grant annually a sum of £50 for an exhibition in connection with the Belfast School of Medicine. The competitive examination for this exhibition will be held at the end of the Session, at which all Medical students can compete.

FEES.—Practical chemistry, £3. Anatomy and physiology, first course, £3; subsequent course, £2. Anatomical demonstrations and practical anatomy, each course, £3. For subjects each Session, 15s. Other Medical lectures, first course, £2; each subsequent course, £1.

A detail of the prizes and exhibitions in arts and medicine, the names of the Professors, and other information, will be found in the advertisement of this issue, and full details may be had on application to the Rev. Richard Oulton, B.D., Registrar.

QUEEN'S COLLEGE, GALWAY.

The College Session is divided into three terms. The first term commences in October.

Matriculation.

The Matriculation Examination is held at the commencement of the first term; but additional examinations are held before the close of the term. The last Matriculation Examination is held on the 16th November. Each candidate before being admitted to examination must pay a fee of ten shillings, which will be returned to such as fail to pass.

Attendance on Lectures.

All students shall pay the College fee, and a moiety of their class fees, and enter their names with the Registrar, before they are admitted to the classes of the several Professors. No student shall have his name replaced on the rolls at the second term who has not paid the second moiety of his class fees. No student shall be regarded as having kept a course of lectures who has not attended two-thirds of the entire number.

Examination.

A Sessional Examination is held at the close of each Session in the subjects of lectures. There is also a Supplementary Examination on the same subjects at the commencement of the following session.

Scholarships.

Eight Junior Scholarships, of the value of £25 each, are awarded to students pursuing the course for the degree of M.D. The examinations for junior scholarships are held at the commencement of the first term. Junior scholars are exempted from one moiety of the class fees. The College is empowered to award exhibitions, varying in value from £12 to £18, at the same examinations as the scholarships, and to be held upon the same terms.

THE ROYAL COLLEGE OF SCIENCE, established at the Museum of Irish Industry, in St. Stephen's Green, is a branch of the Science and Art Department at South Kensington. A complete Staff of Professors is connected with the institution, and courses of lectures are delivered on all Scientific Departments to which the admission charge is moderate.

RELATIVE COST OF MEDICAL EDUCATION IN IRELAND.

UNIVERSITY OF DUBLIN, M.B. AND M.Ch.		£	s.	d.
I. Lectures	49	12	0
II. Hospitals	33	12	0
III. Degrees	32	0	0
		115	4	0
Expense of Degree in Arts	83	4	0
Total	£198	8	0

QUEEN'S UNIVERSITY M.D. AND M.Ch.
If two years' Lectures and Hospital be taken in Dublin, about £67 0 0

COLLEGES OF SURGEONS AND PHYSICIANS.
About £140 0 0

On these terms a reduction may be made by cash payments to Hospital and College at the commencement of study.

INTRODUCTORIES IN DUBLIN.

The dates of the Introductories in Dublin and the Lecturers who are to deliver them have not yet in the majority of instances been fixed.

At the Royal College of Surgeons Dr. Davy, the Professor of Botany in the College, will open the Session on the first Monday in November.

Dr. Coppinger will deliver the Introductory at the Mater Misericordie Hospital, and Dr. Cryan at St. Vincent's.

At the Carmichael School and Jervis Street Hospital there will be no Introductories, and at Steven's the Session is always inaugurated by the annual distribution of prizes.

DISEASES OF WOMEN.

By CHAS. R. DRYSDALE, M.D., M.R.C.P.L., F.R.C.S.E., Physician to the Metropolitan Free Hospital, London, and to the North London Hospital for Consumption and Diseases of the Chest.

THANKS to the unwearied labours of a class of practitioners who have devoted their time to a great extent solely to the mechanism of labour, and to the diseases of the uterus, we have now arrived at the possession of a large amount of sound doctrine in this department of practical medicine. This expression must not be held to indicate that the author supposes that most of the difficult points in female diseases are made out. Far from it. The genius of Simpson, of Henry Bennett, and many others, has only perhaps shown more clearly how difficult it is not to exaggerate any point in the science of medicine, and the way in which the diseases of women have passed through the operative era of Dr. Marion Sims, and other enthusiastic surgeons, shows that a good deal has still to be done before we have a correct notion of Nature in all her simplicity. It is by no means necessary to enter into much detail upon practical matters in this place, so that it may be as well to describe at once the aids to exploration of the female generative organs which have seemed most useful in the author's opinion.

It will be as well to say a word as to the position which the patient who is examined should assume. When we are practising *the touch*, it is much better to let the patient lie on the back, with the thighs flexed on the abdomen, and perhaps to use the *left* forefinger for introduction into the vagina, whilst we use the right hand to ascertain the existence of any abdominal tumour, or displacement of the pelvic viscera. In some cases doubtless also great information may be elicited by using the touch, when the patient is standing up and resting against the wall. The phenomenon of ballottement of the gravid uterus is made clear in this manner, and flexions and prolapse of the uterus are often better made out by this process. The

uterine sound is greatly used now-a-days, and the author has much to say in its favour. It was introduced into the Profession by Simpson in the year 1843. The instrument, of course, must never be used where there is the faintest possibility of pregnancy being present; and, in all cases, the greatest gentleness is required in passing it. If it does not pass at all easily, the end should be bent in different curves, until it enters the uterus without any force. Simpson's sound, and, perhaps, Sims', are all that are necessary for the practitioner to possess. The author does not remember ever, in his own practice, to have done any great damage with this instrument; but, in one case, there was considerable flooding after the use of the sound. Many writers, however, say that the use of the sound has done much more harm than good, and certainly we should therefore use the instrument as rarely as we can.

The days are gone by for Medical paper wars, as to the utility of the uterine speculum—and it is, therefore, only requisite for us to indicate the way in which this important instrument is best used, and the varieties of make most useful in practice. Récauier, in 1821, was the first to use the vaginal speculum for the ordinary examination of women with uterine disease. The author believes that the most useful instruments now made are the bivalve speculum of Cusco or Tyler Smith, and pewter speculums, of various calibre, used in Paris. Glass speculums are always breaking, and are by no means free from liability to do so when in the vagina. Coxeter's speculum, though useful, is not so good as Cusco's. When the light is sufficient, and patients timid, the speculum examination in this country should be made whilst the patient lies on the left side. When the light is bad, however, the uterus will certainly often be much better inspected if the patient lies in the supine position. Sometimes a very long speculum (seven inches) is required; but not often. The author has found Mr. Marion Sims' speculum sometimes very useful; but it is not so easily used, and requires an assistant, who is not always at hand. For operations, this and other vaginal retractors are indispensable, of course. The speculum used by Désormeaux, for the exploration of the cavity of the uterus, are of no great ser-

vice in practice. The use of the speculum has, doubtless, led to much rash practice; and topical remedies have no doubt often been used even when not required; but heroic practice in uterine diseases has, the author believes, had its day, and the speculum is now much more carefully used. This being the case, it is the part of a careful practitioner, to make use of an instrument, which rarely, if ever, indeed, can prove of the least harm to the patient, and which so often is useful in diagnosis, and also in treatment.

DISORDERS OF MENSTRUATION.

Menstruation is the sign that ("a woman") the ovaries have become capable of ripening the germ, which, being impregnated, will give birth to a fœtus. In temperate climates, between 33° and 54° N. latitude, menstruation appears about the fifteenth year. In the torrid zone, it comes on from the twelfth to the thirteenth year; and, in the frigid zone, it comes on between the fifteenth and sixteenth year, on an average. With regard to race, nothing very particular is known as to this point, nor concerning the influence which circumstances have upon the appearance of the flow. Many diseases appear at the epoch of the first invasion of menstruation, and the mortality of young women exceeds that of young men at that period of life. The sole fact, that a young woman has passed the epoch at which menstruation habitually appears, is no proof that she requires Medical advice, since some persons may begin to menstruate at ten, and others not until the age of twenty, and there are even cases on record where women have become pregnant who have never been menstruated. Dr. Aran, of Paris, in his "Leçons Cliniques sur les Maladies de l'Uterus," p. 282, mentions a curious case where a woman, the mother of nine children, had never menstruated, except when she was pregnant.

AMENORRHŒA.

Amenorrhœa, or non-appearance of the menstrual flow, may be produced either by the causes which prevent the accomplishment of the function, or by those which prevent the evacuation of the fluid. In the first case, we have to look for some faulty conformation of the uterus or ovaries. Sometimes both ovaries are absent, sometimes only one, and sometimes these organs remain during life in the condition of infancy, with scarcely any appearance of Graafian vesicles, in which case the patient is sterile. In a case which came before the notice of the author, there was, in a woman, æt. 26, imperforation of the os uteri, with a rudimentary condition of the mammary gland; and, although the os uteri was opened, and a sound passed into the uterus to the extent of two inches, menstruation has not appeared after an interval of many years. Absence, or rudimentary condition, of the uterus, is not so very uncommon. When the uterus is rudimentary, it may sometimes be advisable to use galvanisation either by the interrupted current, or the continuous current, one of the poles being introduced into the cavity of the uterus, and the other over the os pubis. Retention of the menstrual fluid may be divided into eight different species, according to their causes, which are:—Imperforation of the vulvo-uterine canal, congenital, or acquired before puberty; cicatrices after puberty; stricture of the vagina; pathological hypertrophy of the neck of the uterus; a foreign body in the cervix; flexions of the neck of the womb; spasmodic contraction of the organ; or, lastly, obliteration of the Fallopian tubes, either congenital or acquired. In the first group, the retention may arise, either from adhesions of the lips of the vulva, from imperforate hymen, absence of the vagina, or imperforation of the cervix uteri. A point to be noticed with regard to these causes of retention, is, that operations for their relief are all more or less frequently fatal. Among cases where retention ensues from some obstacle after puberty, we may have adhesion of the cervix to the wall of the vagina, or occlusion by cauterisation, or after amputation of the cervix, or after a severe labour, or after gangrene in typhoid fever, which may cause retention. Sometimes it fortunately happens that after a severe labour, or other

cause, which prevents the issue of the fluid, no more is secreted. The author has seen an example of this last year in the case of a woman, æt. 35. Then there may be congenital atresia of the vagina, or excessive tenuity of the os uteri; the mechanical causes of dysmenorrhœa, described with so much care by Dr. Marion Sims. Again, hypertrophy of the neck of the womb sometimes gives rise to retention, partial, or complete, of menstruation, and this may take place in cases of cancerous tumours, as mentioned by Dr. Bernutz, of Paris. Polypi may, in certain very rare cases, where growing in the cervix uteri, obstruct the passage of blood from the uterus; and also pseudo-membranous tumours may cause partial retention. In some cases, menstrual retention is doubtless caused by deviation of the uterus; and spasmodic contraction of the os uteri may lead to the same result. Congenital, or acquired, obliteration of the Fallopian tubes may, lastly, cause retention of the menstrual fluid. Both tubes have been found, in cases of amenorrhœa, to be imperforate on examination after death, and enormously distended with blood.

It is very important that the practitioner should be on his guard, in cases of prolonged amenorrhœa, that some of the conditions just mentioned may not exist, since the very rarity of cases of imperforate hymen may make him pass over a case, when it comes before him. The patient must be questioned carefully as to the possible existence of intermittent expulsive pains in the region of the uterus, returning at intervals of about a month. Sometimes the occurrence of peritonitis, limited to the pelvic cavity, may be suspected, from the occurrence of diarrhœa, especially when there is escape of blood into the pelvic cavity. In such cases a tumour may occasionally be felt in the retro-uterine space. The best diagnostic mark of menstrual retention is the regularity of the periodical expulsive pains. There is sometimes considerable difficulty in distinguishing between the retention caused by pregnancy, and that caused by the other circumstances adverted to, as well as to distinguish between disease of the ovary and retention, in some cases. With regard to treatment in imperforate hymen, the author has succeeded well in a case of the kind recently, by making only a pin's point incision in the membrane, from which the blood issued *guttatim*, and choosing the period of ten days, or thereabouts, after the pains of expulsion had been felt. When the vagina is absent, puncture by the rectum is not a good plan. It is better to use Amussat's operation for forming a vagina. Nor should the sound be employed in cases of atresia of the cervix and os uteri, which should be carefully incised.

Puberty, says West, is very tardy in idiots, in most cases, but in some cases the flow may be almost indefinitely postponed by the occurrence of fevers, or some grave disease. In cases of delicate health, or when chlorosis exists, menstruation may cease for a longer or shorter period. Some young women fall off in health on the appearance of menstruation, and gradually pine away and become affected with pulmonary tuberculosis. The chlorosis of pregnant women has been pointed out by several authors, such as Cazeaux and Kewish. The tendency of almost all diseases which affect the function of blood-making is towards amenorrhœa. Phthisis and cancer both cause it. Dr. Hérard, of Paris, in a paper "On the Influence of Fevers on Menstruation," shows that all fevers act alike on this function. Whenever any chronic disease causes cachexia menstruation languishes and disappears. No disease more rapidly causes derangements of menstruation than phthisis. The author has found at the North London Consumption Hospital that where cavities exist amenorrhœa is sure to take place in less than six months; and Raciborski asserts that the ovaries are always more or less atrophied in phthisical patients. Louis showed that amenorrhœa in phthisis usually coincided with the commencement of the hectic. The author cannot agree with Dr. H. Bennett that it is useful to treat uterine disease in such cases in any active manner.

Secondary syphilis also causes amenorrhœa. The non-evacuation of four to six ounces of blood per month cannot be usually of small consequence to the health of a woman; and in amenorrhœa we see symptoms of congestion of the liver and other viscera arise in many cases. In treating such cases of amenorrhœa our idea ought to be to improve the general health as much as possible by means of hygienic influences such as life in the open air and change of climate and occupation if possible, with hydropathic appliances, which are most useful, joined to carefully chosen drugs. Constipation may be amended by means of extract of aloes, and the compound iron mixture of the Pharmacopœia is often usefully prescribed. In some very rare cases menstruation seems to be imitated by bleeding from some other part of the body. Thus, the stomach, the nipples, the lungs, or the nostrils may all be the sources of more or less abundant periodical hæmorrhages at menstrual epochs. In such cases the organs of generation are usually healthy, and pregnancy has taken place in similar cases of amenorrhœa. The use of topical applications to the parts is to be tried in such cases. A warm sitz bath, morning and evening, with a small quantity of mustard in it, may be taken at the menstrual time, and nitric ether or spiritus juniper given in a draught. The author has had success in some cases of amenorrhœa by using the interrupted current (Stohrer's battery), one pole being placed over the pubes, and the other on the sacrum. Oil of savine is useful in some cases of obstinate amenorrhœa; but must be used with caution, and syrup of the iodide of iron is often serviceable. Neither mercury nor ergot of rye seem to the author to be even indicated. Medicines called emmenagogues have fallen into disrepute of late years since the discovery of spontaneous ovulation was made. A remedy which merely congests the organs, may not cause menstruation, but only hæmorrhage. It is only when the action of the organs is great enough to ripen the ovum that a slight stimulant to the organs in the shape of drugs is indicated. This is the *torpor* of Kiwisch, or the *asthenia* of Aran. Among other drugs useful in such a state, Trousseau advised ten minim doses of the tincture of iodine, the powder of rue in doses of twenty grains, or savine in powder in doses of ten to fifteen grains (or the volatile oil in doses of ten drops) may sometimes prove useful. Aloes was much praised by Schönleim and Scanzoni, and enemata of aloes in bad cases. Aran preferred the injection of ten drops or more of liquor ammoniæ in an ounce of milk into the vagina. Duchenne, of Boulogne, has recommended the introduction into the vagina of a double conductor so made, as to embrace the cervix uteri, and connected with an interrupted current of galvano-electricity. The galvanic pessary of Simpson is dangerous and useless. Cathetering of the uterus may succeed, but it is not prudent to make use of it in all cases. Leeches on the hypogastrium are not often of use, but may perfectly succeed in some cases. Among the curiosities of medicine a case is mentioned in the *Journ. Med.*, of Bordeaux, of September, 1861, in which a young lady, æt. 18, had hæmorrhage into the anterior chamber of the eye and epistaxis at the menstrual period. Grave inflammations of the uterus and ovaries or various forms of degeneration of the latter organs, or tumours in the uterus may arrest menstruation for an indefinite time. In some cases, menstruation ceases at an early age, as at 28 or 30, never to return. In some rare cases, menstruation may only last eight years,—i.e., it commences about 15 and ends about 45. According to one observer, M. Petrequin, the cessation of menstruation takes place at 40 to 50 in the case of the half of all women; at from 40 to 45 in a quarter; from 35 to 40 in one-eighth; and at from 50 to 55 for one-eighth. Cases have occurred where menstruation has lasted until the age of 65. The function is almost to be irregular both at the commencement and at the epoch of cessation.

It has been noticed by Dr. West, in his work on di-

seases of women, that venereal excesses often cause an arrest of menstruation for a time; and the author has also noticed this, that frequent masturbation is also followed in most cases by scanty and painful menstruation. Occasionally, however, excesses lead to profuse menstrual discharge. Parent Duchateles made the remark that prostitutes are very subject to amenorrhœa, and this probably is due in some measures to excesses. Cold feet, exposure to cold and wet may cause acute suppression of the flow; and the fear of becoming pregnant has, according to Dr. Raciborski, in the *Arch. di Med.*, 1865, t. j., sometimes caused suppression. Anger or grief may both cause sudden arrest of menstruation. In such cases a warm sitz bath, a turkish bath, or a cordial drink (such as twenty minims of spirits of sulphuric ether, twenty of spirits of lavender, and twenty of spirits of chloroform in an ounce of camphor water), may succeed in bringing on the expected flow. If this do not succeed, great care must be taken at the next menstrual time to endeavour to bring it on by the methods mentioned above in speaking of amenorrhœa.

(To be continued.)

ADDRESS IN MIDWIFERY (a).

By EVORY KENNEDY, M.D.,

Late Master of the Dublin Lying-in Hospital; President of the Section.

(Continued from page 121.)

CASE XIX. *Obstinate Procidentia of Uterus cured by Actual Cautery.*—Mary Burke, æt. 60, a widow with six children, had obstinate procidentia of the uterus, and could not retain any form of pessary. She suffered much distress; her general health was deranged; she was dyspeptic, and had lumbar pains. She was confined to the horizontal position, with the lips well raised, for a fortnight. The ulcers healed. The uterus was placed *in situ*, and astringent injections were used. The actual cautery was then applied about an inch and a-half from the vulva round the surface of the vagina for the extent of about half an inch. My clinical clerk, who was somewhat of the Gil Blas school, in criticising his master, adds that the old woman was so indignant at this operation, which, for obvious reasons, it was deemed more considerate not to explain beforehand, that she left the hospital in a fit of indignation, because a hot iron had been applied to her inside, as she said, without saying, "With your leave, or by your leave." She eventually permitted the treatment to be followed up by the application of nitrate of silver; and the report is thus continued by my clinical critic. At the expiration of two months, she was able to go about again. The uterus was *in situ*: and she had derived much benefit to her general health and condition, and a distressing pain, descending down the front of the thigh, from which she had constantly suffered, had disappeared. The cicatrix formed by the eschar prevented the descent of the os. He adds, however, this caustic comment on my operation: "She certainly got a regular touching up."

CASE XX. *Procidentia Vesicæ treated by Vaginal Mould.*—In February 1839, Catherine Sullivan was admitted with complete procidentia of the bladder, the result of a tedious and instrumental delivery of her first child. She had had two pregnancies, and suffered from prolapsus; but the protrusion occurred suddenly, about two years before admission, whilst she was lifting a feather-bed. She was treated by a variety of pessaries, and the actual cautery was applied to the interior of the vagina; but the protrusion recurred despite of all. She was kept for some time in the horizontal posture. A cast of the vagina was taken in wax, with the bladder restored to its natural position. A plaster of Paris mould was made from it; and in this a caoutchouc instrument was moulded. This she wore with great comfort and convenience. It should be mentioned that the difficulties in this case were added to

(a) Delivered at Birmingham, August, 1872.

by the existence of a growth supposed to be an exostosis, springing from the interior of the sacrum, and encroaching on the inlet of the pelvis.

CASE XXI. Inversion of Bladder, with Procidencia through the Vesico-Vaginal Septum.—J. S., æt. 50, suffered from lesion of the vagino-vesical wall in labour, to such an extent that the bladder protruded beyond the vaginal aperture to the extent of a small cricket ball. The loss of substance was such that no operation could possibly be undertaken, and the intolerance of pressure was so great that no attempt at reduction or support of the bladder *in situ*, as in the former cases, could be made or tolerated. A shield of tin was adapted to prevent friction, but its advantages were not very great.

CASE XXII. Procidencia of Uterus and Bladder, with Eversion of latter from Sloughing of Vesico-Vaginal Wall.—This case was also the result of a tedious and instrumental labour. The patient had been a miserable and hopeless sufferer for years. Nothing could be attempted, not even reduction within the vagina, with any hope of advantage. A tin shield was adapted, as in the previous case, to preserve the sensitive parts from friction. The ulcerations on the utero-vaginal wall, which you perceive in this drawing, were healed by the application of caustics, and she was discharged to wear out her life of misery and torture.

Whether the ingenuity of our operating surgeons will ever arrive, by adaptation of a plastic operation or otherwise, at any means of curing these apparently hopeless cases, is problematical. One comfort is, that the earlier use of instruments would appear to render these incurable cases less frequent; certainly we do not meet them as we did when the rule was to leave Nature day after day to her unassisted efforts.

CASE XXIII. Hypertrophy of Lips of Uterus.—I formerly described some cases of this affection occurring in the unimpregnated uterus, with operations for their removal. The drawing now exhibited shows this condition in the impregnated organ. It is, no doubt, a cause of tedious labour, and, when the lips of the uterus are caught by the head against the pubes, retards its progress. My case-books show several instances where delay was referable to this cause, and in which the head remained stationary until the tumid lip was pressed steadily up so as to relieve it from the pressure, when the labour progressed. In minor cases this is all that is necessary, but in more severe cases I have derived benefit from punctures. In Quinlan's case, now exhibited, attention was called to what was supposed by the pupil on duty to be a polypus connected with the upper and anterior part of the vagina. The head was at this time escaping the os, and pressed the tumour against the pubes. At noon, the head descended very little, but was forcing the tumour down before it. Two fingers were steadily kept against it during and in the interval of the pains, and the head descended to rest between the ischia, where it remained stationary, without making the turn into the hollow of the sacrum for ten hours. The pains became slack; there was no want of room; and the foetal heart was audible. I passed up the lever and brought down a living male child. This woman went out well and returned at a subsequent period, when the projecting growth was removed by curved scissors which I had constructed for the purpose.

CASE XXIV. Sudden and unaccountable Death on Fifth Day after Labour.—Mary Caulfield, æt. 30, was delivered April 14th, 1837, after a labour of ten hours. Her recovery was favourable. She was up for a short time on the 19th, apparently well, when she suddenly exclaimed, "What ails me? Oh, my God!" and almost immediately expired. After the most careful *post-mortem* examination, there was not anything found that could account for death. In a case of sudden death occurring some months previously in hospital, a dissecting aneurism of the aorta was found that had opened into the pericardium. It is quite possible that a lesion might have existed in Caulfield's case

also, that escaped detection; but every tissue in the body was examined most carefully, especially the respiratory, circulatory, and cerebral symptoms, and nothing abnormal could be detected.

CASE XXV. Funis Prolapsed; Long Forceps; Advantage of Stethoscope.—Biddy B. had her second labour in Nov. 1837. The funis was prolapsed, with rupture of the membranes. The os was fully dilated, and the head entering the brim of the pelvis. I replaced the funis within the uterus, and retained it *in situ* by pieces of sponge pressed up in the posterior and right side of the pelvis, where the funis had descended. This practice I had frequently before adopted with great advantage. However, on applying the stethoscope, the action of the foetal heart, that had been previously audible, became indistinct, and eventually could not be detected. My long forceps were immediately applied, and a healthy child was extracted, in which the respiration was speedily established.

CASE XXVI. Procidencia of Uterus and Vagina during Labour; with retained Placenta: Replacement; Recovery.—The last case to which I shall call your attention is one represented in this drawing, and which tells its own tale. The patient was sent into hospital as you see her, delivered by an ignorant midwife, after a labour of a few hours, with procidencia of the vagina. The funis was hanging out; the vagina lacerated at its superior part: the uterus was close to the external parts, and the placenta retained within it and adherent. There was little hæmorrhage, or she could not have reached the hospital alive. Reaction was established, and the uterus and vagina were restored to their natural position. The hand was slowly introduced into the uterus, and the placenta detached and removed. Fortunately, the laceration, which was flap-shaped, did not extend to the deep-seated tissues or bladder, and she recovered slowly but completely. She was retained for a long time in the recumbent posture; and the vagina and uterus kept their position without requiring artificial support.

PRACTICAL OBSTETRICS.—No. 3.

By FRANCIS E. CLARKE, B.A., M.B., T.C.D., &c.,
Drogheda.

AMID the varied incidents of our professional labours cases do occasionally occur which, although terminating unfavourably, yet from their rarity or power of affording illustrative information, are worthy a corner in our Medico-Scientific Press. The case I am about briefly to record is one of such, melancholy, alas! in the extreme, happily rare in its occurrence, and strikingly illustrative of several points of considerable importance.

Mrs. H., wife of a railway guard, æt. 25, apparently healthy, having arrived at the full period of utero-gestation in her first pregnancy, was taken in labour about nine o'clock on Sunday morning, August 18th. A midwife, who had been previously engaged, was in attendance shortly after. Everything appears to have gone on favourably (with the exception of diarrhœa, which it was said commenced the day before) until between five and six o'clock p.m., when the face became somewhat swollen, and within an hour the swelling had so extended in superficies as to involve entire chest, back, face, and arms. The midwife then asking for Medical advice, I was hastily summoned, and arrived about seven o'clock, when I at once perceived that emphysema of the subcutaneous areolar tissue had taken place, and had already advanced to a considerable extent. The eyelids were so far involved that the eyes could scarcely be opened, and the subcutaneous cellular tissue was infiltrated throughout the entire of the upper extremity that the least digital pressure produced the well-known crepitant sensation of emphysematous infiltration similar to the crepitation of "blown veal." Features, owing thereto, were much dis-

torted, countenance anxious, pulse hard, rapid, and weak. The os uteri was nearly dilated, head presenting. The midwife reported that the pains had not been unusually severe, but moderately regular, and labour had throughout advanced tolerably well, though slowly, as is usual in primiparæ. Recognising the rare and serious nature of the case I gave an unfavourable prognosis, and immediately requested a consultation. Within a brief period I had the advantage of having the assistance of the long and highly-cultivated obstetrical experience of Dr. Delahoyde, who agreed throughout with me in my views of the case. The pelvis was large, but the external genitals extremely small, and as I had administered a gentle stimulant just previous to his arrival we determined to let labour proceed naturally. A dead full-grown fœtus was expelled shortly after nine, when it was at once perceptible that there was another in the womb. Ergot being exhibited, and head presenting, we ruptured the membranes, but labour proceeded slowly, the head being unusually large, and expulsive power of pains feeble, so that we found it advisable to deliver with the forceps (first evacuating contents of the bladder with a catheter, though urine had been voided frequently during the day), this second fœtus being also dead. The placenta came away easily in about fifteen minutes with little if any hæmorrhage, but the diarrhœa, which had increased subsequent to the delivery of the first fœtus, became so excessive after the entire intra-uterine pressure was removed as to become quite choleraic in character and quantity. Such an intestinal flux I never saw before, save in Asiatic cholera. On inquiry regarding the nature of this I ascertained that she had not taken any purgative immediately previous to labour, but for fully the last two months of her pregnancy she had regularly taken pills of aloes and soap, which she prepared extemporaneously for herself. Notwithstanding every means used, brandy, opium (*per se*, and in combination with gallic acid, &c.), acetate of lead and opium injection, &c., this diarrhœa continued (but not so violent in character as immediately subsequent to delivery, which was beyond description, the sphincter appearing to lose all control, so great was the volume of the intestinal excretion). Although large doses of opium were administered there was no sleep during the night, respiration being difficult and laboured. Next morning pulse was completely imperceptible, owing to amount of emphysematous infiltration, which extended down to the tips of each finger; tongue thickly furred; cold clammy perspiration, and respiration quick, painful, and laboured. I drew off about a pint of dark coloured urine with the catheter, and ordered beef-tea, brandy, and a mixture antispasmodic and astringent. I had a consultation shortly after with Dr. Delahoyde, but our patient succumbed between four and five o'clock p.m. (the day after delivery).

Emphysema is of rare occurrence during parturition, at all times a serious accident, but in complex labour, owing to plurality of birth the chances are of course infinitely more against the patient than otherwise. In this case, once the pulmonic cell ruptured, and the accident happened, I believe nothing could have saved the patient, the emphysema spreading so rapidly and extensively. The urgent hypercatharsis illustrates well the accumulative property of aloes; during pregnancy its nightly imbibition produced scarcely a moderate stool, but immediately labour set in reflex action induced its cathartic hydragogue effects, and once the intra-uterine pressure was withdrawn the intestinal flux attributable thereto became uncontrollable. This, in any case, would have been most alarming, and fraught with more than ordinary danger, but laying it aside altogether the emphysema would in all probability, as it did, cause death. Both fœtuses were very large, much above the average size, and had the uterus not been enlarged so extremely such accumulative effects might not have followed the injudicious and frequent use of aloes, nor in all probability would emphysema have taken place.

Of course, the emphysema was interlobular as well as sub-cutaneous, but of its exact pulmonary nature, and

whether as well sub-pleural, mediastinal, or neither, it is impossible to speak authoritatively, as auscultation subsequent to my seeing the case was out of the question, and an autopsy would not have been permitted. It would have been most interesting to examine the state of the lungs, as of their previous structural or functional conditions I am alike ignorant.

The case I should say is almost unique—plurality, emphysema (*a*), and choleraic diarrhœa, and one beyond the pale of Medical science with which successfully to cope. When such instances occur in the course of our professional careers in what a gloomy shade appears the picture of our Medical achievements and modern progress! What triumphs death still too often has!

“Quid faceret? quò se, raptâ bis conjuge, ferret?
Quo fletu Manis, quâ Numina voce moveret?”

P.S.—Since the foregoing was written I have been informed that Mrs. H. was considered to have *delicate lungs*. Strange to say also, she had lost a sister in her first confinement, but from what cause I did not hear.

MARRIAGE IN THE ARMY.

BEING THE FIRST OF A SHORT SERIES OF ARTICLES ON THE RESULTS OF EARLY MARRIAGES, STERILITY, FERTILITY, FEVERS AFTER DELIVERY, PECULIARITIES OF LABOURS, INFANTILE MORTALITY, INFLUENCE OF CLIMATE, &c.

By FRANCIS R. HOGG, M.D., R.H.A.,

Fellow of the Royal Medico-Chirurgical and Obstetrical Societies.

BEFORE entering into professional details, and reporting on the health of soldiers' wives, it may not be out of place to give a few extracts from a pamphlet written for pastime during sickness, about two years ago.

The “Queen's Regulations” state that “commanding officers of regiments, who have ample experience of the very great inconvenience arising to the service and to the public from the improvident marriage of soldiers, are to discountenance such connexions, and to explain to the men that their comforts as soldiers are in a very small degree increased by their marriage, while the inconvenience and distress naturally accruing therefrom are serious and unavoidable, particularly when regiments are ordered to embark for foreign service.” But with all this warning, there are 823 soldiers' wives in Woolwich married with leave, and 1,646 children depending upon them; 106 are accommodated in the Common cottages, 120 in the Cambridge cottages, 25 in the huts, and a good number in the barracks—staff serjeants, as a rule, having two rooms, the others one. Many are on the lodging list. In the Cambridge cottages there is one family with seven children, one with six, and six families with five children. In the Common cottages there is one family with seven children, five families with six, five with five, nine with four. The number of married quarters altogether is 499. Lodging money amounts to 4d. a day, unfurnished lodgings vary from 2s. to 5s. per week, but for 4s. 6d. a very fair furnished lodging can be obtained. The Common cottages are very fair, the Cambridge cottages still better. For a moment, let us look at the married soldier's home. He will probably occupy one room, sixteen feet long, ten feet high, twelve feet broad; too often the door will be kept shut, the sweet fresh air excluded, the windows closed, the light kept out by curtains and plants; on the floor will be old unwholesome carpeting, harbouring dust and dirt—and in this amount of space, I have met with large four-post beds, with the usual amount of curtain; also birds, cats, and even rabbits. In this atmosphere a man,

(a) Two cases of subcutaneous emphysema occurring during course of natural labour may be found reported by Dr. Pratt, in the issue of this Journal for May 25th, 1870. Another case I heard the late Mr. Maurice Collis relate as occurring; I think (if I remember aright) in the practice of Dr. Sibthorpe.

his wife, and four children eat, sleep, and live, and after a time are poisoned by each other's breath. Sickness results (especially when on wet days women will dry clothes in their cottages). Here, in Woolwich, overcrowding in quarters is at times unavoidable, but prolonged experience only convinces me that, excepting in the case of large families with six and occasionally seven children, the best of health ought to be enjoyed in the Common cottages or the Cambridge cottages, and in many rooms in the barracks.

Let us consider a moment the position of a married gunner living at Woolwich in the cottages. His daily pay is 1s. 6d.; he is clad, housed, allowed fuel and light, the advantages of cheap food at the canteen, no taxes, his cottage kept in good repair, supplied with bed and bedding, and a few necessary articles of furniture; he has the use of the recreation rooms, the opportunity of admirable education for his children, indefatigable clergymen, free medical and hospital assistance for himself and family, reasonable prospect of professional advancement, and after a certain number of years he is pensioned. Ten per cent. of all ranks are allowed to marry. Good conduct badges bring in each a penny a day extra. The rations—consisting of 1 lb. of bread and $\frac{7}{8}$ lb. of meat—the soldier has for 4 $\frac{1}{2}$ d., which, in the town, would cost at least 7 $\frac{1}{2}$ d. Men get extra pay, and earn money as farriers; shoeing-smiths have 10d. a day extra; collar makers, 7 $\frac{1}{2}$ d.; wheelers, 7 $\frac{1}{2}$ d.; smiths, 1s.; tailors and shoemakers, what they can earn; and grooms and officers' servants are frequently the best off of any. Men also work at the canteen. The wives of gunners have, on an average, nine men's washing at 1d. a day per man, all profit, with the exception of soap, soda, and $\frac{1}{2}$ d. per diem for the use of utensils in wash-house. Some wives also are allowed to make six shirts a week, receiving 7d. a shirt.

As regards number of sick, a few days ago, on inquiry, the information was kindly supplied by the registrar, that out of 275 men in the Herbert Hospital, only ten were married men. Also that last year 4,423 patients were there treated, of whom 199 were married. These are remarkable contrasts, until it is taken into consideration that the majority of men are single; that married men, for the sake of their families, strain every effort to keep out, whilst bachelors are often very glad to get into hospital. For instance, during ten years about 5,000 cases of venereal diseases have been treated at the Herbert Hospital.

On the subject of married without leave, the condition of soldiers' wives so placed is so pitiable, so hopeless, that to prevent for the future the recurrence of such misery, the only remedy one can suggest is, that no marriage should be considered valid without the written sanction of the commanding officer being first received by the officiating clergymen. To afford advantages, in humanity and charity, to these unfortunate people, too frequently infringing on the privileges of those fully entitled, besides encouraging others to repeat this cruel, heartless crime—for crime it is, to take a young girl from home or elsewhere to lead a life of starvation."

Coming to the present state of affairs, the question arises, until conscription takes the place of competition with the labour market, which is the best, plan to employ young active bachelors ready to move at any moment, always smart, and under constant supervision, or else to encourage matrimony?

The bachelor sometimes dissipates, deserts, or ruining his constitution, becomes in hospital ineffective, then invalided. The married man is a very expensive luxury, but without the objections applied to bachelors. It is a finance question in time of peace, but when war comes consider the number of widows and orphans, the amount of pensions married men would involve, whereas the bachelor, free from care, a cheaper article, makes a splendid soldier, without the slightest excuse or wish to shirk danger.

Digressing a little, the question has often been asked re-

garding the number of men who in civil life would be Medical students, clerks, gentlemen, and so forth, and how they get on. There are wonderful instances I could tell you of several officers now in good positions and well married, having risen from the ranks, but who educated themselves. And why not? there is plenty of scope and opportunity. Honestly looking back many an army doctor would confirm the statement that a well conducted lad would do much better enlisting than drudging in trades or professions. But the so-called gentleman who comes to grief in London dissipation, the black sheep of the family who disgraces his parents, robs his sisters, and then as a last resource enlists, he never does any good. The other recruits delight in dragging him to their level; there is no favour shown to the man who clings to the order he has disgraced. On one occasion an assistant-surgeon passing men for India stumbled across the brother of a young lady of his acquaintance, one of these "gentlemen" who nearly broke his mother's heart; no difference was made, he was carefully examined and dismissed without a word in spite of his swagger. If people only knew the full advantages there ought to be no difficulty in getting a good class of recruits.

Turning from this knotty point, let us venture into an untilled field of inquiry to discuss the health and Medical points respecting soldiers' families, thousands of whom have been under observation and treatment during a subordinate service of fourteen years.

About 15 per cent. of soldiers' wives are soldiers' daughters, born on board ship, on the line of march, and reared in barracks—a rough school; some the offspring of mothers murdered in the Indian mutiny; others the orphans of soldiers suddenly swept away in terrible epidemics at Bermuda, Malta, Mauritius, and by fever in China, by cholera, dysentery, and sunstroke in India, and who have been adopted by an old comrade. Rarely, but occasionally, are the daughters of professional men met with as the wives of private soldiers. Taken altogether, the remainder chiefly consist of the children of agricultural labourers, and labourers, tradesmen, and sailors.

A large, healthy, fertile, cheerful, improvident class come from Ireland, a few from Wales, the wealthy from England, especially from London and Devonshire. The most comfortable homes are found amongst the Scotch; no debt, dirt, or sickness; the husbands, ruled with a rod of iron, wonderfully steady; and the least satisfactory people to deal with as regards cleanliness, common sense, hygiene, and constitutions, to work upon are women who, from long residence in hot climates, become helpless and lethargic: when sickness comes, they swear by brandy, only rapidly to run down hill.

Intemperance.—The drunkard's home is much the same all the world over; there are no more sots in the army than out of it, considering the terrible increase of this vice. The Lancers, recently stationed here, constituted a splendid dashing regiment, well conducted and healthy; the women a very superior class, of whom the few under Medical treatment made rapid recoveries; the majority very temperate. In 1870 there were 211 teetotallers amongst the men in garrison.

Morality.—Religions professed run somewhat in the following proportion: Church of England, 1,392; Roman Catholic, 435; Presbyterian, 150; Wesleyan, 67; Non-conformists, 18. Making allowance for circumstances, associations, and surroundings, a very honest, hard working class. Illegitimate children, or adultery, very exceptional. One woman in remorse poisoned herself with vitriol. Very little syphilis met with, or to speak more properly, very few cases diagnosed secondarily amongst the wives, but the children of a drunken, syphilitic, liver-diseased father, die early of brain and abdominal affections, or survive to swell the ranks of idiocy and scrofula. My statistics show that a third of the children born to soldiers die of convulsions, dysentery, or diarrhoea.

(To be continued.)

CASE OF FATAL PUERPERAL SCARLATINA.

By FRANCIS M. LUTHER, M.D.

Mrs. DAVIS, æt. 28, secundipara, confined naturally and speedily on the 30th June. I was present, but only interfered so far as to remove the placenta. There was no hæmorrhage. I had been attending a case of scarlatina for a fortnight previously, and used to remain a considerable time in the sick room. There were likewise cases of scarlatina a few doors from Mrs. Davis' house. On the third or fourth day she got a slight rigor followed by thirst, vomiting, and diarrhœa, with some malaise about the epigastrium, and a feeling of weakness. Her tongue was of a brilliant scarlet, but not glazed or dry; pulse not much accelerated. No difficulty in swallowing or sore throat. I was not well myself while attending this case, and not anticipating that it would end fatally, did not take daily notes of its progress; but it was remarkable for the absence of salient symptoms. There were, in fact, none others than those I have mentioned till the 9th of July, when the tongue got aphthous. On this day she said the diarrhœa, previously incessant, had ceased, and asked when might she get up, as the bed was weakening her. During the night diarrhœa returned, and next day she got collapse and died without any suffering. There was no delirium. Livid patches became noticeable on the body before death. While attending her I noticed once a measly eruption on the face, but thought it a scorbutic manifestation to which she was subject. She made so little complaint, and was by nature so delicate in appearance, that I did not perceive the gravity of her case; the more so as for seven years, or nearly, no woman whom I attended in labour had died. A run of luck makes one over-confident. The treatment I pursued was at first giving grey powder and castor oil, and afterwards, under the impression that it might be scarlatina, carbonate of ammonia and sulphurous acid (not on the same days, of course). I also gave aromatic powder, and used turpentine stupes to the abdomen. However, I do not think those remedies were carefully administered, for the young woman had no nurse and depended on the neighbours. I kept her principally on whey and arrow-root, with a very little wine. One day I found her sipping whisky and water, and said I did not think she required it as her pulse was good, not quick, and not weak for her. In a sort of lying-in fever that she got some eighteen months before, I allowed her a good deal of wine and beef-tea. It came on five weeks after labour, was characterised by intense congestion of the lungs and nocturnal delirium. She would get a rigor, and next day a pyemic abscess would appear on her wrist and again on her shin. The latter healed on being opened, but the former discharged for a very long time; when it healed, the hand got swollen and inflamed, a minute eczematous eruption appearing upon it. When this subsided, the hand hung dead from paralysis of the extensor tendons, and, from the same cause, semi-luxation of the carpal end of the ulna occurred. She was confined to bed for six or eight weeks, and was much longer in regaining her strength. In that fever there was no diarrhœa. She had all the aspect of one liable to consumption; indeed, the abscess on the wrist was supposed to be scrofulous, but as it was immediately preceded by a rigor, and occurred in the course of a fever though so long as five weeks after labour, I considered it of pyemic origin, particularly as the occurrence of another rigor was followed by another abscess on the shin. I did not come to any certain conclusion that the malady of which Mrs. Davis died was scarlatina. It might have been a sort of typhoid. I regret I did not give stimulants freely from the start, as McOlinock recommends, and that a second dose of castor oil was given without my knowledge by a friend of the patient. Purgatives should be avoided in puerperal scarlatina. Some four months before

this Dr. Hartland, of Villierstown, while acting as my locum tenens, attended a woman in labour, and she got scarlatina but recovered. The rash came out strongly, the throat was sore, and she was delirious. Hers was the first case of scarlatina in my district, but Dr. Hartland had been attending cases of it.

Hospital Reports.

METROPOLITAN FREE HOSPITAL

Under the care of DR. DRYSDALE, reported by Mr. WM. KIPLING.

PATRICK WOODS, admitted April 29th, 1872.

History.—Aged thirty-six. Occupation, a horse-hair curler.

Present Attack came on three years ago (ten weeks after a sore on penis); he went to work one morning quite well, but in an hour's time he fell on his side unconscious; does not know how long he was so, but when he came round he had lost his speech completely, and the use of his right arm and leg; could hold his water and fæces well. He was laid up three months, and has never recovered, but is a good deal better than he was.

Present State.—There is loss of power in his right arm; cannot flex his fingers on his hand, or hand on forearm; can bend his forearm on arm slightly. Pronation and supination are lost in his forearm. On lying down he can raise his right leg from the bed, he can also stand on it pretty well; cannot flex the foot on leg, or bend the leg on thigh; sensation is good in it.

Tongue is protruded straight; pupils equal; right angle of mouth is higher than left; can close his eyelids; can blow out his mouth without air escaping; complains of no pain anywhere; memory is as good as before the attack. Is a strong, muscular man.

Speech is a good deal affected; can say yes and no easily, but cannot mention his own name—saying pots. He cannot pronounce the following letters of the alphabet:—B C D E H J K Q T U W X Y Z, but gives some other word for each; but the rest of the letters he can manage pretty well.

Ordered Potass iodidi, gr. x.;

Aqua, ℥j., t.d.s.

To be galvanised daily with the secondary current of Stohrer's battery.

May 7th.—Has had the various groups of muscles of leg and arm galvanised daily; he has very fair motion in his shoulder joint, being able to flex his arm on his chest; he can bend his forearm on his arm better, but cannot flex or extend the hand or fingers. He has the muscles of the tongue itself—those between it and the hyoid bone, and the latter with the larynx, galvanised daily; also the oral muscles. The patients in the ward also practice him with the letters of the alphabet, and his speech is better since admission. He can now use his leg pretty well, with the exception of flexing his foot on his leg, which he cannot manage very well. There is no wasting of muscles of leg or arm. Urine normal.

May 21st.—Much the same as above, and is now ordered the continuous current of Pulvermacher's battery.

May 31st.—Not much improvement with the above, but he can move his right arm pretty well in all directions; can flex and extend the forearm on arm to a moderate degree. No improvement in pronation and supination; cannot flex and extend the hand or wrist, and the fingers are a good deal contracted; cannot flex the foot on leg well yet, or the toes on the foot.

Speech is a good deal better, and he has most difficulty in pronouncing the letters B D E H K; the others he can manage pretty well.

July 1st.—Discharged: much in the same state as at last report.

SOCIAL SCIENCE CONGRESS.

THE annual meeting of this Association has gone off well. It was held this year at Plymouth. The Health Section was presided over by Dr. Acland; and we are able to give our readers the following abstract of his address:—

For the first time in our history an office has been formed for the regulation and amendment of the destitution of the greatly increasing population of our country, and in the last Session another step was taken, that of committing to the people themselves the charge of their own health. His object was to endeavour to give a sketch of what is comprised in the idea of health, and then to consider what are the circumstances of this country in respect of that conception. The public health does not consist in the health of individuals, but in all those circumstances which affect the body politic. The term national health includes a further idea; it includes the idea of all circumstances, not only that affect a nation as a whole, but the whole of the individuals which compose it. Then we have a comparative national health, that health which affects and is affected by the circumstances of the whole world; the nations comparing among themselves the reasons why one is more healthy and one less healthy than another, and presenting to the mind the conception of the fluctuations and circumstances of the whole human race. The circumstances which affect these several ideas were very simple; but the cardinal idea of health, of public health, of national health, and of comparative national health, were all different. The cardinal basis of national health was a wise education. For the next subject he would take only three illustrations, carefully selected. When an expert in sanitary matters mentioned the word "hospital" there immediately arose in his mind a conception of what is called a hospital unit. This, technically called a "ward," is that place in which patients live, and if they have no convalescent home they live there always. Therefore it has to be made as perfect as possible for the purpose of health, so that in the general arrangement for the beds all those circumstances were considered which were requisite for placing a person in a healthy position, and then the unit may be occupied by any number of persons that was thought fit. The units may be arranged in a great variety of manners; so that the skilful architect will be able to lay out the building in the most desirable way as soon as he sees the ground on which he is to build. Having a sick man, the first thing to do is not to treat him for his sickness, but to place him in the circumstances of health. For a sick village, a sick town, a sick navy, or a sick army, we do the same. The same cardinal principles have to be applied somehow or other to each individual of the whole. He wished next to present, in a similar hasty way, the fundamental conception of sickness, because as the object of the health department of the association was to handle disease, and so to promote health, we cannot help remembering that disease is a necessity as our world is constituted, and that we have to provide means for the treatment of disease as well as for the preservation of health. What is disease, and how is it to be studied? The answer to this question was furnished by several illustrations of practical work in this direction, and especially by an account of the investigation of the Norwegian Government with regard to leprosy, of the report of the College of Physicians of London on the same disease, and of the work of the Indian Sanitary Commission and of the Medical Department of the Privy Council with reference to the propagation and diffusion of cholera. He next referred to a diagram illustrative of the comparative sanitary condition of different countries, taken from Johnson's *Physical Atlas*. The diagram is 20 years old, and would show, if it were based on correct data, the rate of mortality in all the chief countries of the world. The mortality in New Zealand was stated at the small rate of 100 per 10,000 per annum; in Norway, 20 per 1,000; Prussia, something under 30; and so on; but in reaching the warmer climates the mortality was greater, that at the River Ganges being 700 per 1,000. He did not vouch for these figures, because they were only approximative, but that was the way with all those questions. We must endeavour to find out the way of getting at the precise data of mortality—the rate of life in all civilized portions of the world; and then how briefly they might be expressed; and if he, a poor provincial physician, might presume to ask a request of the great leading journal (*The Times*), he would ask that, instead of putting these figures, as it now does, in a paragraph, they might be put in a form of a diagram. Such is the astonishing success of inquiries made that the Registrar-

General is actually able to tell us at breakfast once a week how the people are getting on not only in Oxford, London, Manchester, and so forth, but he tells also of New York, of Vienna, of Turin, of St. Petersburg, of Bombay, and of Bengal. We have therefore health, public health, national health, and this amazing rising science of comparative national health so roughly sketched; and now the question is: What are poor mortals to do? Mr. Gladstone has said, "Oh, well, so far as England is concerned, hand them over to the guardians;" and he thought Mr. Gladstone quite right. (Hear, hear.) The conception rested upon the conception of the nature of modern civilization, and all the possible future of this nation; and the question was this: Who will manage this country in future, the people or the despot? Are you going to make the people take care of themselves, or are you going to treat them like children, and in the type of the worst feudal times? What the poor working man cannot do, the Government is bound to do for him. These are the proper objects of legislation. Nothing is too minute for the attention of the legislator; but his action must be based upon that principle. When Mr. Goschen, in the course of the last year or two, introduced his sanitary measure, it came in contact with the enormous question of local taxation, and the consequence was that his Bill had to be withdrawn. Mr. Stansfeld, in the Act of 1861, with a rare combination of sagacity and impetuosity, introduced three sides of a sheet of foolscap, in which he placed this principle before the Legislature—that the care of the public health should be in the hands of a first-class Cabinet Minister, possessing within his office all the elements requisite for supervising the whole health of the nation. He was taunted with taking a narrow view of the question, and when the Bill was read a third time and passed in the House of Lords, some of the newspapers actually did not notice it. Dr. Acland next considered the chief matters which are comprised in the cardinal ideas on the inquiry concerning health. He had twenty-nine of them, and there was not one which could be properly left out of legislation concerning national health. There were many questions to be asked with regard to hospitals. Should a county hospital, because it is supported by voluntary contributions, be exempted from inspection? On the list he had one subject which may not at first seem to have much connection with public health and local government—namely, the reorganisation of charities. It seemed to him impossible that we should go on for another quarter or half a century without dealing with this subject, without seeing that there is no waste of the energies and powers either of Governments or individuals in caring for those who need care. Instead of committees squabbling as to who was and who was not eligible for aid and matters of that sort, there must be a combination of the powers of the State and with those of individuals on this subject, or, in point of fact, they would come to a dead lock. That was his answer to the sharp criticism that we sometimes hear as to the impropriety of collecting in one central office what is called the care of destitution and the care of health. The two subjects are inseparable, and in the present state of civilisation it is necessary that in some form or other these two great departments of State should be united. In adopting that plan the Government of Mr. Gladstone proceeded upon the wise principle that, instead of waiting till they could construct a perfect theoretical system, they would avail themselves of the existing institutions and habits of the country. In resting upon the local self-government of the country for the administration of this vast subject Mr. Gladstone followed the principle which has made England what she is. He relied upon the principle which has made her people self-reliant, and therefore capable. He recollected that he was dealing with a practical people—with the practical people whose forefathers, sailing from that port, laid the foundations of the American Republic, gaining for their country new worlds and new reputations; and this people, when they have duties assigned to them, and are told calmly and kindly how they are to discharge them, will not refuse to act up to their character as Englishmen. There is one thing, however, in the Act which he would wish to see repealed. It is absolutely necessary that there should be attached to the office what are called experts. A scientific expert is not necessarily a man who has not succeeded in his profession, and wishes to be delivered from the trouble and care by a Government salary. What is necessary is, that whoever our scientific experts may be their opinions should be able to stand such a test as the opposition in a court of law of his friend Sir John Coleridge, and the evidence of such men as Letheby, Frankland, and Liebig. It is not enough to send down experts in

the profession to lay down the law before Guardians; they have got to remember that the English people would resist a doubtful opinion in a Court of Law, or on appeal. The point is very easily met. What is wanted is not that the Local Government Office should pay experts large salaries, but that the services of the most eminent scientific men should be retained, and that they should be paid fees for their opinions. In this way you would be able to get the best opinions which the world can produce, and to avoid any subsequent contest in a court of law. He believed that the Public Health Bill—and he had carefully abstained from having any communication with members of the Government upon the point—has conferred upon the great central authority and upon the very competent person who holds the chief position in it the power to drive the country into such measures in the several localities as may be desirable, and to obtain the assistance of any number of experts to aid him and the local authorities in their honest and upright endeavours for the promotion of the national health. With regard to the legislation of the next Session, Dr. Acland said he would not take the responsibility of urging the Government to take up further action next year. He earnestly desired there might be no Public Health Bill in the next Session, and that the power of the Government should be given to the question of local taxation. His reason was perfectly plain. We cannot expect to treat this public health question with finality; and local taxation must be settled before completing arrangements for the payment of new officers, and even for assigning to them their proper duties. He would implore the Association to support the Government until they see what are the effects of the existing laws, and until the local authorities throughout the country have had time to mature their plans. It is only waiting for a few months, when both parties in the House of Commons might combine together to prepare a permanent sanitary code and not a mere consolidation. In conclusion, Dr. Acland pointed out that healthy minds were dependent on healthy bodies.

REGISTERED FOR TRANSMISSION ABROAD.

THE
MEDICAL PRESS AND CIRCULAR

published simultaneously in London, Dublin, and Edinburgh, every
Wednesday morning. Price 5d. Post free, 5½d.

POST FREE TO ANNUAL SUBSCRIBERS £1 2 6
" IF PAID IN ADVANCE 1 0 0

* Post-office Orders and Cheques to be drawn in favour of—
A. A. TINDALL, 20, King William Street, Strand, London, W.C.
A. H. JACOB, Molesworth Hall, Molesworth Street, Dublin.
MACLELLAN and STEWART, South Bridge, Edinburgh.

SUBSCRIPTIONS FOR FRANCE are received by MESSRS. BAILLIÈRE, Publishers to the Académie de Médecine, Paris—post free in advance, £1 6s. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by MESSRS. WILLMER and ROGERS; Baltimore, by MESSRS. KELLY and FRET; Philadelphia, by MESSRS. LIPPINCOTT and Co., and DR. BUTLER, post free in advance, £1 6s., about six and a-half dollars; or direct from the Offices in this country for the same amount, by the new Post-office Order system.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 25, 1872.

THE PUBLIC HEALTH ACT.

THE Public Health Act has given rise to so many inquiries on the part of our correspondents that we may as well enumerate its chief provisions once for all, so as to enable them to consider fully their position, and peruse

or take part in the discussions that may follow. At the same time we should advise all whom it may concern to procure a copy of the Act, which contains sixty sections of a rather incongruous nature. Already copies of the Act have been sent by the Local Government Board to all town councils, boards of guardians, and other local authorities, with a circular explanatory of the provisions of the Act. Poor-law Medical officers will, no doubt, usually be able to consult this circular, and are likely to find it of use. Another circular is being prepared respecting the duties, qualifications, salaries, &c., of Medical officers of health in those cases in which the local authorities desire their salaries to be partly paid out of the national exchequer.

The Act is rather one of consolidation and rearrangement than anything else. A number of discordant authorities are quietly extinguished, and sanitary powers are henceforth confided to urban and rural authorities defined by the Act, and under the control of the Local Government Board. Medical Officers of Health and Inspectors of Nuisances are to be appointed by the new health authorities, and half their salaries will, under certain conditions, be paid by the Imperial Government. The Corporation of London is to take charge of the Thames, and with Dr. Letheby as Medical officer to the city, there can be little doubt that the sanitary authority of the port of London will be wielded with wisdom. The Act does not extend to Ireland or Scotland. We now state the effect of some of the clauses.

Sixteen are devoted to urban and rural sanitary authorities, into which the whole of England is divided. Urban sanitary authorities consist (1) of the corporate body of a borough constituted such either before or after the passing of the Act, (2) or the Improvement Commissioners of an Improvement Act district, or (3) the Local Board.

The boroughs of Oxford, Cambridge, Blandford, Calne, Wenlock, Folkestone, and Newport in the Isle of Wight are excepted. Cambridge will be deemed an Improvement Act district, and Oxford will be included in the Local Government district.

Rural sanitary authorities consist of the guardians of any Union which is not within the area of an urban sanitary district.

All Local Government Acts, as well as the Public Health Act of 1848, remain in force in urban sanitary districts and the new authorities, rural or urban, take all powers possessed under the Sewage Utilisation and Sanitary Acts, the Common Lodging Houses, the Diseases Prevention, and the Bakehouse Regulation Acts.

Every urban and rural authority is to appoint a Medical officer of health and an inspector of nuisances, whose appointment is to be subjected to the same conditions with the Local Government Board as now exist relative to the appointment of parochial Medical officers.

The inspectors of the Local Government Board may attend the meetings of urban and rural sanitary authorities.

In reference to port sanitary authorities, the Local Government Board may constitute any sanitary authority on the edge of any port the sanitary authority of that port, with power in accordance with the provisions of the Sanitary Act of 1866 over all craft moored therein.

Clauses 22 to 32 comprise alteration of areas and empowering the Local Government Board to declare any rural district an urban district; and also regulate the union of districts.

Clause 33 refers to the repeal of local Acts, and provides for the payment of compensation in cases of abolition of offices; and there are nineteen miscellaneous clauses referring, among other matters, to the transference of the working of the Metropolis Water Acts and the Alkali Act from the Board of Trade to the Local Government Board, to the provision made for the salary of the Medical officer of the Local Government Board, to the transfer of all officers and others employed for the purposes of the Act, to powers for the ordering the destruction of infected bedding, &c., and to the imposition of penalties on any persons who wilfully disobey sanitary regulations.

These are the chief provisions that interest Medical readers, but as we have already said, those immediately concerned should obtain a copy of the Act.

SIXTEEN YEARS' SANITARY WORK.

WE have before us the sixteenth Annual Report made to the Vestry of St. James's, Westminster, for the year 1872, by Dr. Lankester, Medical Officer of Health for St. James's, Westminster, in which we find a summary of his sixteen years' sanitary work in the district. The average death rate of the parish for the past 16 years has been 730; it would appear that upon an average there have been sixty less deaths every year since his sanitary operations commenced. Every one must feel that human work is carried on by human life, and that the result of work is wealth. The value of human life is therefore a calculable quantity. The charges for funerals, for illnesses, for work not done, for poor's rates, all the results of disease and death, can be easily estimated. He calculates that the sum thus saved to the community at large could not be less than £50,000.

In 1857 he was requested to draw up a special report, in preparation for cholera, which was made to the Vestry on the 15th of October. The recommendations there made were more or less immediately carried out. During this year he also drew up two handbills, one containing directions for the preservation of health, and the other directions for preventing the spread of infectious diseases. These were the commencement of a series of handbills which he drew up, and which have done a great deal of good in many parts of the country. Some of these have been reprinted and circulated in various towns of England.

In 1858 his attention was called to the overcrowded and unhealthy condition of those cellars and kitchens which had been let for the occupation of poor families during that year and the preceding ones. Sixty-two kitchens were condemned as being occupied contrary to the 103rd Section of the Metropolis Management Act. Since that time it required constant attention to prevent them being repopulated. The getting rid of the unhealthy population of the kitchens was undoubtedly a cause of the diminished population and increased salubrity of the parish.

In 1859 he pointed out that a large number of stables, cow houses, and slaughter houses were situated in the midst of thickly-crowded populations, and could but act, through the decomposing animal matter by which they are accompanied, injuriously on the health of the inhabitants of the houses near by.

In 1860 he was appointed analyst under the Adulteration Act, but without a proper laboratory for carrying out the provisions of it. He, nevertheless, made extensive analyses of articles of food, and much good has been done by the knowledge of the fact that he was ready to undertake the analysis of any article of food that was found to be unfit for eating, or improperly adulterated.

In 1861 his most especial business was the inspection of the bakehouses of the parish. The great majority of them were found to be free from objections on the score of the health of the persons employed.

In 1863 the cow houses, which had become a great nuisance in the Parish, were put under supervision by the aid of a clause in the Amended Metropolitan Act of 1862. The slaughter houses were also put under surveillance through the same Act, and the magistrates refused to license houses for slaughtering under ground.

In 1864, the Sanitary Inspector was chiefly employed in carrying out a house to house visitation, for the purpose of discovering persons who were unvaccinated. Upwards of one thousand families were visited, and upwards of one hundred and forty children were found unvaccinated. During this year the largest mortality occurred of any year during the sixteen of which he had been Medical Officer of Health. He undertook to investigate the causes, and showed in his Report that the death was due to the extreme cold of that year. He also brought forward that year the necessity of a more accurate registration of deaths, and a petition was presented to the Home Secretary on the subject.

In 1865, the very evident increase of diarrhoea and the existence of cholera on the continent of Europe, led to the adoption of immediate steps for meeting any outbreak of this disease in the Metropolis. It was in this year also he made extensive inquiries into the condition of persons in the various work-rooms where tailors and milliners were employed. This led to a large improvement in the condition of these work-rooms, as everywhere the proprietors were glad to receive instructions with regard to any improvement for the benefit of their workpeople.

In 1866, as had been anticipated, the cholera came. First, an unusual amount of diarrhoea, then true cases of cholera. The epidemic spent its strength in the East of London; but in St. James's, Westminster, there were eight deaths.

Notes on Current Topics.

Appointments in the Carmichael School, Dublin.

IN the appointments recently made at the Carmichael School of Medicine, we are happy to observe that the proprietors have exercised a wise discretion in selecting for the important posts vacant two gentlemen who have not only distinguished themselves as teachers, but have also proved their ability to undertake and conduct original physiological investigations. Drs. Yeo and Harvey undertake a responsible position in their accession to the Physiological niche so long occupied by Dr. Robert McDonnell, and their characters as experimental investigators give promise that they may worthily carry out the work so ably begun by their predecessor.

Cholera in India.

THE malignity and persistence of cholera amongst European troops in India is giving very great concern to the authorities, and much thought is devoted to the question of its origin. The *United Service Gazette*, in its last issue, details the substance of a conversation on this subject with "a field officer of great intelligence and of long Indian experience." It says—"We have received from him the strongest confirmation of our previously-expressed opinion, which was and is, that impure drinking-water is the real *fons et origo* of all these cholera outbreaks. It appears that previous to the present year, India had a long continuance of dry seasons, during which fever prevailed, but cholera was almost entirely absent. This year the plains have been flooded with rain, and the surface-water has drained into the wells, carrying with it all the

impurities which might be expected to lie on the surface all about Indian towns or cantonments. We are indebted to our informant in addition for a further, and what we look upon as being a very suggestive, piece of information. It appears that in the latter days of Sikh rule, Meean Meer was the site of Runjeet Singh's camp, and that that camp left behind it enough of abomination both on the surface and under the surface, to poison all the wells in India. During the long succession of dry seasons, these abominations remained where they had been deposited, but when the rains came, it is not at all unreasonable to suppose that they found their way to the wells, and deposited the cholera-germs in the water."

It seems rather a startling proposition that drinking-water may be contaminated by cholera-germs deposited in the soil a quarter of a century previously and washed out by rains. We should be sorry to believe that the present generation might thus be called upon to pay the penalty of the sanitary *laches* of its predecessors, but we can, nevertheless, fully conceive that the drinking-water of Indian towns or camps may become the storehouse of epidemics which only need victims for their development.

Boarding-out of Pauper Children.

SIR CHARLES TREVELYAN has written in reply to those who object to the system of boarding-out of pauper children. He says that the ladies and gentlemen who undertake the superintendence of the orphans know the steady married couples, striving widows, or elderly unmarried women in their respective neighbourhoods who can be trusted as foster parents, and in some interesting cases orphans have been engrafted into the family of the gardener or of the bailiff in charge of the home farm. Many a desolate home has thus been rendered cheerful; and while the largest scale of allowance authorised is still a saving to the ratepayers, the lowest forms an acceptable addition to the narrow incomes of the labouring class. In the manufacturing districts, he adds, the movement has taken a form suited to their special circumstances.

The Adulteration Act and the Vinegar Trade.

THE *Chemist and Druggist* calls the attention of its readers to a warning contained in its advertising columns relative to the sale of adulterated vinegar. It has long been the practice of some unscrupulous persons to give a fictitious strength to these articles by the use of vitriol. This practice will in future render the vendor liable to a penalty of £20 for each offence.

Small-pox in Holborn.

THE greatest number of cases reported by the Medical Officer of Health (Dr. Gibbon) in his former report as occurring in any one week was 13 during the week ending May 13th, from which date they averaged 9 fresh cases weekly up to June 17th, when 12 were reported; they then gradually declined until the middle of November, when a slight increase occurred in the returns for about a month.

The new report just published gives much additional information. Thus we learn from it that since the close of the year 1871 a few sporadic cases have occurred, chiefly in the registered common lodging houses.

This epidemic has certainly proved the most fatal, if

not the most wide-spread epidemic of small-pox, since the passing of the Metropolis Local Management Act, 1855. The next most formidable outbreak occurred in 1863, when small-pox killed 2,012 in London, whereas last year it killed 7,876 persons.

In this district, in 1863, there were 255 cases and 36 deaths (viz., 24 in private houses, and 12 in hospitals); whereas, in 1871, there were 249 cases and 58 deaths, viz., 14 in private houses, and 44 in hospitals.

In 1863 Holborn sent 33 cases into the Small-pox Hospital, of whom 9, i.e., 27 per cent., died; 89 cases into a separate and detached infirmary at the workhouse, and 3, i.e., 3.36 per cent., died; 266 cases were treated in private houses, and 24, i.e., 9 per cent., died.

During 1871 the same district sent 193 into the Hampstead and Homerton Small-pox Hospitals, of whom 44, or 22.8 per cent., died. Out of the 160 cases treated in private houses only 14, i.e., 8.7 per cent., died.

Out of 6,113 patients treated between the 1st of December, 1870, and the 20th of December, 1871, 1,167—i.e., 19 per cent.—died in the hospital. And even this is not the total mortality, as many of these patients were removed for the completion of their cure to convalescent hospitals—the females to the old workhouse of St. Mary's, Islington, where 40 died, and the males to the *Dreadnought* Hospital Ship, where 3 died. These 43 deaths, added to the number actually occurring in the Hampstead Hospital, bring them up to 1,210 deaths in 6,113 patients, or 19.79 per cent.

These returns show an excessively high death-rate of cases treated in the Small-pox Hospital—more than twice as great as that amongst patients treated in their own homes. The only argument in favour of hospital treatment as against home treatment, according to the report before us, is, that it affords more effectual isolation, and is, thereby, supposed to prevent the spread of infection. This theory of isolation in hospital, as applied to the treatment of the very poor, is, it is admitted, undoubtedly good; but, unfortunately, it was unnecessarily applied to many cases which were well and effectually isolated in their own homes; and whenever this can be done, Dr. Gibbon holds that it is as impolitic, in a preventive point of view, as it certainly is in a curative one, to remove cases of small-pox or other infectious diseases into hospital. However, as the Legislature has decreed that isolation should be tried on a large and expensive scale, he thinks it is only due to the metropolitan ratepayers that some inquiry should now be instituted to ascertain why the experiment has so signally failed in a preventive, as well as a curative sense, during the recent epidemic. He seems to think it will be found that isolation—admirable means of prevention as it undoubtedly is—in so very infectious a disease as small-pox, requires to be carried out under very strict and skilled supervision, otherwise its practice causes more disease than it prevents. Persons labouring under small-pox emit the seeds of the disease very copiously into the adjacent atmosphere, and are sure to infect all unprotected persons who come within a moderate distance, as well as articles of clothing, furniture, &c. He asserts that he knows of several instances in which the distemper was taken by persons being allowed to collect around the small-pox ambulance in the street, and from patients who were discharged from the hospital before they were free from infection and without previous disinfection. The practice of sending

small-pox patients unnecessarily through the streets to convalescent hospitals appears to him calculated to spread the disease.

Competency of Medical Practitioners who are not Apothecaries, to Compound Medicines.

WE recently quoted an editorial note of the *Pharmaceutical Journal*, which appeared to infer that Medical men, not being Apothecaries, were disqualified from dispensing. A recent legal decision in England, which we at the time discredited, went to show that a Medical practitioner could not recover the value of medicines unless he were legally empowered to do so by holding the Licence of an Apothecaries' Company. The *Pharmaceutical Journal* quoted in support of this allegation, the opinion of Mr. Glenn, the author of a well-known treatise on the laws affecting Medical men. Mr. Glenn (on the authority of the 31st and 32nd Vict., cap. 121, sections 1, 15, 16, and the 32nd and 33rd Vict., cap. 117, section 1) says that a Medical practitioner, not being a legally qualified Apothecary, may not sell, or keep an open surgery for retailing, dispensing, or compounding "poisons" (*i.e.* articles declared so by statute), unless registered prior to August 11th, 1869, or registered since that date with a diploma which could not be obtained without passing an examination in pharmacy. This regulation does *not apply* to Ireland, but somewhat similar provisions are enacted with regard thereto, by a recent Act—33 and 34 Vict., c. 25.

It is obvious from this statement that no Medical practitioner is disqualified from dispensing or recovering his remuneration for so doing as long as Pharmacy is included amongst the subjects of the examination of the licensing body from which he has taken his diploma.

The English Hospital Dinners.

THE Biennial Dinner of the Old Students of St. Mary's Hospital, Paddington, will be held at Willis's Rooms, on October the 2nd, Spencer Smith, Esq., in the chair. The Annual Dinner of the Past and Present Students and Friends of the Middlesex Hospital Medical College will take place at St. James's Hall on October 1st, T. W. Nunn, Esq., F.R.C.S., in the chair. The Council of the Leeds School of Medicine, with old Students and others interested in the School, will also dine together after the delivery of the President's Address, on October 1st.

Adulteration of Quinine.

THE *Indian Medical Gazette*, in its last number, gives the result of its analysis of twelve samples of *soi-disant* quinine bought in the shops of twelve different native practitioners in Calcutta. Of the dozen samples six were spurious, and consisted in great part of cinchonine.

Army Medical Department.

STAFF SURGEON-MAJOR VEALE has been ordered to Netley for duty, and is to join on the 1st prox. Staff Surgeon Herbert has embarked for St. Helena. Staff Assistant-Surgeon A. L. Brown has been granted six weeks' leave of absence, prior to embarking for Bombay; Staff Assistant-Surgeon Grant is on leave till Nov. 10th next.

The "International" at Omagh.

A MEETING was held the week before last at Omagh, under the auspices of Dr. Maunsell, the Poor-law agent of the *British Medical Journal* in Ireland, with the view of establishing a branch of the London Poor-law Medical Officers' Association in Tyrone. Dr. Maunsell was present, together with five out of the thirty-five Poor-law Medical officers of that county. Seven resolutions were passed with great and commendable unanimity by the four gentlemen present, about two to each person, and the foundation stone of the British Medical Association Agency having been proclaimed with much jubilation, the meeting went home to their dinners.

Portraiture a la Mode.

IT is not an uncommon thing for a man who has made his mark in the world of science, literature, or politics, to write his own biography, and we are not sure that our readers will dispute with us that many lives have been inscribed upon paper which to society were not worth the materials used for their construction; but it would be a very uncommon thing indeed if those biographers exposed their sensitive feelings to the attacks of critics during their lifetime. *Requiescat in pace* is the benediction pronounced over the dead; but this would frequently be reversed were the man alive. Criticism would not then be bound by the tomb, and he would see the mighty mountains of his own conceit topple over one by one beneath the sledge-hammer of the press and public opinion. We are led to this subject by an announcement of our artistic contemporary, *The Graphic*, that it will publish in its early October numbers the portraits of those gentlemen whose names are given to deliver the Introductory Addresses at the opening of the London Medical Colleges. Doubtless the gentlemen concerned will feel flattered for the attention of our contemporary, and will wax doubly eloquent at the thought that eagle-eyed cameras stare them in the face to catch the most telling attitude, the self-satisfied expression, and the elegant wave of the hand. We do not object to this: on the contrary, a spirit of emulation may be engendered, the honours of hospital chairs be more keenly contested, and a little more life and originality of thought be infused into these annual addresses when it becomes known that the eye of the general public will be upon them the next week, and students will no longer be their only censors. We do, however, for obvious reasons, strongly object that these gentlemen should be asked to write their own biographies for publication. 'Tis well to blow one's own trumpet sometimes—as a rule, this is performed by one who has no friend to do it for him; but the gentlemen selected to open the Session at our important schools should be above this, and their own professionally public life be the best biography.

THE next meeting of the British Association will be held at Bradford, on September 19th, 1873, under the presidency of Dr. James P. Joule, LL.D., D.C.L., F.R.S. Belfast was selected for 1874.

THE Senatus Academicus of Edinburgh University has lodged a reclaiming note against Lord Gifford's judgment in favour of the lady student. This will at least have the effect of delaying them on their road to legitimate degrees.

THE Corporation of London are under a legal obligation to re-build dwellings for the poorer classes in the immediate neighbourhood of the Holborn Viaduct within five years from the passing of their Viaduct Act, 1867. The Board of Works have twice reminded the Corporation of their liability in this very important sanitary matter. Inasmuch as the time specified by the Legislature has elapsed without the commencement of these dwellings, the report of the Medical officer of the district says it appears to be the duty of the Board, in the interest of the public health, to take measures to compel the fulfilment of this very wise provision of an Act of Parliament.

MEMORANDA (ANEURISM).

AMONG the anxieties and responsibilities of an active professional life, many useful precepts and important suggestions are forgotten, and the same observations and results are recorded again and again as original. The following affords an example of this fact:—In the last number of the MEDICAL PRESS (No. 1,750, for August) there is an interesting address at the meeting of the British Medical Association, by Oliver Pemberton, Surgeon to the General Hospital, Birmingham, on a modification of the operation of aneurism of the femoral artery. By the usual operation, Dr. Morris informs us, in his tables, the mortality is 24·5 per cent., or as great as amputating the thigh for disease.

In March, 1857, Mr. Pemberton relates a case (D., p. 151) in which pressure was applied to the sac of the aneurism for four hours at a time, so as to retard the circulation. During the first fortnight little good was effected. Then, for eight consecutive days, pressure was applied on an average of seven and a half hours per day, and for nine days, six and a half hours per day. From this time the aneurism diminished in size, ceased to pulsate, and the patient gradually resumed his ordinary occupation as an active sportsman. The remains of the aneurism is an indurated enlargement, the size of a chestnut. He is yet living in his 83rd year, active and well.

In case B., æt. 32, the aneurism had existed for three months. Exercise with occasional manipulation of the tumour accomplished the cure.

As this important treatment has been recommended in a work (a) little known in this country, we shall place before our readers a rational method of treating aneurism described by the author, affording an explanation which we consider worthy of consideration.

Instead of pressing or manipulating gently the sac of the aneurism, press gently upon the distal vessels of the aneurismal swelling with properly regulated stimulating applications over the sac, so as to encourage the formation of consolidated blood in the sac: To understand this effect, Dr. Wise makes an important distinction between consolidated and coagulated blood (b). The former term is employed to designate the preternatural vital change in the blood, when it is converted into a homogeneous red solid mass, or is consolidated into a vital body, which we constantly see removed and deposited, in which John Hunter found vessels, and which is sometimes inflamed and purulent matter is formed, or is changed into bony matter in the aneurismal sac, or into *phlebolites* osseous-looking bodies, or calculi in veins (c). In the latter case

the blood coagulates when its chemical constituents change or when it is removed from the body. The former, in the aneurismal sac, forms hard layers, and terminates, as in the above Case D., in a hard ball, which remains unchanged; but when blood coagulates in the sac it causes irritation and suppurates. In this case the inflammation in the sac extends to the blood vessels connected with it, and consolidated blood fills up these vessels and prevents the direct introduction of purulent matter into the system. This effect is produced by pressure upon the sac; but a better method is to produce pressure upon the distal vessels of the aneurism, to diminish the force of the circulation, with proper regulated stimulating applications over the sac, so as to encourage the formation of consolidated blood in the sac.

Literature.

A MANUAL FOR HOSPITAL NURSES (a).

THIS little book contains much valuable information, but it is doubtful whether it will meet with many purchasers among professional nurses, owing to the high price at which it is published—namely, half-a-crown, for 72 pages, 12mo. We regret to notice in it too many trivial remarks, such for instance as this:—"It becomes the duty of every nurse to see that a constant supply of fresh air is always provided for her patients, taking care that there are no draughts, and that the ward is not made unnecessarily cold." What can be the practical utility of telling nurses that they are expected to solve the problem of providing abundance of fresh air without too great lowering of the temperature, when it is notorious that this is almost impossible, at least in the cold season, in hospitals as hitherto constructed? Again, it is very easy to say, "a well-stuffed hair mattress about six inches thick is the best for the majority of cases;" but the phrase has no definite meaning. A well-stuffed mattress makes a very good bed for the first six months; after that time, however, it begins to get hard and thin, and in the course of the second twelve months of use, is anything but a good bed. All mattresses ought to be taken to pieces, carded, and made up again every six months, as is done in most French houses and institutions, but seldom or never in these islands; and he who puts himself forward as a teacher of nurses ought to know this and to direct attention to it. It seems to us, also, to be a serious defect in a manual for nurses that the important subjects of infection and the use of disinfectants are not so much as once mentioned. There must have been something radically wrong in the sanitary teaching of the school where Mr. Domville was educated to account for this omission. A completely satisfactory book on hospital nursing—one that might compare, for instance, with Miss Le Hardy's "Home Nurse," has yet to be written; for even Miss Nightingale's notes have no pretension to be a practical guide to nursing.

HYGIENE (b).

IT is the wont of a good many members of the Medical Profession to assert that of late years French Medical men are wanting, both in profundity, and in the industry required for the successful study of the science of medicine. This opinion is one worth examining into in detail, but

any person who takes up the various works on hygiene which have issued from the French press, will be likely we believe, to say that in industry at least there is no lack amongst French Medical authors. Indeed, when we look at the brief and scanty treatises upon hygiene, which we possess in the English language, and compare them with the learned work of Dr. Levy now under consideration, we shall feel compelled to acknowledge that neither in learning nor in industry can we at all compete with such authors as Tardieu, Becquerel, or our author. Every student of hygiene should possess this book.

The greater part of the two large volumes which constitute the late M. Levy's splendid work, are occupied with private hygiene. The early part of the first volume treats of the history of the science in the days of Socrates and Hippocrates, when gymnastics were so successfully cultivated, and carries us onward to the days of Galen, Celsus, Moses, the school of Salerno, &c. Hygiene passes out of the hands of the priest gradually into the domain of the man of science and the physician.

He then treats of the *temperaments* and *idiosyncrasies*, the peculiarities of constitution accompanying age and sex, and the proclivities to disease as influenced by such facts. The chapters on sex are peculiarly well done, especially, that one upon diseases peculiar to the male sex, which is always treated in a silly manner by the majority of writers in this country.

There is a most learned disquisition on climate in the first volume, and the question of acclimatisation is thoroughly gone into and solved as far as possible. This is a subject of the highest importance to natives of this colonising country.

The part of the work which treats of soil and habitation, and ventilation, is admirable and exhaustive, and that on drainage is admirable.

The chapters on food, too, are full, and will be found replete with materials useful to the lecturer on this important branch of the subject. There are numerous tables, giving the value of each kind of diet, and comparisons between the dietaries of various armies in Europe are made.

The chapters on bathing are well done, and it is evident that the author is a great admirer of what is now denominated "hydropathic" régime. His observations on drinks show that theoretically he is an admirer of pure water as a drink for the healthy; but he speaks favourably of both tea and coffee as beverages, on the whole tending to lengthen life, when partaken of moderately. He is a foe to tobacco, but speaks his convictions mildly, and with a tender feeling of regret in objecting to the herb which so often gives pleasure to the soldier or sailor.

In the matter of public hygiene, he acknowledges the evils of over-population, following in this the views of the great French writers on this subject, such as Say, Garnier, Becquerel, and Villermé, all disciples of Adam Smith, and the great English school of political economy.

We might go on for a great deal longer, but merely wish to express our opinion in brief, that the work on hygiene by the late M. Levy, is by far the most complete and valuable work extant on this subject, and that all English writers on such subjects, and students of what is called state medicine, should by all means have the work in their library.

THE MODES OF ORIGIN OF THE LOWEST ORGANISMS (a).

THE BEGINNINGS OF LIFE (b).

THESE volumes constitute a very able and elaborate defence of the doctrine of Heterogenesis or the evolution

(a) "The Modes of Origin of the Lowest Organisms." By H. Charlton Bastian, M.D., &c. Macmillan. 1871.

(b) "The Beginnings of Life." By H. Charlton Bastian, M.D., &c. Macmillan. 1872.

of life, popularly known as "Spontaneous Generation," and now styled by Dr. Bastian "Archebiosis," and a complete array of experimental and other evidence in its favour. The case of the Heterogenists in the present state of public opinion on philosophical and religious subjects, has to be conducted in the face of almost overwhelming prejudices, which will long prevent the evolutionary theory of life from being generally accepted. But such advocacy as that of Dr. Bastian must have great influence, in reconciling to that theory the rising generation of students and thinkers. Were these prejudices, however, to be set aside, there would remain little serious opposition of a scientific character to the doctrines in question, except that of the French *savant*, Pasteur, who may be considered the apostle of the contrary doctrine of Panspermism. Almost all other observers with whose writings we are acquainted concur in supporting the doctrine of Heterogenesis. Thus, Pouchet, Joly, Musset, Mantegazza, Wiyman, Schaffhausen, Bennett, Meunier, Child, Cantoni, Frémy, Sanderson, Le Gros, Onimus, and Garne, have all been constrained by the nature of the results attained by them from their experimental researches, to declare more or less decidedly in favour of evolution. But Pasteur, owing to his manipulative accuracy and ability in stating his case, is in himself a host. The trustworthiness of his experiments has never been seriously doubted, and if the decision of the question were made to rest on his results as interpreted by himself, he would undoubtedly be pronounced to have made good his position (a). Other observers, however, have not been content merely to repeat Pasteur's experiments; they have devised new ones, the results of which seem to entitle them to give an interpretation to Pasteur's very different from that put forward by the latter. Thus, the celebrated Alpine experiments, contrived for the purpose of showing that aerial germs, which, according to the panspermists, abound in the atmosphere at low levels, are absent at great altitudes, and wherein boiled and hermetically sealed flasks, containing organic infusions, exhibited no living organisms after being made to communicate with the external air, when repeated, with more concentrated infusions, by MM. Joly and Musset, acting in concert with M. Pouchet, manifested an abundance of infusorial life (b). The latter observer, who is entitled to be considered the leader of the modern heterogenists, had previously demonstrated that the production of organisms and the peculiar character of those produced were to a great extent determined by the nature of the substances entering into the composition of the infusions, and not by any germs conveyed into them from the air to which they were exposed after the boiling process (c). Again, Professor Wyman, of Cambridge, U.S.A., by working with small quantities of infusion in proportion to the size of his flasks, and consequently with relatively greater volumes of calcined air, hardly ever failed to develop organisms in experiments which, in the hands of Pasteur, had produced none; but found that when the boiling, which Pasteur was content to continue for ten minutes, was prolonged for five or six hours, no organisms were ever produced, even under the above apparently favourable conditions (d). The conclusion arrived at by
